Acerca de este libro

Esta es una copia digital de un libro que, durante generaciones, se ha conservado en las estanterías de una biblioteca, hasta que Google ha decidido escanearlo como parte de un proyecto que pretende que sea posible descubrir en línea libros de todo el mundo.

Ha sobrevivido tantos años como para que los derechos de autor hayan expirado y el libro pase a ser de dominio público. El que un libro sea de dominio público significa que nunca ha estado protegido por derechos de autor, o bien que el período legal de estos derechos ya ha expirado. Es posible que una misma obra sea de dominio público en unos países y, sin embargo, no lo sea en otros. Los libros de dominio público son nuestras puertas hacia el pasado, suponen un patrimonio histórico, cultural y de conocimientos que, a menudo, resulta difícil de descubrir.

Todas las anotaciones, marcas y otras señales en los márgenes que estén presentes en el volumen original aparecerán también en este archivo como testimonio del largo viaje que el libro ha recorrido desde el editor hasta la biblioteca y, finalmente, hasta usted.

Normas de uso

Google se enorgullece de poder colaborar con distintas bibliotecas para digitalizar los materiales de dominio público a fin de hacerlos accesibles a todo el mundo. Los libros de dominio público son patrimonio de todos, nosotros somos sus humildes guardianes. No obstante, se trata de un trabajo caro. Por este motivo, y para poder ofrecer este recurso, hemos tomado medidas para evitar que se produzca un abuso por parte de terceros con fines comerciales, y hemos incluido restricciones técnicas sobre las solicitudes automatizadas.

Asimismo, le pedimos que:

+ *Haga un uso exclusivamente no comercial de estos archivos* Hemos diseñado la Búsqueda de libros de Google para el uso de particulares; como tal, le pedimos que utilice estos archivos con fines personales, y no comerciales.
+ *No envíe solicitudes automatizadas* Por favor, no envíe solicitudes automatizadas de ningún tipo al sistema de Google. Si está llevando a cabo una investigación sobre traducción automática, reconocimiento óptico de caracteres u otros campos para los que resulte útil disfrutar de acceso a una gran cantidad de texto, por favor, envíenos un mensaje. Fomentamos el uso de materiales de dominio público con estos propósitos y seguro que podremos ayudarle.
+ *Conserve la atribución* La filigrana de Google que verá en todos los archivos es fundamental para informar a los usuarios sobre este proyecto y ayudarles a encontrar materiales adicionales en la Búsqueda de libros de Google. Por favor, no la elimine.
+ *Manténgase siempre dentro de la legalidad* Sea cual sea el uso que haga de estos materiales, recuerde que es responsable de asegurarse de que todo lo que hace es legal. No dé por sentado que, por el hecho de que una obra se considere de dominio público para los usuarios de los Estados Unidos, lo será también para los usuarios de otros países. La legislación sobre derechos de autor varía de un país a otro, y no podemos facilitar información sobre si está permitido un uso específico de algún libro. Por favor, no suponga que la aparición de un libro en nuestro programa significa que se puede utilizar de igual manera en todo el mundo. La responsabilidad ante la infracción de los derechos de autor puede ser muy grave.

Acerca de la Búsqueda de libros de Google

El objetivo de Google consiste en organizar información procedente de todo el mundo y hacerla accesible y útil de forma universal. El programa de Búsqueda de libros de Google ayuda a los lectores a descubrir los libros de todo el mundo a la vez que ayuda a autores y editores a llegar a nuevas audiencias. Podrá realizar búsquedas en el texto completo de este libro en la web, en la página `http://books.google.com`

This is a digital copy of a book that was preserved for generations on library shelves before it was carefully scanned by Google as part of a project to make the world's books discoverable online.

It has survived long enough for the copyright to expire and the book to enter the public domain. A public domain book is one that was never subject to copyright or whose legal copyright term has expired. Whether a book is in the public domain may vary country to country. Public domain books are our gateways to the past, representing a wealth of history, culture and knowledge that's often difficult to discover.

Marks, notations and other marginalia present in the original volume will appear in this file - a reminder of this book's long journey from the publisher to a library and finally to you.

Usage guidelines

Google is proud to partner with libraries to digitize public domain materials and make them widely accessible. Public domain books belong to the public and we are merely their custodians. Nevertheless, this work is expensive, so in order to keep providing this resource, we have taken steps to prevent abuse by commercial parties, including placing technical restrictions on automated querying.

We also ask that you:

+ *Make non-commercial use of the files* We designed Google Book Search for use by individuals, and we request that you use these files for personal, non-commercial purposes.

+ *Refrain from automated querying* Do not send automated queries of any sort to Google's system: If you are conducting research on machine translation, optical character recognition or other areas where access to a large amount of text is helpful, please contact us. We encourage the use of public domain materials for these purposes and may be able to help.

+ *Maintain attribution* The Google "watermark" you see on each file is essential for informing people about this project and helping them find additional materials through Google Book Search. Please do not remove it.

+ *Keep it legal* Whatever your use, remember that you are responsible for ensuring that what you are doing is legal. Do not assume that just because we believe a book is in the public domain for users in the United States, that the work is also in the public domain for users in other countries. Whether a book is still in copyright varies from country to country, and we can't offer guidance on whether any specific use of any specific book is allowed. Please do not assume that a book's appearance in Google Book Search means it can be used in any manner anywhere in the world. Copyright infringement liability can be quite severe.

About Google Book Search

Google's mission is to organize the world's information and to make it universally accessible and useful. Google Book Search helps readers discover the world's books while helping authors and publishers reach new audiences. You can search through the full text of this book on the web at `http://books.google.com/`

INDEX TO ELECTRICITY,

VOLUME VIII.

Nos. 1 to 26, Inclusive.

JANUARY 16---JULY 10, 1895.

* * *

A

Accumulator, The Schafer-Heinemann, by A. M. Gibson, 87.
Accumulator, Extraordinary, 200.
Adams, Alton D., The Best Metal for Field Magnet Frames, 41.
Advice to the "Electrical Engineer," 353.
A Large Portable Plant, 192.
Allegheny Plant, That, 124.
Alternating Currents, An Apparatus for Measuring Difference of Phase Between, by Louis Derr (Illustrated), 328.
Alternating Current Curves, Method for Obtaining, by Dr. Louis Duncan, 100.
American Bell's Weakness, 211.
American Institute of Electrical Engineers:
  93d Meeting, 10, 21; Postponement of February Meeting, 38, 95; H. Ward Leonard's Views, 111, 113, 122, 135, 149, 156, 184, 205, 224, 271; Niagara Falls Meeting, Preliminary Programme, 300, 317; 12th General Meeting at Niagara Falls, 335, 345.
Amstutz, N. S., Low Rail Joints of Street Railways and Their Prevention, 54.
An Oversight, 3 7.
Anthony, William A., Underwriters' Rules, 202; Discussion, 227, 242.
An Enlarging Business, 58.
Ansonia Company Revived, The, 112.
Another Self-Propelled Vehicle Competition, 6.
Arc Carbons and the Rating of Arc Lamps, by L. B. Marks, 190; Discussion, 203, 214.
Arc Dynamos, Large, by Chas. N. Black, 133; Discussion, 208.
Arc Lamp News, 138.
Are They Cramped for Room, 244.
Armature Reaction, A Method for Preventing, by Harris J. Ryan and Milton E. Thompson, 144.
Armstrong, Lord, Recent Experiments on the Electric Discharge (Illustrated), 300, 314.
Artificial Lights, The Intrinsic Brilliancy of, 8.
Atkinson, A. A., Opportunities in Electrical Engineering, 200, 2 8.
Atlantic Cable, Projectors of the, 273.
A Truthful Director, 15.
Attix Tube and Wire, 149.

B

Baily, F. G., The Scientific Foundations of Electrical Engineering, 157.
Baltimore Belt Line Equipment, The, 353.
Bates Case Ends Litigation, Decision in the, The Lamp Field Free Forever, 107.
Battery of Extraordinary Strength, A, 243.
B. E. G., Decorative Lighting, A Fertile Field for Architects and Designers, 157.
Bell, Dr. Louis, The Monocyclic System, 97; Discussion, 109.
Benedikt, V. M., Electric Power in Factories and Mills, 341.
Bernard, R. M., Church Illumination, 67.
Black, Chas. N., Large Arc Dynamos, 133; Discussion, 203.
Book Reviews:
  Central Station Bookkeeping and Suggested Forms, with an Appendix for Street Railways, by Horatio A. Foster, 10; "Electric Power," 31; The New Science Review, 32; How to Build Dynamo Electric Machinery, by Edward Trevert, 57; Electric Lighting Plants—Their Cost and Operation, by W. S. Buckley, 57; Elementary Lessons in Electricity and Magnetism by Silvanus P. Thompson, Electric Transmission of Energy by Gisbert Knapp, 100; Proceedings of the International Electrical Congress Held in the City of Chicago Aug. 21st to 25th, 1893 (American Institute of Electrical Engineers), 161; A Text Book on Electro-Magnetism and the Construction of Dynamos, Vol. I, by Dugald C. Jackson, 191; Operation of the Vibratory Circuit (by Polar and Depolar Sympathetic Interchange as Associated with the Transmitter), by John W. Keely, 273; Street Railway Investments, A Study in Values of, by Edward E. Higgins, 284.
Boston Notes: 33, 45, 113, 128, 216.
Boston, Saturday Half-Holidays in, 224.
Brackett, S. H., The Magnetic Properties of Iridium, 8.
Brinton, Explosion at, 39.
Brooklyn Electrical Society: 27, 39, 138, 205, 256.
Brooklyn Edison Station, Reception at the, 168.
Brush Windmill Lighting Plant, The Great, 65.
Brush Works, Closing of the, 244.
Bryant Switch Company Enjoined, The, 256.
Buffalo-Niagara Transmission Scheme, The, 149.
Business Hints: 275, 287, 3 4, 319, 331, 348, 359.

C

Cable Signaling, Experiments in, by Patrick B. Delaney, 8.
Cables and Tricycles, Triplicate, 202.
Can They Economize, 52
Cathode Rays, by M. de Kowalski, 204.
Cauro, J., The Electrostatic Capacity of Coils, 292.
Central Stations, Storage of Energy Essential to Economy of Working in, by Nelson W. Perry, 93, 120, 135.
Chicago Edison Company, 316.
Church Illumination, by R. M. Bernard, 67.
Cincinnati and Dayton Electric Line, The, 161.
Cleveland Convention, The, 9, 27; Tenth Annual Meeting of the N. E. L. A., 89; The Commercial Side, 95; Those in Attendance, 101.
Cleveland, The Lighting of, Birthplace of the Arc Lamp, 73.
Coal Gas, The Future of, 244.
Coal, Waste of, 242.
Columbia College, Advanced Electrical Work at, 213.
Correction, A, 107.
Commercial Paragraphs:
  Metropolitan Electric Company, 11; Partridge Carbon Company, 12.—W. S. Hill Electric Company, A New High Potential Switch, Wallace & Sons, The Joseph Dixon Company, 23.—The Simplest Cleat, The Keystone Electric Company, Notice of Removal (Electric Storage Battery Company), Warren Engine Dynamo Company, The Boudreaux Dynamo Brush Company, Annual Meeting of the Standard Underground Cable Company, 35.—U. S. Mineral Wool Company, Wallace & Sons, Metropolitan Electric Company, 47.—Efficiency Test of the Stratton Steam Separator, Central Electric Company, Hart & Hegeman Manufacturing Company, 60.—C. W. Hunt Company, Abendroth & Root, 88; Onondaga Dynamo Company, E. G. Bernard Company, Metropolitan Electric Company, 4.—Electric Engineering and Supply Company, Electrical Engineering Company, 103, 104.—Metropolitan Electric Company, T. E. Beden, Mica Mining Company, Electric Storage Battery Company, Walker Manufacturing Company, Siemens & Halske Generators in Philadelphia, Bristol Recording Voltmeters, Wagner Transformers, Mather Company's Sales, 115.—Packard Lamps, The Mather Electric Company, The Partridge Carbon Company, Interior Conduit and Insulation Company, Wm. B. Vansize, The Hornberger Electric Company, 128.—Partrick & Carter's House Goods Specialties, Mather Company's Sales, Micanite, 140.—Mather Electric Company, Metropolitan Electric Company, Standard Electric Company, A New Water-Wheel Governor, 151.—Metropolitan Electric Company, Electrical Installation Company, Phœnix Rubber Insulating Paint, Mather Electric Company's Sales, Walker Manufacturing Company, Premier Motors and Batteries, 164.—Lundell Alternating Fan Motor Outfits, Phœnix Interior Telephones, 194; Keystone Electric Motors, The Hagan Boiler, Walker Company's Sales, A 4,000 Horse-Power Goubert's Heater, Mather Electric Company, Partrick & Carter, Beacon Lamp Company, 195.—Independent Electric Company, Packard Lamps, Metropolitan Electric Company, 208; Fort Wayne Electric Corporation's New Multipolar Dynamo,

218527

219; Columbia Incandescent Lamp Company, Metropolitan Electric Equipment Company, 220.—Cutter's Specialties, Supplies for the War Department, Babcock & Wilcox, The Capo Farad Battery and Appliance Works, Clark Electric Company, Siemens & Halske, 235.—Central Manufacturing Company, Eddy Electric Manufacturing Company, 246.—Telephone Apparatus of Danbury Electrical Works, Wagner Fan Motors, The Vance Electric Company, The Western Telephone Construction Company, The Boynton Multivolt Battery, Adams-Bagnall Electric Company, 247; Fred. M. Locke, 248.—M. and B. Transmitters, Arc Lamps and Fixtures, Manhattan General Construction Company, Bal-ley & Bryner, 259.—Test of Heine Boilers, 275. —Columbia Incandescent Lamp Company, Boyts, Porter & Company, Walker Manufacturing Company, Central Electric Company, 287.—Standard Electric Company, C. W. Hunt Company, 304.—New York and Ohio Company, Crouse-Tremaine Carbon Company, Emerson Electric Manufacturing Company, Indianapolis Electric Company, Law Battery Company, Westinghouse Machine Company, Standard Electric Company, Central Electric Company, 319.—Emerson Electric Manufacturing Company, Wagner Fan Motors, George Cutter, 331.——American Incandescent Lamps, Bryan-Marsh Company, 348.
Communications:
Electropoise, Letter from Thomas M. Smith, 4; The La Roche Assignment, 22; The National School, 28; Electropoise, 52; S. D. Greene, Interesting Information, 63; Perkins Lamp Company, 138; Electropoise, Letters from O. A. Busard, Wm. L. Clarke, H. K. Long, 177; The Undiscovered Field, 183; The Two-Phase System, John F. Kelly; The Electropoise, Calvin P. H. Vary, 204.
Correction, 167.

ELECTRICITY.

Published every Wednesday by the

ELECTRICITY NEWSPAPER CO.

B. E. GREENE, PRES'T. L. J. MONTGOMERY, SEC'Y.

PUBLICATION OFFICE:

6 Park Place - New York

EDITORS:
NELSON W. PERRY.
BURTON E. GREENE.
R. H. WILLOUGHBY.

SUBSCRIPTION RATES:

United States,	$2.50
In Clubs of Five or More,	$2.00
Foreign Countries,	$4.50
Single Copies,	10 Cents

ADVERTISING RATES:

As ELECTRICITY reaches all classes interested in electrical work, its value as an advertising medium can be readily appreciated. Rates will be sent on application.

Changes for advertisements should reach the office not later than the Saturday preceding the date of publication.

ENTERED AT THE N. Y. POST OFFICE AS MAIL MATTER OF THE SECOND-CLASS.

TRADE SUPPLIED BY
THE AMERICAN NEWS COMPANY,
THE WESTERN NEWS COMPANY,
And their Agencies in all Principal Cities.

N. E. L. A.—The next annual meeting of the National Electric Light Association will be held at Cleveland, O., February 19-21, 1895. Every concern interested in either lighting or railway work should be represented in the membership of this body, and should have at least one representative at the Cleveland meeting. The Secretary is Mr. Geo. F. Porter, 136 Liberty street, New York.

EDITORIAL NOTES.

Toronto Bribery Matters. The city of Toronto has set an example worthy of being followed by many other municipalities in making a thorough and judicial investigation of the charges of bribery and corruption brought against her Board of Aldermen. The investigation has covered several weeks, and the results have been tersely given in Judge MacDougall's reports to the Mayor.

The part of this report which we reproduce this week reads, in view of present prices and conditions in the electrical trade, like ancient history; yet it is only a little more than two years old. In that two years what changes have taken place!

The price of railway apparatus now is down to very near the figure which the G. E. Company was ready to pay then as a bribe to two Aldermen for each equipment sold. This drop in price is not a cause for rejoicing, but there is ample cause for it in the fact—and it is a fact—that the days of giving bribes to secure contracts are about over. There may occasionally be an isolated case, but the disease is practically eradicated.

The Thomson-Houston Company, the great exemplar of bribery and corruption, and its successor, the G. E. Company, conducted on similar lines, have come to grief. And the one fundamental cause for their failure was their dishonesty. Agents were instructed to give bribes; their expense accounts were passed by the president of the company, C. A. Coffin. It did not take these agents long to learn that bribery could be worked both ways, and they were soon accepting bribes to use their efforts to make unbusinesslike trades for their company. Once aware that their employer was fully cognizant of the roguery practised, they did not fear exposure in their own company. They knew they were safe—and they were. A special agent of the company has stated as a solemn fact, within a week, that in his long experience he never had reported that an agent was stealing from the company without seeing that agent not only retained but his salary raised within a month after the report.

The cause of the G. E. Company's failure is laid upon the district office plan. The plan itself was all right. But when every man in those offices knew that there was rottenness and corruption just above him, why should he hesitate to line his own pocket? What incentive was there to work for the best interests of his company?

If the policy of the company had been honest its failure would have been less marked and would have created more sympathy.

It is pleasant to know that this plan of business has been succeeded by something better, even if less money is made by the selling companies. True, the reminders of it have not yet passed out of sight. B. E. Sunny is still in charge of the Chicago office of the G. E. Company—an office where fights over the spoils among employees became matters of public knowledge. C. A. Coffin, the head of the entire system, without whose knowledge it could not have been carried on for one month, is still the president of the company.

ELECTRICITY does not desire to take to itself all the credit for the improved and more honorable conditions of trade; but we are proud that our share in the reform has been conspicuous and creditable. It was the knowledge that ELECTRICITY was ready to print the facts, more than anything else, that has led to the discontinuance of the policy of bribery as a means of selling goods.

* * *

THE Cataract General Electric Company are making another effort to secure the repeal of the law authorizing the Superintendent of Public Works to make further grants for transmission lines along canal lands. The grab which this company worked through rests already under something worse than suspicion, and we doubt if the present Legislature will care to be mixed up in the matter.

General Electric. There have been, so far as we know, no answers published to the questions propounded in these columns last week to the Board of Directors and officers of the G. E. Company, yet they all must be answered, and before many weeks.

Amid all the rubbish given out to the financial agencies and to the press, there occasionally appears something which sheds a little light on the intentions of the directors in regard to reorganization. ELECTRICITY does not need this information. Two or three weeks ago we stated their intentions as to the kind of report which will be issued in April. Last week Kiernan's Agency gave out the following:

> The committee of General Electric directors appointed at the last annual meeting to consider the advisability of reducing the capital stock of the company is expected to render its report at the annual meeting in April.
>
> It is understood the committee will report in favor of a reduction of $13,000,000 to $15,000,000 in the common stock.
>
> The company will close down its works the latter part of this month for a week or so to take inventory. Officials say the annual report will make a very good showing. It is even believed in some quarters that 8½ per cent. was earned on the common during the calendar year.

The first part of the above is only partially correct, the inference deducible from the latter part is totally incorrect.

And if any attempt is made this year to issue a false report of affairs, as was done in the two preceding reports, it will be a dangerous proceeding for the responsible parties. There are stockholders who feel that they have been humbugged long enough, and who propose this year to know the facts. The annual meeting in April next will not be a cut-and dried affair. There will be a lively time at best, and it will not be safe for the man who offers the report to say that he has come unprepared to answer questions. There will be many questions to answer, and they will either be answered at the annual meeting or in a court-room soon afterwards.

The General Electric Company has nearly run its course; it cannot exist much longer under present conditions and present management. Would it not be well for those directors who can prove the innocence of their connection with the scheme to come forward and make their excuses to the public for allowing their names to be used to humbug investors? The responsibility for all the deceit and misrepresentation rests somewhere. Where does it rest? Speak up, Mr. Coster, Mr. Twombly and Mr. Coolidge.

Can any one be expected to believe that the company has made any money this year? When the facts are clearly presented from the books, as they will be sooner or later, it will be shown that ELECTRICITY's statement was correct; that the reduction in assets for the year is greater than the debts paid and bonds retired, and that the cash has not increased. This fact cannot easily be explained away.

The ultimate total collapse of the organization is inevitable, and it will be welcomed by those having the best interests of the industry at heart. It means that bribery and general thieving have no place in the conduct of a commercial enterprise; that the public has placed the seal of emphatic disapproval on the methods adopted to sell goods, on the plan of financiering, and upon every important feature of the company's management.

The air will be clearer when every vestige of the present management has been eliminated.

* * *

The Welsbach Light. The *Progressive Age*, an advocate of the gas interest, has attempted to answer the arguments recently printed in ELECTRICITY against the Welsbach light. Our contemporary accuses ELECTRICITY of manufacturing testimony, and prints denials from Mr. E. P. Gleason and President Gawtry of the Consolidated Gas Company of the interviews ascribed to them in our article. We have manufactured neither interviews nor news.

When our Welsbach matter had been prepared by the editor, having no member of the staff at liberty to make a tour of the city for the purpose of securing interviews, we engaged Mr. G. Wilfred Pearce, a newspaper man of some experience, to do that work for us. His interviews were accepted as genuine and paid for by us at regular rates. If those of Messrs. Gleason and Gawtry were bogus, Pearce is convicted of the worst offence known among newspaper men, and is not likely to have an opportunity to swindle anyone else in like manner.

Our apology and this explanation is cheerfully made to these gentlemen, which we hope will be accepted in the spirit in which they are offered.

As to the *Progressive Age*, however, we have this to say, that it makes absolutely no reply to our arguments against the Welsbach light. It makes an exceedingly awkward and puerile attempt to evade the question by saying: "We lack both space and the incentive to *attempt* to set our contemporary straight; possibly we may entertain the thought that it prefers to continue in its present course, in keeping with the old saying 'None so blind as those that will not see!' Nor have we a desire to give to our friend *elementary instruction in chemistry*, therefore we *leave its minor criticisms* on that score to turn to more serious matters." (The emphasis is ours.) And then it devotes two columns of matter to calling our attention to the two fraudulent interviews above referred to. For this latter service and the opportunity to set ourselves right we are under great obligation to our contemporary. But let us look at its argument (?): It quotes the old saying that there are "none so blind as those that will not see." We quoted the report of the Municipal Council at Vienna (the birthplace of the Welsbach light) when considering the proposition to introduce the light into the schools as follows: ". . . that, besides, the glare and color of the light *attacked the retina* of the eye, especially at the commencement. . . .

"Conformably with this report, it was decided by the referendum to *decline to permit* the introduction of the Auer incandescent burner into the schools."

It would seem from this that our contemporary when discussing the Welsbach light would better have paraphrased the quotation somewhat and made it read "There are none so blind as those who have habitually used the Welsbach light."

As to teaching us elementary chemistry, the idea is almost as amusing as it was for the *Progressive Age* to print as arguments statements from three different authorities (?), one of whom flatly contradicted himself on a vital point, and then described his methods of arriving at unreliable results, another of whom disagreed with the first, and the third who bent his energies to prove that carbonic oxide gas was not poisonous anyway. The same energy expended in the same way to prove that arsenic or prussic acid are not poisonous would be quite as effective and certainly quite as appropriate, since the burden of the first two quotations was to prove that no carbonic oxide existed.

Such trifling facts as that the light tends to destroy the sight of those who use it, that its products of combustion tend to destroy the health of those who sit under it, that the cost of renewals exceeds that of any other artificial light known, and that the care required exceeds that required to keep a kerosene lamp in good order, are unworthy of the attention of our contemporary—so it says. We think the *Progressive Age* did the best it could do, however, in ignoring the facts and attempting to divert attention from them.

* * *

What is the Matter with New York? It is not too early for those who are anxious to secure the 1896 meeting of the National Electric Light Association for New York City to begin the work which will convince the members that this is the proper place for that year.

ELECTRICITY is confident that a majority of the members would look with favor upon New York if the arguments were properly presented. We can offer them all that can be had in any other city and a great deal more.

An entertainment fund could be raised large enough to distinguish New Yorkers as hosts; the Grand Central Palace could be secured for exhibition purposes, and no other building in the country could excel it for the purpose.

New York wants the meeting, and if she tries to get it she can win.

Thomson Regulator Patent Void

Suit Decided in Favor of Western Electric and Sperry Companies.

(Special to ELECTRICITY.)

CHICAGO, Jan. 14.—In the long-fought suit of the Thomson-Houston Company vs. Western Electric Company, for infringement of the Thomson Regulator patent, Judge Grosscup has decided the Regulator patent void on the ground of no invention in view of the admitted state of the art at the time the patent was issued, 1883. He decides that a higher degree of mechanical and inventive skill is expected and required in the electrical field than in other lines. The decision overrules that of Judge Colt in the Citizens' case at Boston.

This case had been in litigation for four years and is a decisive victory for the independent companies.

Followed by a favorable decision in the Bate case, the General Electric Company will be left without a leg to stand on.

ELECTRICITY extends congratulations to the defendant companies, who have fought quietly and persistently, and to Messrs. Barton & Brown, who have conducted their clients to victory.

Under the Searchlight.

Views and Opinions on Timely Topics.

Too Much Johnston.

Mr. W. J. Johnston, publisher of our padded contemporary, the *Electrical World*, who has done all in his power to degrade the profession of journalism, to bedevil not only the electrical newspaper business but the entire trade, has lately deluged advertisers with bushels of circular matter which it is difficult to believe could be prepared by a sane publisher.

He has been tolerated too long, and we submit that it is time for those who patronize his paper to give a little thought to the subject of the man and his methods.

For years he has carried along nearly all the bankrupt concerns in the business, depending upon his good-paying customers for enough profit to enable him to carry without returns all their dead-beat competitors. The pages of the *World* are full of these concerns, many of whom have not paid a dollar in a year. Once in a while, when one of them fails, we learn the facts beyond dispute. Not many months ago one of them offered to give Electricity an advertisement on the same terms as he got from the *World*--he said he had not paid a dollar in three years. He said, also, he had tried the *Electrical Review*, and they had not treated him fairly—they sued him for his account when long overdue.

Let any sound concern, in any line of business, scan the pages of the *World*, and see if most of its bankrupt competitors are not occupying equally desirable positions with its own advertisement.

Can any other publication be found offering such insults to legitimate advertisers ?

Puffed up with the idea that he has made the trade what it is, he now invites people to drop all other papers and give to the *World* ALL their patronage. Does he suppose that the trade can be made to forget that the other journals have all done important work in extending the scope of the business in spreading the knowledge of the art ?

Does he stop to think that he cannot find one successful advertiser in the world to subscribe to his theory that advertising should be done in one publication only ? The subject is scarcely worth ten lines of argument.

He has sent out volumes of lying statements, which grow bolder and more absurd every week.

His map showing circulation by States has not a correct figure in it. His statement of total circulation is a lie, and we challenge him to produce the names of 4,000 *paid subscribers*—people who have paid an annual subscription to the *Electrical World* within twelve months.

We will wager $200 that he cannot produce this list, the winner to pay the $400 into the treasuries of the A. I. E. E. and the N. E. L. A., evenly divided.

He has done nothing but insult the people who have made him what he is since the time when he sold out the telegraph operators, whose support had made the existence of the *Operator* possible.

Having received several orders to discontinue the advertisements of those who could no longer endure his insulting letters, he answers them that he is glad they quit, that it is just too sweet for anything to be rid of them : this to the largest and best paying advertisers in the trade.

It is time for a great many men to ask themselves the question, Can we continue to patronize the *Electrical World* and maintain our self-respect ?

An Electrician's Heinous Crime.

His Severe Sentence.

Judge.—You are an electrician, you say, and you have been convicted of stealing a copy of Electricity from your employer's desk before he had time to read it.

Prisoner.—True, your honor, I could not wait.

Judge.—The offence is a serious one and is occurring too often. You are sentenced to solitary confinement for six days and to read the editorial page of the *Electrical World* twice every day. And may God have mercy on your soul.

* * *

Can This Asset Be Marked Up ?

The books of the G. E. Company show that they hold $119,000 securities of the Ottawa (Ill.) Street Railway Company.

The company has lately taken in about $18 per day or about one-half to one-third of operating expenses. They have now served notice on the Mayor that they will cease running cars and their franchise will be surrendered. The equipment is worthless except for junk.

Can this asset be marked up towards correcting the $12,500,000 impairment of G. E. capital ?

* * *

The following has been received from an advertiser. The full page advertisement referred to appeared in a recent issue of the *Electrical World* :

To the Publisher of Electricity.

Dear Sir : Your favor of the 10th inst. received ; the matter of full-page advertisement to which you called our attention was not authorized.

* * *

A gentleman who has played a leading part in the development of the electrical business for fifteen years writes as follows :

My Dear Greene :

The last number of Electricity was a soaker. I wish you would send a copy to my office regularly. We will burn 'em up yet !

General Electric.

What is Said of It Nowadays.

Notes and Comments from Various Sources.

(From the Evening Advertiser, January 9.)

The stockholders of General Electric will do well to bear in mind several basic facts concerning their company which are in danger of being obscured. The first of these facts is that, while it is perfectly true that one-half of their stock represents nothing at all, except presumably some shadowy kind of item which might be described as "good will," nevertheless their stock is entitled to the reversion of the company's future earnings. If the company can earn in a bad year, such as the year ending December 31, something on the stock, it matters very little whether one-half of that stock represents practically nothing of book value, or whether it is represented by real assets. The stock of an industrial company is valuable only for its earning power.

This impairment of General Electric capital is by no means so vitally important as has been generally thought. It represents, no doubt, a dead and irrecoverable loss. No doubt the symmetry of the balance sheet would be much improved by the cutting in two of the company's capital stock, and elimination of the debit to profit and loss. How, nevertheless, can such an operation impair the earning power of the remaining half of the capital stock? What does it matter to the stockholder whether he receives, for example, 4 per cent. on $100 of stock or 8 per cent. on $50 of stock ? Would not the stock market estimate the $50 of stock at precisely the same value as the $100 in such a case ?

The facts of the case, as far as General Electric is concerned, the *Commercial Advertiser* believes to be as follows, and it has what it considers good authority for the statement. The electrical business in this country, partly by extreme and bitter competition, chiefly at the hands of an extremely well equipped company, viz., Westinghouse, has been brought to a state of minimum profits. This is especially true with regard to street railway equipments. Naturally, the General Electric Company has suffered the loss of considerable business, owing to its financial weakness at the critical moment, and has been obliged to take whatever business was left at very low prices. Notwithstanding this, however, the statement is made by an official of the company that the earnings during the year just closing would have been sufficient to pay something like 4 per cent. on the stock. If this is true, and there ought to be at least a fair chance of its being true, it is evident that, partially crippled as the concern was, it is still able to do business at a profit in bad times. If it is not true, it is to be presumed that the annual report will show what is the truth.

The object of these remarks, as already stated, is to advise stockholders to wait for the annual report before parting with their stock.

For some weeks past there has been a good deal of talk about a newspaper attack shortly to be made on the General Electric Company. Short sales of the company's stock have been made in the market, possibly in connection with this, the majority of these having been made three weeks ago. The murder is now out in the shape of a long criticism of the company's affairs in the trade paper known as Electricity.

It is unnecessary for present purposes to assume that the proprietors or the editor of Electricity have been personally concerned in the "bear" attack on the stock. As far as argument about the matter goes, it is assumed that the article in question is simply an honest endeavor to tell the public what Electricity considers to be the real facts of the case. With so much by way of premise, it seems advisable to say a few words of warning to the public in general and the stockholders of General Electric in particular. In a word, stockholders in the General Electric Company are hereby advised to disregard absolutely and entirely all information concerning their company that may be published between now and the date of publication of the company's annual report. There is sufficient doubt existing with regard to much of this alleged information to make it advisable that nobody should attach very great importance thereto. The last annual report of the company was, on the whole, fairly satisfactory in point of detail and completeness. There was no clear evidence of the facts having been covered up. There was very clear evidence that a leaf had been turned, as far as the company's methods of business were concerned. Since that time, of course, there has been a period of intense depression in the electrical manufacturing business, as indeed in all other manufacturing businesses.

The financial writer of the *Advertiser* concedes the independence of Electricity in its comments on the G. E.

We regret that we cannot extend to him the same courtesy. Either his knowledge of the subject is so limited that he has no business to write a line for any paper in regard to it, or, if knowing better, he has been persuaded by the company to print the veriest nonsense in the hope that its publication will prolong the opportunity for the insiders to manipulate the stock and get completely rid of their holdings in advance of the annual meeting in April.

Electricity merely gave last week and the week before advance news of what will be public matter after the annual meeting. We shall continue to give such advance news. We have been for over two years three months in advance of all competitors in reporting the actual condition of this company's affairs.

The *Advertiser* accepts the statement as correct that the company has earned some money this year.

Yet the statement is flatly false.

A record of the transactions for the year would show that the treasury assets sold and old accounts collected amount to far more than the bonds retired and debts paid, and that the cash on hand has not increased since January 31, 1894.

In addition to this there was a loss during the year of over $2,000,000 by the drawing out of the Ft. Wayne Company, the loss of the feeder and main patent, the expiration of the incandescent lamp patent. Where are the profits ?

The astute financial writer chatters about the difference between receiving 4 per cent. on $100 of stock and 8 per cent. on $50 of stock very like an up-country farmer discussing the Government currency problem.

He does not seem to know that the capital is impaired, that the marking up of present assets to cover this impairment would land the men who tried it in the penitentiary, and that no dividend of any kind can be paid while this impairment continues even if the company were earning money, which they are not. He should consult the New York State statutes.

The stockholders of G. E. will get no dividends in this century or the next without a scaling down of the stock.

This scaling down is already decided upon, and we suppose the average New York and Boston daily paper financial editor will learn it after the event by reading his Schenectady, Amsterdam or Podunk exchanges.

What daily paper will gather to itself honor and credit by first presenting the true story of G. E., its present condition and future prospects?

The Electropoise.

A Defender of the Humbug.

To the Editor of Electricity.

Dear Sir: This letter was written some time ago, but when you ceased agitation of what you were pleased to call "Electro-Medical Fraud," I thought it best to drop the matter; but since you have began anew by copying an extract from a foreign prejudiced paper I consider it my duty to enter my protest against your indecent articles headed "Electro-Medical Fraud," which I hope you will have the fairness to publish.

I would not be guilty of replying to your vile and venal articles in the spirit and tone in which they were written, nor would it be gentlemanly for me to seek to say through your own publication that the attack you made on the Electropoise and the Electrolibration Company exposes your ignorance and shows a lack of information as well as a lack of intelligence on the subject you fain would discuss; nor would it be in good taste to call you a fool because you happen to be an editor; nor would it be courteous to say that as an apprentice journalist you were seeking notoriety as a scientific writer in a slander suit in which you were incapable of losing anything, and perchance increase the circulation of your publication; but I will say that, in my judgment, you have shamefully abused the privileges of a free press in attacking in a scandalous and libelous manner honorable men and criticizing a subject which you have not tried to comprehend.

I wish to say that I am in no way connected with the Electrolibration Company, nor does this letter emanate from any suggestion of the company; so that what I may say reflects no opinion of the Electropoise people, nor are they responsible in any measure or in any way for the opinions of this letter.

There was a time when I did not only disbelieve in the therapeutic properties of the Electropoise, but regarded it as the rankest humbug. I looked on the credentials and recommendations published by the company as so many acts in a farce to humbug the credulous and draw dollars from the pockets of sick and afflicted people who were willing to try almost anything to restore health. I saw it advertised in the leading magazines and weekly publications and especially in the *Litery* (sic) *Digest*, and every time I saw the advertisement it added more and more to my disgust for the Electropoise, and when in this disgusted condition, when I was prejudiced almost beyond the power of conviction, my attention was called to its wonderful powers by a warm personal friend, and one in whom I had the greatest confidence, a gentleman at the very top of his business in knowledge and capability, Mr. John W. Rhines.

Then follows a long eulogy of Mr. Rhines, a description of his case, a first-rate puff for Funk & Wagnall's new dictionary, a good advertisement for Mr. Rhines's patent voting machine and a description of another so-called cure—in all about enough of matter to fill two of these columns.

The letter then proceeds:

Now, Mr. Editor, the two cases above cited are two effects that you will not deny, or dispute, whatever may be the case, and it is for you now as a scientist to show the cause apart from Electrolibration, but these are two cases which you cannot answer, as you did, or rather as you tamely tried to answer, the Brooklyn correspondent, for science will not accept such an answer. Ridicule and reason are not synonymous terms, and while you may have thought buffoonery was the best method to dismiss a subject which seemed to you ridiculous, because ignorant and unwilling to be convinced of its therapeutic qualities, it shows plainly either the lack of a scientific mind, or a determination not to investigate. You, posing as a writer on scientific matters, should have been the last one to use ridicule and sarcasm for reason in answering a gentleman who was, in all sincerity, inviting you to investigate a subject on the side of which there is the greatest preponderance of evidence as to its healing merits, and which was of vital importance to the general public as well as the scientific world.

Now, sir, if you are writing in the interest of electricity endeavoring to lead men to a knowledge of the truth along the avenues of science, seeking to enlighten the masses in the hidden and unseen forces of Nature, take up those two cases, and prove to the individuals themselves and to the satisfaction of their friends that Electrolibration had nothing to do with their healing, or else back down and say that your articles were the production of immature reflection—but, remember, when you take up those two cases, you have staring you in the face two effects which by no process of reasoning you can deny, and every effect must have a cause. Respectfully yours,

Thos. M. Smith.

28 Chestnut Avenue, Jersey City, Jan. 4, 1895.

Our correspondent is evidently not accustomed to writing for publication, but in his evident honesty and sincerity his verbosity and faulty style can be forgiven and overlooked. We will also undertake to say a few words in reply, even though his methods of expression are not those best calculated to draw them forth.

In the first place, we have never attempted to discredit the honesty or genuineness of the testimonials given in behalf of the Electropoise. Honest testimonials of this kind, for quite as worthless agencies, are as old as history. Hoodoos and incantations, amulets and charms, faith-cures and mental healing, have been potent in all ages, and a belief in them has in the past been incorporated in all religions. The effect of such things upon patients is well understood by the medical profession, and resort is often had to bread pills and such like remedies, with results that would be surprising to one who did not understand the effects of purely mental agencies in combating disease. While confidence in the physician and in his remedies is often a most important factor in the success of a treatment, it is not always essential, for we see patients daily recovering where confidence is entirely lacking in both. They often recover in spite both of the remedies and of the doctor. When a patient recovers after a treatment with bread pills, or teaspoonful doses of pure water, it is useless to argue with him that the recovery is not due to the treatment. A reasonable man may be convinced when you tell him that he has been taking something that he *knows* could have no effect whatever, but there are some who will not believe even then. This state of mind is well illustrated by the story told of a patient suffering with monomania. He was perfectly sound and rational in all respects but one, and that was that he had the hallucination that he was dead. No argument could convince him that he was not dead, and finally in desperation his physician said: "Now you will admit, won't you, that a dead body can't bleed?" "Yes," replied the patient, "I will admit that a dead body will not bleed." "Very well," said the doctor, taking out his scalpel and making a slight incision in the patient's arm, and pointing triumphantly to the flowing blood, "that proves conclusively that you are not dead." "No it doesn't," quickly replied the patient, "it only proves that I was mistaken, and that a dead body *can* bleed."

We have no desire to convince Mr. Rhines, or any one else, that he is not cured. If he has recovered and is now well, we are glad of it, and it matters not to him or to us whether the recovery was preceded by a dose of bread pills or the Electropoise, but it does matter to suffering humanity whether those bread pills cost a fraction of a cent or $25.

If there be virtue in the Electropoise, then its virtues should be made known throughout the land, and Electricity should be crowned as a benefactor to mankind for having given specific directions how the instrument can be made at home at a cost not to exceed half a dollar. If it be good, then its manufacture should be encouraged for the benefit of suffering humanity, and there is nothing now to prevent its manufacture and sale by anybody. It claims to be protected by U. S. patent. We have shown that the Electropoise as made and sold is not made according to that patent, and that this claim is therefore fraudulent.

It is claimed that the Electropoise polarizes the body when applied. We have shown that it does not and cannot polarize the body as claimed, and that therefore this claim is a fraud.

It is claimed that this polarization causes a concentration of the atmospheric oxygen upon the polarized surfaces. We have shown that no polarization of any kind, however strong, causes such concentration of oxygen. This claim is therefore fraudulent.

It is claimed that this concentrated oxygen, acting upon the surfaces of the body renews and revivifies the blood, etc. We have shown, according to the best knowledge of the day, that concentrated oxygen can have no perceptible effects when thus applied. This claim, therefore, has no foundation in fact.

It is claimed that its benign influences are all primarily due to "thermo electricity by induction." We have shown that there is no such thing known to science as "thermo-electricity by induction," any more than there is a white that is black. This foundation claim is therefore a fraud.

It was claimed by Du Bois that the Smithsonian Institution had given them a typewritten letter certifying to the high scientific value of the discovery of the Electropoise. We have shown that the Smithsonian Institution never gave any such indorsement, and Du Bois now admits, we understand, that he has no such letter. This claim is therefore a fraud.

In fact, the whole business of the Electropoise is fraudulent, and we credit Du Bois and those with whom he is associated with too much sense not to know that it is fraudulent.

It is probable that many if not most of the proprietary medicines sold on the market are compounded after recognized formulas that have merit in certain classes of disease. So far as they are sold and used for these diseases they are legitimate. But the moment they are sold as cure-alls, to alleviate all the ills that flesh is heir to, that moment the business becomes a fraud and all those engaged in it guilty of abetting a fraud. No one questions the merit of Jenner's discovery of the efficacy of inoculation against smallpox, but if anyone prescribed vaccination as a remedy for cholera, scarlet fever and deafness he would be guilty of malpractice.

The Electropoise has the same merit as the buttons on one's coat—no more. But granting that it has genuine merit, it is an insult to the intelligence of the nineteenth century to offer it as a cure for such diverse diseases as aphonia, yellow fever and physical deformity. The Electrolibration Company, like human vultures, are preying upon the credulity of the poor, the sick and the unfortunate, and are waxing rich through their necessities. Unfortunately for our boasted civilization, a large portion of the religious press is abetting this fraud for gain and bringing scandal upon the church. Funk & Wagnall's *Literary Digest* is abetting this fraud. *Harper's*, *Scribner's*, the *Cosmopolitan*, the *Review of Reviews* are all prostituting their columns to the propagation of this imposture. These may seem like strong words, but the editors of those papers are not fools, and nobody but a fool would believe all the claims made for the Electropoise genuine.

A London journal says that since the introduction of electric light public performers are able to preserve their voices in better condition, and are 50 per cent. more often in good voice. They are cooler, do not perspire, and are not husky while singing or acting. The atmosphere is better and the equal temperature of the whole building has greatly diminished the risk of taking cold. Their throats are not parched and their voices not injured so much as in houses where gaslight is used.

Popular Electrical Science.

The Telephone—An Explanation of Its Modus Operandi—The Musical and Speaking Telephones and Their Essential Differences Described.

BY NELSON W. PERRY, E. M.

The telephone has been with us so long and come into such general use that we have ceased to marvel at its performances, and yet if we but consider for a moment the character of the service which it performs, and the extreme simplicity of the mechanism by which this service is rendered, we must stand in awe of this wonderful invention—wonderful not alone for the service it is able to render but also for the extreme simplicity by which extremely complex results are attained. The invention of the telephone, too, stands almost unique among inventions, in that it sprang into being almost full-fledged and complete. Almost all other important inventions in their perfected forms have been a growth, and have only reached their present perfection through many successive steps of improvement, to which many brains and hands have contributed. Not so with the telephone. The principles upon which the first instruments were made are rigorously adhered to in the best instruments of to-day, and although the modern instrument is better than that which was first given to the world, the improvement is due chiefly to better mechanical workmanship, a better knowledge of electro magnetic induction, and a better adaptation of the means to the desired ends.

The electrical transmission of simple sounds or musical notes was an accomplished fact long before the speaking telephone was known, and was accomplished in this way: If a diaphragm of iron were held before the poles of an electro-magnet, and the current turned on in the coils of the latter, it would attract the diaphragm to it and hold it in a concave position towards the magnet. If now the current were suddenly broken, the diaphragm no longer attracted because of the disappearance of the magnetism in the electro-magnet, would spring back, and this would give rise to an air impulse. If the making and breaking of the circuit were continued at regular and short intervals, these air impulses, due to the alternate attractions and flyings-back of the diaphragm, would follow each other with similar rapidity, and we would have at the further end a musical note of a given pitch. If the current with which we were operating were a strong one, so that the attraction and rebound of the diaphragm were strong, the note given out would be very loud. If the current used were a weak one, the note would be weak, but it would still remain the same note. If the interruption of the current were more rapid or slower, the effect would be simply to produce a higher or lower note; so that by varying the rapidity of the interruptions of the current, any note desired could be reproduced, and by using a stronger or weaker current these notes could be reproduced with greater or less intensity. Thus we had at hand before the discovery of the speaking telephone all the elements necessary for the electrical transmission of musical notes. But in the earlier musical telephones a vibrating diaphragm in front of an electro-magnet was not used. Page, an American, had discovered in 1837, that an iron bar when magnetized and demagnetized at short intervals emits a sound. This is due to the fact afterward discovered that an iron bar becomes slightly longer when magnetized, and resumes practically its original length again when demagnetized. The rapid changes of length due to magnetization and demagnetization, therefore, set up air vibrations just as would an iron diaphragm alternately attracted and recoiling, but since the changes in length of a bar under these conditions are exceedingly slight, the tone emitted is very faint. Those who have ever had their attention attracted to a transformer such as is used on alternating current lighting circuits, will have noticed a faint musical note emanating from it. This is due to the rapid changes of magnetism in the iron in the transformer, and is called after the discoverer's name, the Page effect. By the musical note thus given out we can tell exactly the number of alternations of current taking place on that circuit, for the transformer will give the same note exactly as a tuning fork, having the same number of vibrations per second as there are alternations of current in the circuit of the transformer.

Philip Reis, a German, by making use of the Page effect, constructed a musical telephone, the receiver of which consisted of a knitting needle, over which was wound a long coil of fine insulated wire. In order to magnify the sound, this was mounted upon a violin or other sounding box. The two ends of this coil were connected with a battery, and in order that the current might be interrupted in consonance with the sound waves to be transmitted, it was led through a transmitting instrument which was constructed as follows. He constructed a box over the top of which was stretched a membrane which would readily respond to sound waves. In the centre of this membrane was fastened a small metallic disk to which one of the circuit wires was led. An L-shaped piece of light metal rested at its two outer ends on the top of the box beyond the diaphragm, where they would not be subjected to the vibrations of the latter, while the third leg of the tripod, consisting of a small metallic point attached to the angle of the L, rested lightly in the center of the metallic disk where the vibration would be greatest. This L-shaped piece of metal was attached to the other end of the circuit wire, so that the current before reaching the knitting needle coils had to pass through the contact between the disk and the point. If now the membrane were set in vibration, as it would be by any sound in the vicinity of the instrument, it would cause the point to dance up and down on the disk, breaking the contact at each vibration, and thus alternately magnetize and demagnetize the knitting needle at the distant point for every sound wave that impinged upon the diaphragm. Thus the knitting needle, by reason of its alternating elongation and contraction would give out a similar note. Of course to make this instrument efficient it was necessary that the point and disk *should* break contact at every sound wave vibration, for if it failed to do so the knitting needle would not give out the same note. It would give out some other note, due to a less frequent vibration, and if this failure to break contact when it should occurred at irregular intervals, the reproduction would not be a musical note at all, but a noise. It speaks well for Reis's mechanical skill that his instrument did not fail of its proper functions; but, as we shall see in a future article, he has his excellent mechanical skill to blame for missing the discovery of the speaking telephone, for had his skill been less—had his instrument worked less perfectly—it would have been capable through accident of transmitting articulate speech, and as a matter of fact it is scarcely to be doubted that it did at times, through that perversity which often characterizes inanimate things, work so badly as to transmit spoken words. Reis called this instrument a "telephone," and very properly, for it was intended to and *did* transmit sounds to a distance. But it was not intended to transmit articulate speech, and could not when working as it was intended to work.

But words involve something more than sound. They may be, and often are, musical—that is to say, the musical tones may predominate and blend the one into the other. This is harmony, but it does not constitute speech. There is a certain *quality* in the human voice by which the voice of a friend is at once recognized; there is a peculiar modulation which is characteristic of the individual, and then above all is the articulation;—all of these must be reproduced if we are to transmit speech, and none of them are reproduced or capable of reproduction by a current that is alternately closed and broken. As on the ocean wave of large size there ride other smaller waves, and upon these still smaller ripples are superposed, so in the sound wave of the human voice—up on the fundamental wave, as it is called, which determines the loudness of the sound by the height of the wave, and the note by the frequency of these waves—it is to the small superposed wavelets upon this fundamental wave that are due the quality and characteristics of the voice. An interrupted current such as Reis used is totally inadequate to produce these small superposed waves, and therefore could not transmit speech. But Faraday, long before Reis's time, discovered that if a wire were vibrated in front of a magnet, electrical currents were generated in the magnet. It was the development of this discovery that led to the enormous dynamos of to-day, capable of giving out thousands of horse power on the one hand, and of the speaking telephone using infinitesimal currents by which whispers may be transmitted unblurred over hundreds of miles of wire. As a corollary to this discovery was the one that if a piece of iron is vibrated or moved in front of a magnet, the magnetism of the latter is disturbed; and still another, that if a coil of wire be wound around the end of a magnet, any disturbance of the magnetism of the latter would give rise to an electric current in that coil which would vary in strength as the amount of disturbance of the magnetism varied. It so happens that an iron diaphragm of circular section, which is supported at every point around its circumference but whose center is free to vibrate, is capable of taking up all air vibrations such as are produced by sound, even to the little superposed ripples which give character to peculiar sounds. Alexander Graham Bell conceived the idea that if such a diaphragm were placed in front of a magnet and caused to vibrate by the human voice, these very vibrations in all their minuteness and intricacy would be reproduced in the magnetism of the magnet before which the diaphragm was placed, and that if a coil of insulated wire were wound around the magnet, these magnetic disturbances would produce electrical currents in these coils which would correspond in frequency, intensity and all other respects with the sound waves which originally produced them. If this were so, then all that it would be necessary to do to transmit speech would be to carry these wires to the coil of another electro-magnet with a diaphragm in front of it. The oscillations in current in the coil of the first passing through the coil of the second would reproduce in it the exact magnetic disturbances of the first magnet, and these reproduced magnetic disturbances would set the second diaphragm into vibrations corresponding in every particular to the vibrations set up in the transmitting diaphragm by the words spoken to it, and the resulting sounds, except as to volume, would be perfect reproductions of the original ones. This is in fact Bell's method. It will be observed that the mechanism by which articulate speech is reproduced at a distant point is archaically simple and not easily disarranged—so simple in fact that any one may use it, and in fact any one with the slightest mechanical ingenuity can make it. Its make and use by unauthorized persons has, however, been prohibited for seventeen years by the U. S. patent laws. This prohibition has now ceased by the expiration of the full term of the patent, and the manufacture and use of the telephone is as free as the air we breathe. With the restrictions withdrawn, the telephone is likely to come into a vastly wider use than heretofore, and although one can now buy outright a set of instruments in the market at a very small fraction of the rentals formerly charged, there are doubtless many who would enjoy making a set for themselves. It is not to be supposed that much money can be saved by home manufacture, for the cost of making a single pair of instruments must be enormously greater than where they are turned out by the aid of machinery in large quantities, but the pride which one is apt to take in the use of instruments which are his own handiwork will doubtless impel many to undertake the task even though as great an expense is involved as in purchase. To assist those who would like to undertake the equipment of private lines, the next chapter or two will be devoted to instructions as to how to make the instruments at home and to install them, which it is thought will enable any one to equip his residence with instruments at small cost in a way to give entire satisfaction.

Peculiar Telephone Troubles Caused by Alternating Current Distribution.*

BY E. W. MIX.

The importance of the inductive influence of an alternating current distribution on telephone systems is well shown by some disturbances which developed at Odessa during last summer.

The telephone lines are all overhead, and the apparatus is of the American Bell telephone manufacture. The dynamos in the central station are of two types, one for 40 ~, and the other for 125 ~. The primary potentials of the circuits are 1,800 and 2,000 volts respectively. The 40 cycle machines alone had been used for the lighting of the municipal theater up to the time of the development of the disturbances. The secondary distribution of the theater was made at 60 volts, and the total energy consumption about 80 kilowatts. It had always been possible to detect a slight induction on the telephone lines passing near the theater when the 40-cycle dynamos were running, yet the influence was insignificant. When, however, the theater line was branched on the 125 cycle dynamos, the disturbances were quite important on certain lines running in the neighborhood of the theater.

It was at first thought that the source of the trouble would be found to be the induction produced by the overhead primary lines, but the telephone wires most influenced crossed these lines at right angles. The group of about twenty telephone wires most influenced passed from supports on the roof of one building to another about 20 meters high along the side of the theater, but about ten meters from the side walls, or fully 30 meters from the center of the theater, or, so to speak, center of gravity of the distribution. The distance between the telephone wires and the primary wires at the point where they cross is about seven meters. It being thought that the secondary circuits might alone be the cause of the troubles, a temporary load was made up for the secondary circuits in the transformer room by means of water rheostats. The load thus placed on the primary circuit was made even more than the normal; but, under these circumstances, all disturbances ceased to exist.

Investigation as to the arrangement of the secondaries led to the discovery that a great many circuits, and especially those for lighting the four galleries, were made on the loop system; i. e., where the current enters at one end of the circuit and leaves at the other, for the purpose of assuring an equal potential on all lamps in that circuit. In the gallery circuits, the current enters at one side of the theater and leaves at the other, so that the effect at a considerable distance from the circuit was the same as if a single conductor were placed around the gallery carrying a current equal to that of the circuit. This current was unusually large on account of the distribution being made at 60 volts only. These four circuits passing around the theater in this way produced a very strong magnetic field, the axis of which was practically coincident with the axis of the theater. This field embraced to a certain extent the group of telephone wires, and gave rise to the trouble.

In order to gain a more definite idea of the extent and distribution of the magnetic field so produced, an exploring coil was made up, consisting of about 100 meters of insulated wire wound up into a coil of about 1·20 meter in diameter, and the two terminals connected to a telephone receiver. By carrying this coil around inside and outside the theater, holding the receiver to the ear and turning the coil in different positions, it was very easy to determine the direction of the lines of force at any point, and the intensity of the noise in the telephone was a good measure of the strength of the field.

When all the circuits were on, the effect was very noticeable on the iron roof of the theater at a level a little above the group of telephone wires. On the ground outside the theater and immediately under the wires, the influence was also well marked. It is very likely that the iron roof added to the effects on the telephone wires in concentrating the lines of force which escaped from the edges of the roof and cut the wires near by. The iron roof acts somewhat as a pole piece to the magnetic field.

The same trouble developed at about the same time in another theater where the wiring of the gallery circuits had been made on the same loop system. Here it was easy to locate the trouble because the circuits were more distinctly separated. The influence was only exerted on two telephone wires which passed over the roof of the building. The instant these loop circuits were switched on, the noise in the telephone was noted. The intensity of the noise in each case had no relation to the load on any other than the loop circuits, so that it was plainly demonstrated that these circuits were the cause of the trouble in both theaters. The remedy in such cases is naturally the suppression of the loop system, and especially in cases where high frequency alternating currents are employed.

The importance of electrostatic induction effects on telephone lines was forcibly brought out by a condition which existed one day, and which was conclusively proven by experiments afterwards. It was found that a new disturbance was set up in a part of the city heretofore unaffected. Here there was a new branch of the primary line installed running parallel to a group of telephone lines for a distance of about 350 meters. The primary wires were on wooden poles about 7 meters from the ground, and the telephone wires also on wooden poles about 11 meters from the ground, but on the opposite side of the street, the distance between the two lines being at least 20 meters. There were as yet no transformers branched on this line. The effect was first noticed on a line which ran but about 30 meters parallel to the primary lines and then crossed them at right angles. It was supposed that both primary wires were connected to the line circuit, but investigation showed that one had been by an oversight left disconnected. When the connection was established the disturbance ceased. Here the effect was purely electrostatic. The insulation of the primary line was perfect, so that the disturbances could not be attributed to any leakage to ground.

To more fully determine the extent of the electrostatic influence, the experiment was tried of connecting one pole of the dynamo to a circuit leading out in one direction from the station and connecting the other pole to a circuit leading out in the opposite direction. By this combination no current was sent out on any of the lines, except that necessary to give them an electrostatic charge. The disturbance set up in almost all the telephone lines of the city was such as to almost completely prevent communication. So long as only one circuit was so connected to but one pole of the dynamo, the influence was just sufficient to enable one to determine that the dynamos were running; but, on connecting the two circuits as described above, immediately the disturbances were set up. The insulation of the lines with the transformers connected was in the neighborhood of 300,000 ohms. The length of double line of one circuit was about eight kilometers and that of the other five kilometers. No current could be detected flowing out on these lines by means of the amperemeters, which were fairly sensitive instruments, and where one ampere could have been quite easily noticed.

The conclusions are, therefore, that electrostatic induction is quite as, if not more, capable of creating telephonic disturbances as electromagnetic induction with high frequencies and potentials, and precautions should be taken to keep the two conductors near together, so that one may neutralize the other. In electrostatic induction the earth, and even buildings, serving as an intermediary conductor of large capacity, tend to increase the area of influence of the electric charges received by the primary wires.

A Helmholtz Commemoration.

On the 14th ult., a festival in memory of Prof. von Helmholtz took place in the rooms of the Berlin Singakademie in presence of the Emperor and Empress and the Empress Frederick, the festival being under the auspices of the scientific societies with headquarters in the German capital. The hall was tastefully decorated, a prominence being given to a fine bust of Helmholtz. The ceremony was opened with a song composed by von Schütz. Dr. Von Bezold then delivered an oration recalling the services rendered to science by the deceased. He warmly praised Helmholtz's personal qualities; although from the very first signalled out as one of the leading spirits of the age, and in spite of half a century of flattering testimonies from the entire scientific world, he ever remained free from pride, and that has enabled us to contemplate his picture without a single afterthought. Herr Joachim then gave Schumann's "Abendlied" on the violin, and Brahms's "Gedenksprüchen" for eight voices terminated the sad celebration. The Emperor William has contributed 10,000 marks to the fund for the erection of a monument to Helmholtz in the chestnut grove behind the Berlin University.

Another Self-Propelled Vehicle Competition.

Another competition for mechanically-propelled vehicles is mooted, and again Paris is the center at which it is proposed to hold the trials. The tests will be made for highest speed maintained for long periods of time. The minimum distance for the runs has been fixed at 620 miles. Paris will be the starting point and also the winning post. Vehicles operated by electricity, steam or oil are eligible. The trials are arranged to take place next summer.

THE UTILIZATION OF OZONE.[*]

A Paper of interest, by Dr. O. Frölich, on the utilization of ozone, has recently been published in the Proceedings of the German Electro-Chemical Society. The statements which it contains are based upon observations made on a working scale in many cases, and refer in some instances to applications which are in actual operation. Certain of the methods of utilization put forward are admittedly only suggestions, but they are in all cases of a practical kind and worthy of attention. The apparatus used was one designed by Siemens & Halske, and is in principle identical with the Siemens ozone tube—now a classical laboratory instrument. A useful modification in detail consists in the substitution of mica for glass as a dielectric. Each unit of the apparatus is, therefore, composed of a metal tube with a mica sheath, enveloped in a mica tube with a metal sheath, the annular space between the two mica surfaces serving as a channel for the gas to be ozonized. The well-known modification of the Siemens tube, differing therefrom in that the coatings of the dielectric are water or dilute acid, is also useful, especially for small installations. It has the advantage of being transparent, and thus allowing the observation of the character of the discharge taking place between its opposing surfaces.

The two essentials for the successful formation of ozone are the use of an alternating current of high voltage and the production of a "silent" discharge. In modern practice the induction coil which has sufficed for laboratory experiments is replaced by a step-up transformer. It is not a matter of indifference in what manner the alternations occur. Should the curves representing the rise and fall of the current be unsuitable, a reduction in the output of ozone per unit of electrical energy is to be expected. The author states that the form of alternation found by experience to be most efficient has now been ascertained, but gives no details of the construction of the transformers designed for this particular end. When the right character of alternation has been arrived at the working of an ozonizing plant is simple, fair regularity of running being the chief requisite. The only measurement needed is that of the voltage at each ozonizer, which should be tolerably constant. It is noticeable that with an increased production of ozone a rise in the temperature of the ozonizers takes place, this being sufficiently great to need the circulation of water through the inner tube of the ozonizer. The uses to which ozone can be put may be conveniently dealt with under the following heads:

Chemical Processes.—Ozone, when used on account of its chemical activity, varies greatly in its effects according as it is used alone or in conjunction with other substances, e. g., chlorine. When ozone is blown through spirits of turpentine copious white fumes are evolved, the composition of which is at present unknown. The substance thus produced has strong bleaching properties, textile materials dipped in spirits of turpentine and then exposed to ozone being readily decolorized. A similar effect is produced when ammonia is substituted for turpentine, ammonium nitrite being a product. A considerable obstacle to the wide utilization of ozone is its comparatively high cost. Up to the present only 20 grammes of ozone per horse-power can be prepared, while 70 grammes of electrolytic oxygen can be obtained by the same expenditure. It follows, therefore, that the remunerative employment of ozone must be confined to cases where action upon the whole bulk of the material treated is not contemplated, but merely a removal of impurities, or improvement in quality of a tolerably high-priced commodity is aimed at.

Sterilization.—Ozone acts rapidly upon micro-organisms, and a special investigation has been made by Dr. Ohlmüller to ascertain how far this action can be utilized. The chief conclusion arrived at is that when oxidizable matter as well as bacilli is present in the liquid to be treated, the former is attacked first and the latter are killed only after this initial oxidation. The destruction of the bacilli when once begun is rapid, pathogenic organisms being killed almost instantaneously. It appears, therefore, that the use of ozone for sterilizing water is only advantageous when the water is fairly pure and free from much oxidizable organic matter. The author suggests that the town supply in Berlin, which is nearly free from organic matter, should be ozonized before being sent into the mains.

Ventilation.—The action of ozone upon micro-organisms on the walls and in the air of living rooms is not great; moreover, the smell of pure ozone—as distinct from the products associated with hydrogen peroxide, which characterize the air of pine forests, and are vulgarly termed "ozone"—is unpleasant, and if the gas be present in notable amount it has a strongly irritating action on the throat and lungs, resembling chlorine in this respect. It follows that any utilization of ozone for furthering ventilation must depend upon the conjoint use of substances—e. g., ethereal oils, capable of modifying the effects of the pure gas.

Improving Articles of Consumption.—The effect of ozone upon spirits has long been known to resemble that which results on keeping. Apparatus has been devised for treating the contents of casks in a cellar or store individually. It has been found that the improvement is more marked with strong, sweet wines, spirits and liqueurs, than with alcohol liquids light or acid in character. The ozonizing is best applied moderately but repeatedly. The method has been in use by one cognac maker for several years, good results having been obtained. The flavor of tobacco and coffee is also improved by ozonizing. A crucial test of this alteration has been afforded by the action of ozone upon the so-called "stink-beans" sometimes found in coffee. These are isolated beans, which, during storage and transport, have suffered a fermentative change sufficient to cause them to contaminate the whole consignment with their own offensive taste and smell. One circumstance constitutes a drawback to the treatment of coffee with ozone, viz., that the broker has a strong prejudice in favor of a particular gloss and color, which properties are deteriorated by ozonizing, although the flavor is improved.

The applications about to be described have either actually been found of technical value, or are fairly certain of being adopted commercially. René, a piano maker of Stettin, has used ozone since 1881 to remove the resonant properties of the wood used in making the instruments which he constructs. The wood is placed in a warm, well-closed chamber, and ozonized air is passed through for 12–24 hours. The wood is thus uniformly hardened and made less sensitive to fluctuations of temperature; the alteration is probably due to the oxidation of the resin contained in the wood.

The customary method of oxidizing linseed oil for the manufacture of linoleum, by hanging strips of fabric (termed "scrim") saturated with the oil in an airy loft, occupies several months. By the use of ozone the oxidation is completed in a few days.

The author, in conjunction with Herr Keferstein, a bleacher having a factory at Griffenberg, has worked out the details of the application of ozone to the bleaching of linen, with the result that grass bleaching is now given up. The ozone installation has been running for a year. Its capacity is 500 kilogrammes of linen per day. It is impracticable to use the ozone per se, both on account of its high cost and its excessive "tendering" action on the fiber. The linen is therefore subjected to the usual preliminary treatment with acid, alkali and chloride of lime, precisely as is often done in the case of grass-bleaching, the only point of distinction being the substitution of the ozone bleaching for the last-named stage of the process. Favorable results were also obtained by steeping the linen, previous to exposure to ozone, in weak solutions of hydrochloric acid, spirits of turpentine and ammonia. The treatment with ozone is carried out in a closed chamber, and continued for six to seven hours, whereby the decolorization is carried to about three-quarters the extent ultimately reached. The completion of the process is effected by alternate treatments with ozone and chloride of lime. The saving of time and the independence of weather attained by the use of ozone are the chief advantages of the system.

Bleaching by ozone can also be applied to beeswax, which is still sometimes sun-bleached. A whole series of starch products have also been prepared with the aid of ozone, the work having been carried out by the author in association with Herr Hellfrisch. The usual methods for preparing such substances as soluble starch, dextrin, etc., from raw starch, often yield products of dark color and bad smell, which diminish their commercial value. The bleaching action of ozone in conjunction with chlorine is found to give materials of this kind a lighter color and better odor and flavor.

[*] "The Electrician" (London).

The Inventiveness of Outsiders.

It is remarkable, says the *Iron and Coal Trades Review*, how very many of the greatest inventions and discoveries of modern times have been achieved by men who were not themselves trained to the business or profession in which they acquired distinction. Neither Bessemer nor Siemens was trained as a metallurgist, and yet they have been acclaimed as the most epoch-making inventors in the history of the iron trade. Sir William Armstrong was not trained as an engineer, but as a solicitor, and yet he has revolutionized the art of gunnery and the manufacture of hydraulics. And so with many other modern instances. The so called practical men are too often incapable of looking all round a subject, and are so wedded to usages and established rules as to look with serious disfavor upon any really novel ideas however meritorious.

One of the most useful and ingeniously contrived electrical inventions of to-day is an electric fire alarm system which received the highest award at the World's Columbian Exposition, and it is an interesting fact, says the Rockland (Me.) *Courier-Gazette*, "that this wonderful apparatus was invented in Rockland by L. H. Des Isles. Mr. Des Isles, who is a native of Lamoine, came to Rockland to attend the Commercial College, and afterward obtained a position in the engine room of the steamer Mt. Desert. After several seasons on the Mt. Desert he accepted the position of engineer on the tug Frederick L. Wilson, and while on this boat he originated an electric heat alarm, which was the basis of the system now in use. A hot journal, which required almost constant attention, was a great deal of trouble to Mr. Des Isles, and in order to overcome this he arranged an electrical contrivance which rang an alarm when the bearing became overheated. From this small beginning the present system was perfected. Mr. Des Isles is now foreman of the company's works and is a large stockholder in the concern."

EXPERIMENTS IN CABLE SIGNALING.*

BY PATRICK B. DELANY.

Within the past few months I have made some experiments in signaling over the Direct United States cable and the cables of the Anglo-American Company, the results of which may be of interest. The trials were mainly with a specially designed system of automatic transmission. Over the direct cable—Ballinskelligs, Ireland, to Halifax—the entire traffic was transmitted for three weeks under very unfavorable conditions, owing to the almost unprecedentedly severe electric disturbances which prevailed at the time (February last); but the trials demonstrated very clearly, nevertheless, the great superiority of machine working over hand transmission.

In order to get at exact results, on February 27, during the busiest part of the day, 274 messages sent consecutively were carefully timed, showing the following speeds:

Number of messages.	Letters per minute.	Number of messages.	Letters per minute.
3	88	32	85
22	91	16	88
12	95	30	87
10	86	29	88
2	91	26	87
4	84	—	
88	87	274	

Average, 88 letters per minute approximately.

On the morning of March 2, when the cable was comparatively clear of earth currents, 84 messages were transmitted consecutively as follows:

Number of messages.	Letters per minute.
7	100
5	98
17	95
5	89

Average speed 95½ letters per minute, and without an "R. Q."

The foregoing results were with *regular traffic*, code messages, and under duplex conditions of cable.

Experimentally, code messages sent at 103 letters per minute were repeated back promptly from the recorder slip, while newspaper matter transmitted at speeds ranging from 110 to 120 letters per minute was readily repeated back correctly. I specify two instances of official and careful timing.

February 14: 268 letters from a newspaper paragraph, comprising figures and fractions of stock market reports, were transmitted at the speed of 111 letters per minute, and immediately repeated back from the strip at Halifax without an error.

On February 14, 190 letters were transmitted at the rate of 120 letters per minute, and repeated back promptly and correctly with exception of one word of two letters.

While speeds with actual traffic are the real tests of both cables and systems, it is but fair to assume that these experimental speeds would soon be reached with regular traffic, for experience has proven that after a few months' familiarity with automatic signals, operators read them at a speed 20 per cent. above the speed considered safe at the beginning.

During the month of September experiments were made with the same system over the four cables of the Anglo-American Company—Valentia, Ireland, to Halifax:

Highest Speed of Regular Traffic.

	Letters per minute.
1873 cable	153
1874 "	158
1880 "	133
1894 "	249

These figures require some explanation, however. Instead of translating signals into manuscript the Anglo-American Company cuts the recorder slip into short sections and pastes them on a blank, so that repunching or retransmission by key is done directly from the received record. In order to facilitate this cutting, *three* spaces are made between words in the punching. In arriving at the foregoing results two extra spaces are allowed for every word of five letters, which is the average for ordinary telegrams, and these extra spaces were computed on the basis of 3.7 impulses to the letter, which is the average shown by the analysis of 10,000 words made a few years ago in France. As a matter of fact, however, *cable* words average about *seven* letters to the word; therefore, extra spaces should be reckoned accordingly. This would modify the foregoing figures as follows:

	Letters per minute.
1878 cable	149
1874 "	149
1880 "	129
1894 "	248

which was the *actual* speed of transmission with regular traffic code messages, carefully timed by officials of the company at the station.

It is customary to reckon speeds by counting revolutions of the wheel of the transmitter—in which case, of course, all spaces are included; but, unless a stop watch in experienced hands is employed, the count is apt to be inaccurate. A count of the actual letters transmitted during a trial of several hours leaves no room for doubt as to exact results, and as re-transmission from the received strip requires signals which may be read by the average operator without studying, absence of complaint from the receiving station is the best evidence of their legibility. During these experiments at Valentia all signals were judged by the "good for traffic" standard, and the strictness with which this rule was followed was proven by the fact that, except in the case of the '80 cable, none of the speeds reached with regular traffic were exceeded in the experimental transmissions. On several occasions 141 letters per minute, over '80 cable, were reported "good for traffic," and 146 "fair for traffic"; but after a lapse of a day or two, when traffic was carried, the speed did not rise above 129 letters. The decline might easily be attributed to some change in the adjustments at the receiving station.

Working from London to Heart's Content Direct.

An experiment was made with a repeating system arranged by the writer which, judging from the results obtained, foreshadows, it is believed, important changes in cable working in the near future.

Regular traffic was punched in London and transmitted direct to Heart's Content over the '94 cable as follows:

September 25—Twenty-four messages regular traffic, speed 178 letters per minute.

September 26—Fourteen messages regular traffic, speed 160 letters per minute. No "R.Q's."

These experiments were hurriedly prepared, but were sufficient to show beyond a shadow of doubt that transmission may be effected from long land lines into ocean cables at the same speed as the cables are worked from their landing places. London may transmit to Heart's Content and New York may send direct to Valentia, thus saving repunching, retransmission and considerable time. So far as transmission is concerned cables may, in effect, be thus extended directly to the great inland centers where the bulk of the cable traffic originates, and this, too, without any of the dangerous drawbacks of bad coasts, shore ends, etc., and without any sacrifice in speed by the practical extension.

Working by Sounder Across the Atlantic.

For several years the writer has been engaged in devising a system for working long cables by key and sounder, and hoped for a successful demonstration while at Valentia; but, unfortunately, the key-controlled transmitting apparatus sent from London to Heart's Content failed to arrive in time. With an ordinary Morse key at Heart's Content, however, and a special receiving relay at Valentia, on September 30 Valentia received over the '94 cable on an ordinary Morse sounder 66 letters per minute, and these were automatically repeated to London, who pronounced the signals good. With the special transmitter designed for the experiment I think a speed of 100 letters per minute would have been reached, and I am quite satisfied that this speed can be accomplished between New York and London through automatic repeaters. I am strongly of the opinion, however, that in the near future all long cables will be operated by the automatic machine system of transmission.

Prize for an Improved Incandescent Lamp.

The French Societe Technique offers the following prizes to persons of any nationality: £409 for a markedly better incandescent gas lamp, to be sent in before April 1, 1895, the council to decide whether the time may not be extended to May 1, 1896; £320 in various prizes for essays on any subjects affecting the gas industry, particularly on mechanical handling of coal, coke, etc., on water, gas or revivification, or on the substitution of hydrocarbons for cannel; £80 between those who have made the greatest progress in apparatus for making or using gas. Papers to be in French, and unpublished; motto, with name in envelope, and a declaration inside that the paper is unpublished, and that the author will not publish otherwise for a year. To be sent to the Societe, 65 Rue Provence, Paris, by the end of April next. Also prizes of £10 to the authors of the best papers at the annual meeting, provided in this case that they are members of the Societe; and the usual prizes of £8 each to deserving workmen long under the same company, or in the same gasworks, without a break.

The Magnetic Properties of Iridium.

In a Paper communicated to the *Physical Review*, Mr. S. H. Brackett gives an account of some experiments he has made of the magnetic properties of iridium. The samples used contained 98 per cent. iridium, with some platinum, and a trace of phosphorous, but no iron. A bar of the metal 13·3 mm. long, 3·2 mm. wide, and 0·9 mm. thick, when brought into the field of an electro-magnet, set itself at right angles to the lines of force and became permanently magnetized in a transverse direction, and when suspended freely set itself east and west. The permeability of a larger bar was tested and was found to be unity, and, although the specimen was sharply struck while in the magnetizing coil, no induced magnetization was produced.

The Intrinsic Brilliancy of Artificial Lights.

According to the *Gas World* the intrinsic brilliancy per unit of area of the filament of an incandescent lamp is 133 times greater than that of the gaseous rival which has appropriated the first half of its name. It seems probable that in this estimate the meshes of the gauze in the latter lamp have been taken as if solid.

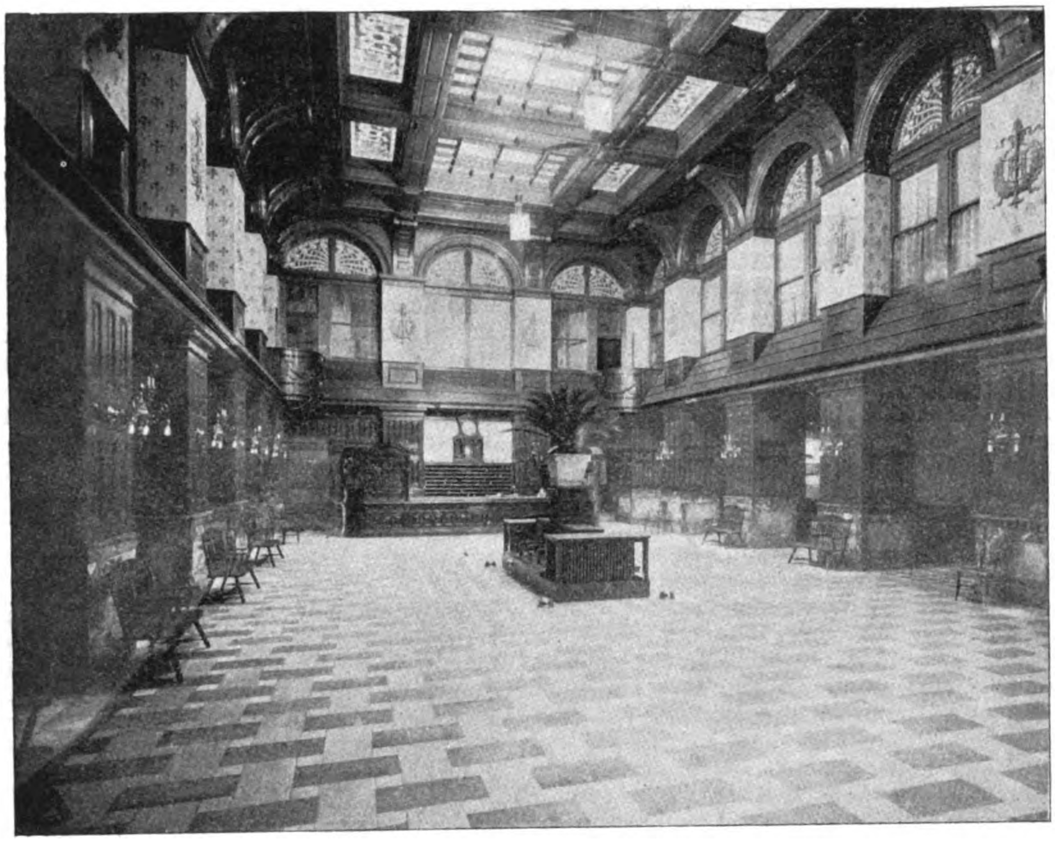
Mr. G. W. C. Lomb, of Alabama, an electrical engineer and inventor, seems to be about as prolific in the production of electrical devices as the inventor of the kinetograph himself. Among Mr. Lomb's latest inventions are the electric fire engine, complete system for the propulsion of canal boats by electricity, complete overhead system of street railroads, new and novel electric lamp, electric fire kindler, new steamboat wheel, marine and steamboat condenser, safety compensating trolley for electric railroads, electric return circuit for street railroads, complete surface trolley system for the same, and an underground system for street railroads. Mr. Lomb, we are sorry to learn, was at last accounts, sick in Cincinnati with acute indigestion.

THE CLEVELAND CONVENTION.

Mr. George F. Porter, secretary of the N. E. L. A., has issued the following bulletin :

The indications are that the attendance at the Cleveland meeting will be very large, and a number of the delegates intend taking their wives.

Hotel accommodations should be secured early to insure comfortable quarters. The headquarters will be at the Hollenden Hotel, the rates being : American plan, $3 to $5 per day; European plan, $1 to $3 per day. Other hotels in close proximity to the Hollenden are the Weddell, $3 to $5 per day; the Stillman, $3 to $5 per day; Forest City, $2 to $3 per day; Kennard, $2 to $3 per day; American, $2 per day.



THE HOLLENDEN.

The Hollenden Hotel, the headquarters of the Association, is one of the best appointed hotels in the country. The service can scarcely be excelled, the rooms are large and well furnished, and the lobby is roomy and well fitted for Convention purposes. Mr. Frank Probst, the manager, is a hotel man of wide experience, and the proprietor, Congressman Holden, is also on hand a great deal of the time looking after the interests of the house.

Those who attended the Railway Convention in 1892 at Cleveland do not need to be told that they will have an enjoyable week there in 1895.

A writer in the N. Y. *Sun* states that passengers riding on the electric railway between West Farms and Mount Vernon have the privilege of listening to an acoustic manifestation that in a remarkable manner illustrates some of the earlier experiments in developing the telephone. The track is a single one and the potential of the current is high; its amperage is also considerable. As a result, when a car is waiting on a switch for one coming in an opposite direction, the approach of the latter is audible at the distance of a mile to the passengers in the waiting car. The sound vibrations are carried along the wire, through the trolley, to the wooden roof of the car. This acts as a diaphragm, which faithfully reproduces the rumble of the approaching car. A mile away the noise of the wheels is distinctly audible, and at the distance of 1.000 feet the sound becomes a loud roar. Outside the car, however, practically nothing is heard until the moving car is within a few hundred feet of the switch.

TORONTO BRIBERY MATTERS.

How Motors were Sold in 1891-2.

(From Judge MacDougall's Official Report to the Mayor.)

In September, 1891, very important questions began to be discussed in the Council as to the kind of electric motive power which should be adopted by the new contractors; some were in favor of the trolley or overhead system. The Edison General Electric Company, a very wealthy electric manufacturing company, were anxious that the trolley system should be adopted, as they thought that in that event they might secure from the Kiely-Everett people the contract for supplying the motors for their cars. Early in September they made inquiries from a Mr. Johnson as to the name of an alderman who might be of use to them in promoting the adoption of the trolley system, and also who might have local influence with the Kiely-Everett people. Johnson introduced Alderman Hewitt to the Edison manager, Barr. Hewitt intimated that if Barr could secure Alderman Hall's support, too, he thought Alderman Hall and himself not only could assist in securing the adoption of the trolley system by the Council, but they could also ensure the Edison people getting the contract from Kiely, Everett & Co. for supplying the motors necessary to equip their rolling stock. Hewitt introduced Barr to Hall, and suggested that as Hall was a lawyer the best and safest way to secure his support was to give him a handsome retainer. Barr accordingly arranged with Hall to pay him $1,000 as a retainer. Hall had never acted for the Edison Company as solicitor; never did any legal work for them before or after the retainer; the payment was made on the 22d September, 1891. A little later in the year Hewitt intimated that in order to make certain that he and Hall would exert themselves actively in the direction required by the Edison Company, it would be necessary to have an understanding with the Edison Company as to a commission to be paid them (Hewitt and Hall) in the event of the Edison Company getting the contract for supplying motors to Kiely, Everett & Co. Barr swears that an arrangement was finally made with Hall and Hewitt to the effect that they were to be allowed a commission equal to the amount which the contract price, when awarded, should be in excess of $2,100 per car. It was thought, looking to the then current prices for car equipment, that a reasonable rate to be expected would be $2,300 or $2,400 per car; it was understood that the company would require about 200 cars fitted out: so that this commission, it was estimated, would amount to between $40,000 and $50,000. The next thing that happened was that Barr began to have doubts as to Hewitt and Hall having any influence with Mr. Everett. Johnson swears that after a consultation with Barr he was instructed to tell, and did tell, Hall to telegraph Everett and bring him here from Cleveland to have an interview with John Muir, the manager of the Edison Company, who came from New York for the purpose, and if he were able to accomplish this he would in some measure demonstrate the fact that he possessed influence with Everett. This was done. Everett came here, and an interview was held between Muir, Everett, Hewitt and Hall in Hall's office. Notwithstanding this supposed proof of the existence of influence, the Edison Company still declined to advance more money until the contract was actually secured. At the municipal election of 1892 Hall and Hewitt were both defeated, but they nevertheless continued to urge to Barr that they still possessed as much influence out of the Council as in it. They finally agreed after much negotiation that if they got a cash advance of $4,000 they would abandon their claim to the contemplated commission, and enter into a fresh written agreement or contract for their services and influence. On the 6th day of February the document was duly signed and delivered, and the $4,000 paid over to Hall and Hewitt. The agreement is here transcribed, that it may not appear that I have attached undue importance to the character of the document, or to its incriminating nature :

"In consideration of Messrs. Hall and Hewitt obtaining for the Edison Company's tender, should they make one to the Toronto street railway syndicates, the preference and acceptance (all things being equal in equipment and price), we, the said Edison Company, hereby advance to them as commission the sum of $4,000. Should the said Hewitt and Hall not obtain the preference and acceptance for such tender of the Edison Company, such sum to be returned by the said Hall and Hewitt in equal shares. After the first tenders are opened we undertake to give the figures of all the tenders lower than the Edison Company's tender to Mr. Barr before the acceptance of any tender; and that an opportunity will be given, if necessary, to Mr. Barr to make another tender on behalf of the Edison Company.

"We further agree not to advocate any system save the Edison system in Toronto at any time.

"Dated at Toronto, this 6th day of February, 1892.

"WILLIAM M. HALL.
"EDWARD HEWITT.
"M. D. BARR.

"Witness, A. T. JOHNSON."

The Edison Company subsequently got the contract from the Kiely-Everett syndicate, and, Barr says, made an enormous profit out of the same. Hall says that he only got part of the $1,000 (ostensibly paid as a retainer) and that Hewitt got the rest.

Upon this evidence and the admissions of Hall, I find that William and Edward Hewitt, who were aldermen in 1891, corruptly received the sum of $1,000 from the Edison Electric Company to improperly influence them as aldermen and to induce them to support in the City Council a resolution for the adoption of the trolley system of applying electricity in the street car rolling stock. And that after they had ceased to be aldermen, in February, 1892, they received the further sum of $4,000 in cash in lieu of and in substitution of a previous corrupt bargain and agreement which they had made with the Edison Company while they were aldermen of the city of Toronto, whereby they were to receive a large commission for procuring a contract for the Edison Company with the Kiely-Everett syndicate, which commission, it was agreed, was to be payable upon the contingency of their inducing the City Council to adopt the trolley system.

Some light is thrown on the number of visitors to Niagara Falls by the returns of the electric road running along the Canadian bank from Queenstown to Chippewa, through Victoria Park. It appears that the travel for the season up to November reached about 467,000 passengers. This road skirts the river all the way within a few feet of the edge of the bluff, and is operated by the water power of the Horse Shoe Fall, the generators being driven by turbines which receive water through a canal just above the fall and discharge under the veil of tumbling foam and spray. The plant is of 3,000 H. P. It was the first large utilization of the energy of Niagara, and it is now proposed to parallel the road with another on the American shore, which shall have the peculiar attractiveness of running out on brackets at the foot of the cliff, and will thus put the tourist right over the boiling waves of the Whirlpool Rapids.

BOOK REVIEW.

Central Station Bookkeeping and Suggested Forms, with an Appendix for Street Railways. By Horatio A. Foster, Mem. Am. Inst. E. E. Cloth, 8vo. 139 pp. Price, $2.75. New York: The W. J. Johnston Company, Limited.

It is seldom that an author brings to his subject such well developed and mature faculties, both natural and acquired, as Mr. Foster has to this subject of central station bookkeeping.

Mr. Foster has a natural mental bent toward statistics which he has cultivated to a further degree. With this he has combined a wide experience as an electrical expert, and the United States Government was glad to avail itself of his services in collecting and arranging electrical statistics for the United States Census Report, and the fulness of those portions which Mr. Foster had immediately in charge has fully justified the selection.

In this way the author has had unusual opportunities of familiarizing himself with the methods of accounts most in vogue in electrical supply stations, and being himself an expert accountant has brought a ripe judgment to bear in sifting that which was good and adequate from that which in the light of present development can be regarded as little better than mere makeshift. To this he has added many suggestions of his own which every business man will recognize as additions in the right direction.

In making these additions he has happily avoided anything of purely tentative value and has not departed in any case, so far as we have been able to detect, from the recognized lines of sound bookkeeping and business policy. He has thus given us suggestions, with forms and diagrams, for the organization of the staff of electrical central stations, the classification of accounts and reports, which will enable the management to determine at any moment, with the least expenditure of energy, the condition of business, and particularly the unit cost of generation and distribution of current. Of these forms and diagrams there are seventy-five in all, and many of them are of full size so as to form exact models for the getting up of a set of books. Recognizing the fact that all stations are not alike nor operated under identical conditions, and that no one set of books can meet equally well all conditions, alternative methods are suggested as types from which books to meet special requirements may be gotten up, and doubtless the author would be willing to give his personal assistance in special cases to designing of systems to meet unusual requirements.

In an appendix is furnished a classification of accounts of electric street railways, together with instructions, forms of books, etc., necessary to carry it out.

In the electrical supply business this question of proper bookkeeping, whereby accurate and reliable data concerning the business should be rendered available, has to a very large extent been a desideratum that has remained unsatisfied. This has been rendered conspicuously evident whenever the attempt has been made to collect data. The meagerness of the information attainable has been due more often to the fact that the managers of stations did not possess it themselves than to any unwillingness on their part to be accommodating. The consequence has been that we do not know to day what may be regarded as average practice in this country. No one appreciates this more than the manager himself, for he would not only like to know what he himself is doing but also how his work compares with that of others in the same line. We regard any effort to change the situation for the better, as a distinct gain to both the public at large and to the manager, and feel sure that this very intelligent attempt on the part of Mr. Foster will meet the hearty commendation that it so richly deserves.

Northwestern Electrical Association.

The third annual meeting of the Northwestern Electrical Association occurs at the Hotel Pfister, Milwaukee, this week. This young organization has had a phenomenal growth since its inception and is continually gaining in strength. At the last meeting in St. Paul there were over 100 members present. An interesting and profitable programme has been prepared and practical subjects will be discussed by thoroughgoing men.

F. P. Little.

Mr. F. P. Little, the leading member of the Electrical Construction and Supply Company in Buffalo bearing his name, died a few days ago, after an illness of several weeks.

Mr. Little was one of the leading men in the profession in his city and well known throughout the East. He was a splendid companion, a whole-souled, genial man, and will be sadly missed by a wide circle of friends.

Personal.

Mr. W. D. Packard, of the Packard Electric Company, Warren, O., was in New York for a few days last week. He reports his company as in excellent condition and looking for big business as soon as the Supreme Court clears up the lamp situation finally.

Mr. Frank Parsons has resigned from the Davidson Fan Motor Co., of Boston. He will continue in the electrical line, in which he has made rapid headway toward the front.

Mr. Charles D. Shain's poetic New Year's greeting to his friends has created considerable comment, all of a favorable nature. It is said that he contemplates retiring from active business and devoting his attention to verse.

Mr. A. T. Moore, Jr., will open an office in Buffalo next week. He will have control of Walker apparatus in that territory and will also handle several other lines.

Col. S. G. Booker, of St. Louis, is expected in New York in a few days. He reports the Phœnix Carbon Company as in good condition, fully equipped, and very well satisfied up to date.

An International Exhibition of Patents and Inventions.

There has been announced an exhibit with the above official title, to be held at the Grand Central Palace in this city during the month of March.

The prospectus is before us, containing a long list of names of eminent gentlemen said to be connected with the enterprise. Notwithstanding these names, however, this prospectus is not calculated to create any high expectations for the Exhibition. The English language is maltreated in the first sentence, and in nearly every other sentence. It is stated that "the Exhibition will be divided in three departments: (1) Patents, (2) Patent Medicines, (3) Photographs, Photographers' Apparatus and Supplies."

Rather a strange combination. What have patents to do with patent medicines? The promoters tell us:

> (2) The second department of this Exhibition will be devoted to the Exhibit of Patent Medicines. Possessors or Inventors of Patent Medicines will thus be brought in the *direct contact* with the public be it through *selling* or *giving* samples thereof. When one considers the exorbitant expenses incurred by general advertising—which is actually the only way by which Patent Medicines can attract the attention of the public—*a more efficacious, and cheaper advertisement* which can be aided by the distribution of descriptive pamphlets can hardly be found.

The scheme does not commend itself to us. The Grand Central Palace is worthy of better things.

SOCIETY NEWS.

American Institute of Electrical Engineers.

The 93d meeting of the Institute will be held at 12 West 31st street, New York City, on Wednesday, January 16, at 8 P. M.

A paper will be presented by Prof. Alexander MacFarlane, of Ithaca, N. Y., "On the Units of Light and Radiation." The author expects to be present. A paper will also be presented by Mr. Alton D. Adams, of Boston, entitled "The Best Metal for Field Magnet Frames."

A meeting of Western members will be held the same evening, Wednesday, January 16, 8 P. M., at Armour Institute, 33d street and Armour avenue, Chicago, where, in addition to the above papers, Prof. Stine will present an illustrated historical sketch of the first three-wire Edison plant at Sunbury, Pa. If time permits, this matter will also be taken up at the New York meeting.

Applications have been received from the following candidates for associate membership, and will be acted upon by Council at its meeting, February 20, 1895: Robert C. MacCulloch, New York; B. C. Paddock, Jr., Boston, Mass.; Bernard Victor Swenson, Champaign, Ill.; Franklin Robert Anson, Salem, Oregon; Maxwell M. Mayer, New York; Joseph Nisbet LeConte, Berkeley, Cal.; Herman Loewenherz, Hoboken, N. J.; George A. Redman, Rochester, N. Y.; Arthur B. Cumner, Boston, Mass.; J. Lloyd Prince, Flatbush, L. I.; J. T. Nyhan, Macon, Ga.

LEGAL NOTES.

Mr. Muir's Railroad.

The Schenectady Street Railroad property has been sold at receiver's sale. The sale was made by P. C. J. De Angeles as special master appointed in the action of the Central Trust Company of New York. Under the judgment of the court the property could not be sold for less than $100,000, and it was required that a deposit of $10,000 be made by the bidder. The property was bid in by William H. White, Charles Batcheller and another. The price is said to have been $100,000.

The Western Electric Company; which represents the American Bell Company in the West, has begun an injunction suit in Chicago against the Harrison International Telephone Company for infringement of patents covering the telephone call box. There are three important suits covering the call boxes owned and controlled by the American Bell Company and its agencies and correlated companies. The first is the Thomas A. Watson patent of the switch in the call box; the second, the Elisha Gray patent telephone call box with magneto bell, and third, the Charles E. Scribner patent of the automatic crank switch for the call box. In the bill for injunction filed by the Western Electric Company the patents named are reviewed and their ownership by the plaintiff averred and the charge made that the Harrison Telephone Company "since April 1, 1893, have made, used and sold telephone call boxes which contained the devices named, and are causing to be made, sold and used such boxes."

The Seattle Consolidated Street Railway Company, the successor of the Seattle Electric Railway and Power Company, operating the Second street line and its branches in Seattle, Wash., has been sued in the United States Circuit Court under foreclosure proceedings brought by the Illinois Trust and Savings Bank of Chicago, trustee, on a mortgage for $400,000, covering an issue of bonds, March 15, 1890. Default in the payment of coupons under the trust deed was made April 1, 1894, and the bank now asks that the mortgaged property, covering all the holdings of the company, be sold as an entirety and without the right of redemption, to satisfy the sum due upon the bonds.

On the 8th inst., the Electric Railway Company of Savannah went into the hands of John R. Young as receiver under appointment by the United States Court on the petition of H. A. Pevear, of Lynn, Mass. The petition charges that over $1,000,000 worth of stock has been issued by those controlling the company, and parcelled out without any fair valuation being received in return. It is charged that certain parties interested in the company have run it to build up the value of lands, regardless as to whether it was solvent or not. Coupon bonds to a large amount are said to have been issued to stockholders without proper compensation. The value of property in the receiver's hands is placed at a half million of dollars.

THE LA ROCHE ELECTRICAL WORKS ASSIGN.

News is received as we go to press that the La Roche Electrical Works of Philadelphia have made an assignment. Details are not yet obtainable.

General News.

What is Going on in the Electrical World.

Norwalk, O.—An electric road between here and Bucyrus will be built as soon as the franchises can be secured.

Fergus Falls, Minn.—Clint J. Nichols, of Wahpeton, has been granted an electric light franchise and will put in a plant.

East Orange, N. J.—The township committee will petition the Legislature for permission to establish an electric light plant for the town's use.

Hull, Mass.—The Nantasket Electric Street Railway Company has been granted a franchise to construct and operate an electric railway in this town.

Bryan, Tex.—A receiver has been appointed for the Bryan Water, Ice and Electric Light Company, which was started in 1889 with a capital of $50,000.

Chicago.—Since the application of electricity to intramural transit nearly $1,000,000 have been expended in this city in the construction of power houses alone.

Charlottesville, Va.—A telephone exchange is to be established here. The 'phone made by the Fitzsimmons Telephone Company of Cincinnati, has been adopted.

Kokomo, Ind.—The Mowery Electric Light Company has made an assignment of its property. The assets of the company are estimated at $20,000; liabilities, $10,000.

Palestine, Tex.—The Palestine Electric Light Company's plant has been sold by the receiver to John R. Hearne. This was the first incandescent electric light plant put up in Texas.

Dickinson, N. D.—E. Hughes, of Bismarck, and Senator McGillivray, of this place, have nearly completed a deal for putting in an electric plant here to be run with lignite coal.

Schenectady, N. Y.—A test was made here a few days ago of the pulling power of an electric locomotive and a six wheel steam locomotive, with the result in favor of the electric machine.

Cleveland, O.—Arrangements have been made by the postal authorities with the Cleveland Electric Railway Company by which mail matter is to be carried to and from sub-stations along its various lines.

Gloversville, N. Y.—Subscriptions are being solicited for an electric railway proposed to be built between Gloversville and Broadalbin. Dr. M. F. Drury, of Broadalbin, heads the subscriptions committee.

Bismarck, N. D.—An ordinance has been passed by the council, and awaits the approval of the mayor, granting a twenty years' franchise to operate an electric lighting plant in this city to E. A. Hughes.

Decatur, Ill.—Representatives of a syndicate of Chicago capitalists have been here looking over the books and plant of the Decatur Electric Street Railway Company as a preliminary move toward purchasing the property.

Greensburg, Pa.—Judge Sadler, of Carlisle, who has been here in the interest of the Greensburg, Turtle Creek and Pittsburg electric railway, says that if the right of way is secured through Jeannette the road will be commenced at once.

New Haven, Conn.—The receiver of the Ansonia Electric Company has been granted legal permission to sell the company's works at Ansonia. Sealed bids for the plant will be received by Charles S. Mersick, the receiver, until the first Monday of February.

Logansport, Ind.—This city has its own electric light plant, consisting of 152 arc lamps. The new system was built by the Standard Company of Chicago at a cost of $50,000. The old Jenney plant will continue to furnish incandescent light and heat to private consumers.

Lima, O.—A company of Lima and Ft. Wayne capitalists has been organized in this city to construct an electric railroad which will connect five of the surrounding towns with Lima. The right of way has already been secured from Lima to St. Mary's and to Wapakoneta, a distance of 44 miles.

Seneca Falls, N. Y.—The highway commissioners have granted a franchise to the Waterloo, Seneca Falls and Cayuga Lake Railroad Company for the use of the new boulevard from the Easton farm to Cayuga Lake Park and the lake road north to Orchard Beach for the construction of a surface railway.

Media, Pa.—The Philadelphia and Rosemont Passenger Railway Company propose at an early day to build an electric road of the trolley system from Philadelphia to Rosemont on the Haverford road, and along the county line road between Delaware and Montgomery counties, and afterward extend the line from Rosemont to Bridgeport.

New York.—The New York and New Haven Railroad Company, it is said, is seriously considering the question of using electricity as a motive-power on its "short lines"—the lines which branch off from the main route and extend short distances to the minor summer resorts on the waters of the Sound and in the New England States.

Monticello, N. Y.—An electric railway connecting Monticello, Fallsburg, Woodbourne and Neversink will, it is thought, be built and in operation before the end of next summer. Mr. Van Cleft, of Newburg, is the promoter of the enterprise. Over $65,000 of the capital stock has, it is said, been subscribed.

Chatham, N. Y.—The Spengler Electric Light Company is using the water power of Chatham Centre in operating an electric light plant which is intended to furnish Chatham, Vatalie and Kinderhook with electric light. All the apparatus of the plant has been supplied and set up by the Standard Electric Company of Chicago.

Lancaster, Pa.—Edwin L. Reinhold and H. Burd Cassel, manager and treasurer of the Marietta Manufacturing Company, have purchased the plant of D. H. Kulp, who for some years has been an extensive manufacturer of electrical fans, and will carry on the business in the future. The plant will be operated here until preparations can be made for removal to Marietta.

Utica, N. Y.—At a meeting of the stockholders of the Utica Electric Light Company, held last week, these directors were elected: H. D. Pixley, M. Jesse Brayton, W. E. Lewis, R. T. McDonald (Fort Wayne, Ind.); T. Solomon Griffiths, Jos. Fox (New York); H. M. Scheuch. The directors elected the following officers: President, H. D. Pixley; first vice-president, R. T. McDonald; second vice-president, W. E. Lewis; secretary and treasurer, M. Jesse Brayton.

Boston.—The Lighthouse Board are making arrangements for the erection of range lights at South Boston, and are considering the use of electricity as an illuminating agent for these lights. Electricity has not been used hitherto for beacon purposes in Boston harbor.—The Boston Electric Light Company has sold $210,000 bonds to a New Haven party. This is a part of the issue recently authorized by the gas and electric light commissioners.

Concord, N. H.—The Railroad Commission reports to the Legislature that New Hampshire has now five street railways, of which three—the Manchester, Nashua and Laconia—are operated by horse power, and the other two—the Concord and Dover—by electricity. Arrangements are being made to convert the Manchester and Nashua roads into electrics. These roads, the report states, have passed from the ownership of the many people who furnished their original capital into the control of financiers.

Stockton, Cal.—The directors of the Electric Street Railroad Company are considering the advisability of establishing an electric plant of their own to furnish power for propelling the street cars, instead of renting the power from the Gas, Light and Heat Company.—A. J. Larson, of Lodi, who is working up the project for running an electric railroad from this city to Lodi, reports that the right of way and ten acres for each quarter section have been obtained for seven miles, or about half the distance between the two towns.

Denver, Col.—The claim is made in this city that it uses twice as much electric light as any other city of its size in the United States. The capacity of the two stations owned by the Denver Consolidated Electric Light Company is: Boiler capacity, 5,080 H. P.; engine capacity, 6,910 H. P.; illuminating capacity, 80,000 16-C. P. incandescent lights; 18,000 25-C. P. municipal incandescent lights; 2,240 2,000 C. P. arc lights, and motor services to the amount of 400 H. P. The officers of the company, recently elected, are E. W. Rollins, president; W. G. Fisher, vice-president; John H. Poole, general manager; W. W. Borst, superintendent, and A. E. Grier, secretary and treasurer.

Keokuk, Iowa.—J. C. Hubinger has made a proposition to the city council to the effect that if the city will grant him a contract to light Keokuk with electricity for twenty years he will agree to build a high bridge to extend from Fourth street in that city to the Illinois bluff at Hamilton, over a mile distant, the bridge to cost $400,000. He will, if properly encouraged, put a railroad track under the wagon track on this bridge, and also run an electric line across it, extending the lines to Carthage, Warsaw, Elvaston and Nauvoo, thus giving those towns freight, mail and passenger service, and supplying them with heat and light.

Niagara Falls.—A movement is on foot among several business men, providing there is another cold snap, to get up an electric ice carnival here. Some merchants have already promised to subscribe toward such a project, and say that while the short winter season here would not admit the building of an ice palace, the beautiful natural scenery about the Falls and parks could be gloriously illuminated with electric lights and present a picture that would never be equaled elsewhere. Some of the enthusiastic ones say electric cables of lights of various colors could be strung in front of the great Falls, also across the gorge and through the parks. The scenery, so beautiful in the day, would be intensified at night and thousands would be attracted here to see it.

Los Angeles, Cal.—There is in Los Angeles something over 100 miles of street railroad tracks, comprising electric, cable and horse car routes. These roads have carried about 9,000,000 people during the year that has just closed. The cable system has about twenty miles of tracks and originally cost $2,000,000. Its whole system is double tracked. The electric system has about fifty-five miles of track, the greater portion of which has been double-tracked. During the present year it is the intention to change nearly all of the cable lines into electric systems, which will necessitate great improvements in the power houses and also the purchasing of a large amount of electrical material. The Westinghouse works in Pittsburg, Pa., have already contracted to supply the latter.

Tacoma, Wash.—The Pierce County Power and Telegraph Company have applied for permission to build and operate an electric power plant in Tacoma for manufacturing, railway and other purposes. They propose to put a dam across the Nisqually in order to get a fall of water to run the dynamos, and will put in a large amount of expensive machinery.—A new company has been formed here growing out of the purchase and combination of the Tacoma Light and Water Company with the Commercial Electric Light and Power Company. The reputed purchasers are Seymour, Barto & Co., C. B. Hurley, and some Eastern men who make a specialty of the gas business. Mr. Hurley has become manager of the consolidated plants.

Trade Note.

The Metropolitan Electric Company, 186-188 Fifth avenue, Chicago, have recently been making some changes in their store and have put in some new counters and shelving, thus adding to its attractiveness and furnishing better facilities for the display of their increased line of goods.

The Partridge Carbon Company.

The prospects of the Partridge Carbon Company of Sandusky, O., for the coming year are very bright. Railroad companies have not been slow to recognize that quality counts more than original cost as a factor of economy in carbon brushes. The factory is running overtime, working chiefly on the "Partridge S. L. Brush."

INCORPORATIONS.

The Foreign Electric Traction Company, Alexandria, Va.—to manufacture electric apparatus. Capital stock, $1,000,000. Promoters: W. M. Stewart, P. B. Thompson, G. Y. Atlee, W. M. Wheelis, Washington, D. C.

The Kings County Electric Light and Power Company, Jersey City, N. J.—to manufacture and use electricity for producing light, heat and power. Capital stock, $1,000,000. Promoters: Edwin C. Low, Brooklyn, N. Y.; Henry R. Burr, Amityville, N. Y.; Hugo G. Adam, Montclair Heights, N. J.

The Farquhar Electric Company (incorporated in West Va.), Suffolk, Mass.—to manufacture and lease electrical machinery and appliances, etc. Capital stock, $1,000,000. Promoters: Donald H. Farquhar, Chas. H. Whitcomb, Frank L. Whitcomb, Boston, Mass.

The Southern Ohio Telephone and Telegraph Company, Hamilton, Ohio—to erect and operate a system of communication by electricity, telephone or telegraph instruments. Capital stock, $35,000. Promoters: Wm H. Pfau, Frank P. Richter, F. W. Clements, C. C. Morey, H. H. Haines.

The Mt. Clemens and Lakeside Electric Street Railway and Dock Company, Lakeside, Mich.—to build and run a general electric railway. Capital stock, $25,000. Promoters: B. B. Conisin, Mt. Clemens, Mich.; Evan Jones, Geo. L. Fl[illegible]cher, W. C. Cunderfinger, Pittsburg, Pa.

Colorado Electric Placer Mining Company. Capital stock, $[illegible]00,000. Incorporators: Erastus S. Bennett, Geo. W. Van Norwick and Frank E. Badger.

The Farnsworth Propeller Company, Chicago, Ill.—to manufacture or sell steam or electric propellers for water navigation, under patents issued by the U. S. Patent Department; own real estate and buildings necessary for the shipbuilding business. Capital stock, $2,000,000. Promoters: Addison Bybee, P. Malden, Frederick J. Patterson.

The Trenton Traction Company, Trenton, N. J.—to buy, acquire, lease and operate street or surface railways. Capital stock, $500,000. Promoters: E. J. Moore, Philadelphia, Pa.; Thos. C. Barr, East Orange, N. J.; Francis M. Eppley, West Orange, N. J.; Geo. B. Jenkinson, Newark, N. J.

The Cartersville Light and Power Company (incorporated in W. Va.), Cartersville, Ga.—to manufacture, distribute and sell illuminating or fuel gas or electric light and power, etc. Capital stock, $100,000. Promoters: Peter W. French, Weymouth, Mass.; T. Putnam Symonds, Salem, Mass.; Wm. E. Merill, Haverhill, Mass.

The Loop Construction Company, Chicago, Ill.—to build and construct elevated and electric railroads; furnish materials and appliances for same. Capital stock, $1,000,000. Promoters: Douglas Hotchkiss, Geo. E. Newlin, Wm. M. Johnson.

The Rushville Electric Light Company, Rushville, Ill. Capital stock, $12,500. Incorporators: C. W. Weinman, John Foote, H. Wells and John S. Little.

The Elyria, Oberlin and Wellington Electric Railroad Company, at Toledo, Ohio—to construct and operate an electric railway eighteen miles long. Capital stock, $100,000. Incorporators: A. R. Webber, W. A. Braman, R. J. Reefy, W. B. Bedortha, Charles A. Metcalf, J. W. Steele, A. H. Johnson and Parks Foster.

The Tri-Village Telephone Company—to connect Fort Edward, Sandy Hill, Glens Falls and South Glens Falls, N. Y. Capital stock, $2,500. Directors: Marcus C. Allen, J. E. Howland, of Sandy Hill; Joseph E. King, F. B. Davis and G. C. Beverly, of Fort Edward, J. W. Hunting and J. I. Dunn, of Glens Falls.

The Cushman Electric Company, Saco, Me.—to manufacture electrical apparatus. Capital stock, $300,000. President, B. A. Kimball, of Concord; treasurer, Ambrose Eastman, of Boston.

The Maine Electric Company, Portland, Me.—to manufacture and deal in all kinds of machinery and electrical supplies. Capital stock, $10,000. President, Wm. M. Lamb, Cumberland Mills; treasurer, O. Warren Neal, Westbrook.

$1,000,000. Promoters: T. J. Ryan, Geo. W. Walts, F. Milton Johnson, G. W. Fleming, Harvey W. Snow, San Francisco.

The Knoeller Car Improvement Company, Jersey City, N. J.—to acquire by purchase patent and patent rights for improvements for use in electric, cable and street cars, etc. Capital stock, $5,000. Promoters: Jas. Ridley, Patrick A. Kilroy, Daniel Y. Lewis, Geo. B Fielder, Jersey City.

The World's Flash Company, Chicago, Ill.—to manufacture, buy and sell electrical appliances of all kinds and electrical machinery. Capital stock, $90,000. Promoters: Leroy D. Thoman, Fred. W. Harnwell, Walter S. Holden.

The Gerson Electrical Manufacturing Company, Philadelphia, Pa.—to manufacture iron and steel, etc. Capital stock, $50,000. Promoters: Chas. Hermitage, Louis J. Gerson, Philadelphia; F. C. Rice, Brooklyn, N. Y.

The Pacific Mineral Reduction Company, San Francisco, Cal.—to prosecute mining and milling; deal in water rights and construct ditches, electric light plants, and supply power for manufacturing purposes. Capital stock,

Watseka Automatic Telephone Company, Chicago Capital stock, $10,000. Incorporators: W. H. Harry, H. Darlington and E. E. Wood.

The Tillamook Electric Railway, Power and Light Company, Tillamook, Oregon—to build, own and operate an electric railway. Capital stock, $500,000. Promoters: W. H. H. Cary, Davis Hess, Wm. Squires, Tillamook.

The Electric Bell and Resistance Company, Newark, N J.—to manufacture and deal in electrical devices and electrical supplies. Capital stock, $10,000. Promoters: Geo. F. Atwood, Isaac M. Williams, Orange, N. J.; Jas. P. McKenna, Newark.

The Ceramic City Light Company, Chicago, Ill.—to generate electricity for use in furnishing light, heat and power, and distribute and sell the same. Capital stock, $50,000. Promoters; Philip M. Smith, Chas. M. McKeehan, Wm. E. Smith, Alex. R. Wells A. Curtis Vandyke.

Woven Wire Brushes.

The Belknap Motor Company of Portland, Me., are the patentees and manufacturers of the best Woven Wire Brush on the market.—[*Adv.*

ELECTRICAL PATENT RECORD.

LETTERS PATENT ISSUED JANUARY 1-8, 1895.

ELECTRIC RAILROADS AND APPLIANCES.

531,664. Closed Conduit for Electric Railways. Robert J. Turnbull, St. Paul, Minn., assignor of one-half to Augustus F. Priest, same place. Filed Jan. 19, 1894.

531,837. Trolley. Theodore Cooper, Providence, R. I. Filed Sept. 17, 1894.

531,873. Electric Railway. Abraham A. Shobe and William Embley, Jerseyville, Ill. Filed July 24, 1894.

531,980. Electric Rail-Bond. George E. Somers, Bridgeport, Conn. Filed May 7, 1894.

532,031. Self-Adjusting Trolley. John Corcoran, Harrisburg, Pa., assignor of one-half to Alfred T. Black, same place. Filed Aug. 29, 1894.

532,057. Motor Suspension for Electric Street Cars. Samuel Harris, Cleveland, O. Filed May 19, 1894.

532,113. Converter System for Electric Railways. George W. Swartz, Florence, Ala. Filed Oct. 12, 1893.

532,126. Supply System for Electric Railways. Albert G. Wheeler, Chicago, Ill., assignor to the Love Electric Traction Company, same place. Filed Jan. 21, 1893.

532,133. Trolley-Wire Clip. Johan M. Andersen, Boston, Mass., assignor of one-half to Albert Anderson, same place. Filed July 9, 1894.

532,157. Underground-Trolley Arm. Paul C. Just, Chicago, Ill., assignor to Albert G. Wheeler, same place. Filed Jan. 4, 1894.

532,163. Conduit Tramway. John C. Love, Philadelphia, Pa., assignor to the Love Traction Company, Chicago, Ill. Filed Sept. 5, 1893.

532,165. Conduit for Electric Railways. John C. Love, Chicago, Ill., assignor, by direct and mesne assignments, to the Love Electric Traction Company, same place. Filed May 9, 1894.

532,167. Electric-Railway Trolley. John C. Love, Chicago, Ill., assignor, by direct and mesne assignments, to the Love Traction Company, same place. Filed May 9, 1894.

532,168. Trolley-Wire Clamp. John C. Love, Philadelphia, Pa., assignor to the Love Electric Traction Company, Chicago, Ill. Filed July 11, 1892. Renewed Oct. 13, 1894.

532,185. Conductor-Bond for Meeting Ends of Rails of Electric Railways. Peter Rieth, Chicago, Ill., assignor of two-thirds to John McGeean and James McGeean. Filed June 14, 1894.

532,195. Trolley-Support. Lucius T. Gibbs, Milwaukee, Wis. Filed July 28, 1893.

532,200. Trolley for Electric Railways. John C. Henry, Westfield, N. J. Original application filed Sept. 27, 1889. Divided and this application filed March 8, 1893.

532,261. Conduit Electric Railway. Albert M. Burgher, Clay City, Ky. Filed April 17, 1894.

532,302. Closed Conduit for Electric Railways. Frank Windle, Philadelphia, Pa. Filed March 8, 1894.

ELECTRIC LIGHTS AND APPLIANCES.

531,663. Base for Incandescent Electric Lamps. George C. Thomas, South Framingham, Mass. Filed Nov. 28, 1893.

531,698. Electric-Arc Lamp. Charles A. Pfluger, Chicago, Ill., assignor to the Standard Electric Company, same place. Filed April 5, 1894.

531,729. Adjustable Hanger for Incandescent Lamps, Gas Fixtures, etc. Harry W. Lawrence, Denver, Colo., assignor to the Electrical Specialty Company, same place. Filed Dec. 1, 1893.

531,751. Electric-Arc Lamp. Albert Schweitzer, Allegheny, Pa., assignor of two-thirds to Frederick Goellner, same place, and Conrad Weber, Shaler, Pa. Filed June 22, 1894.

531,840. Adjusting Mechanism for Arc-Light Carbons. Elie F. G. H. Faure, Schenectady, N. Y., assignor to the Thomson-Houston Electric Company, same place. Filed Aug. 22, 1894.

531,978. Electric Arc Lamp. Chas. E. Scribner, Chicago, Ill., assignor to the Western Electric Company, same place. Filed March 7, 1891. Renewed May 9, 1893.

532,095. Electric Arc Lamp. Amos W. Richardson, Patricroft, England. Filed March 2, 1894.

532,103. Electric Lamp Support. Frank Schefold and James Nortney, New Albany, Ind. Filed March 1, 1894.

DYNAMOS, MOTORS, ETC.

531,623. Armature for Dynamo-Electric Machines or Motors. Ward Decker, Owego, N. Y. Filed Nov. 17, 1892.

531,657. Transmuter for Electrical Currents. William J. Still, Toronto, Canada assignor of one-half to Randolph MacDonald, trustee, same place. Filed April 5, 1893.

531,707. Brush for Dynamo-Electric Machines. John B. Wallace, Ansonia, Conn., assignor to the Wallace Electric Company, of Illinois. Filed April 30, 1894.

531,790. Method of Operating or Controlling Electric Motors or Dynamos. Rudolf Eickemeyer, Yonkers, N. Y. Filed Nov. 2, 1891.

531,821. Constant-Current Dynamo. James J. Wood, Fort Wayne, Ind. Filed July 3, 1894.

531,996. Electric Converter. Robert H. Hassler, Pittsburg, Pa., assignor to the Westinghouse Electric and Manufacturing Company, same place. Filed April 30, 1894.

BATTERIES.

532,128. Storage Battery. Theodore A. Willard, Norwalk, Ohio. Filed Jan. 5, 1894.

TELEPHONE AND TELEGRAPH APPARATUS.

531,650. Telephone Indicating Apparatus. John I. Sabin and William Hampton, San Francisco, Cal. Filed July 25, 1894.

531,677. Printing-Telegraph. Samuel V. Essick, Yonkers, N. Y. Filed April 20, 1893.

531,854. Telegraphic Transmitter. John J. O'Neill, New York, N. Y. Filed Feb. 23, 1894.

531,913. Telephone-Switch. Augustus G. Davis, Baltimore, Md. Filed Nov. 23, 1893.

MEASURING INSTRUMENTS.

531,866. Method of and Means for Measuring Energy of Alternating Electric Currents. Oliver B. Shallenberger, Rochester, Pa. Filed Sept. 19, 1894.

531,867. Method of and Means for Measuring Alternating Electric Currents. Oliver B. Shallenberger, Rochester, Pa. Filed Sept. 19, 1894.

531,868. Indicating Watt Meter for Alternating Electric Currents. Oliver B. Shallenberger, Rochester, Pa. Filed Sept. 19, 1894.

531,869. Watt Meter for Multiphase Alternating Electric Currents. Oliver B. Shallenberger, Rochester, Pa. Original application filed Sept. 19, 1894. Divided and this application filed Nov. 24, 1894.

531,870. Alternating-Current Measuring Instrument. Oliver B. Shallenberger, Rochester, Pa. Filed Nov. 24, 1894.

531,970. Electrostatic Voltmeter. Henry A. Rowland, Baltimore, Md. Filed Feb. 24, 1894.

SIGNALS AND SIGNALING APPARATUS.

531,651. Electric Block-Signal. Charles H. Sallada, Pittsburg, Pa. Filed April 9, 1894.

531,669. Indicator for Electric Currents. Edward Weston Newark, N. J. Filed Feb. 21, 1894.

531,708. Electric Signal. William J. Wessenberg and Horatio F. Wilbur, Meriden, Conn. Filed Aug. 12, 1893.

531,919. Electric Railway-Signal. Jake Frank, New York, N. Y. Filed Nov. 27, 1893.

532,008. Electric Signaling Apparatus. George E. Miller, Saugus, Mass., assignor to the American Electric Train and Switch Signal Company, Portland, Me. Filed Jan. 24, 1894.

532,009. Electric Semaphore-Setting Device. Homer A. Parrish, Jackson, Mich. Filed Feb. 10, 1894.

532,122. Railway Signal. James Wayland, Newark, N. J. Filed Jan. 24, 1894.

532,291. Electric Burglar Alarm. Horace M. Scholes and George M. Meyers, Kansas City, Mo. Filed April 17, 1894.

MISCELLANEOUS.

531,635. Electric Wire Holder or Insulator. Albert Iske, Lancaster, Pa. Filed May 29, 1894.

531,690. Phonograph. Stewart D. McKelvey, Canton, Ohio, assignor of one-third to Joseph A. Linville, same place. Filed March 31, 1892.

531,702. Cleat for Electric Wiring. Joseph H. Swift and William F. Maintien, Plainville, Mass. Filed March 17, 1894.

531,709. Electro-Magnet. William J. Wessenberg and Horatio F. Wilbur, Meriden, Conn. Filed Sept. 27, 1894.

531,764. Electric Car-Lighting Apparatus. William Biddle, Brooklyn, N. Y. Filed May 8, 1894.

531,765. Circuit-Regulating Device in Electric Car-Lighting Apparatus. William Biddle, Brooklyn, N. Y. Filed May 28, 1894.

531,849. Electric Steam-Engine Governor. Chester B. Melott, Rondout, N. Y. Filed July 21, 1894.

531,890. Coin-Controlled Electrical Musical Instrument. Philip Wuest, Jr., Philadelphia, Pa. Filed Sept. 12, 1893.

531,929. Safety Device for Electric Circuits. Thomas Harden, London, England. Filed April 27, 1894.

531,961. Circuit-Controller. Thomas Parker, John H. Woodward, and Edmund S. G. Rees, Wolverhampton, England. Filed Feb. 24, 1892.

531,962. Distribution of Electricity. Thomas Parker, John H. Woodward and Edmund S. G. Rees, Wolverhampton, England. Filed Feb. 24, 1892.

532,016. Electrically-propelled Vehicle. Henry C. Baker and John R. Elberg, Kansas City, Mo. Filed April 6. 1894.

532,101. Insulator for Electric Wires. Daniel M. Rothenberger, Lancaster, Pa., assignor of one-half to Chas. A. Inglis, same place. Filed April 4. 1894.

532,160. Insulator. Myron D. Law, Washington, D. C., assignor to Albert G. Wheeler, Chicago, Ill. Filed Aug. 29, 1893.

532,161. Conductor. Myron D. Law, Washington, D. C., assignor to Albert G. Wheeler, Chicago, Ill. Filed Sept. 28, 1894.

532,164. Conductor Support. John C. Love, Chicago, Ill., assignor, by direct and mesne assignments, to the Love Electric Traction Company, same place. Filed May 9, 1894.

532,166. Tension Device for Electric Conductors. John C. Love, Chicago, Ill., assignor, by direct and mesne assignments, to the Love Electric Traction Company, same place. Filed May 9, 1894.

532,188. Electric Hair Clipping Machine. Peter Shannon, Chicago, Ill. Filed April 27, 1894.

532,260. Cross-Arm for Support of Electric Wires. Edward J. Bullock, Wallingford, Conn. Filed Nov. 19, 1894.

532,353. Lightning Arrester. Alexander Wurts, Pittsburg, Pa., assignor to the Westinghouse Electric and Manufacturing Company, same place. Filed Feb. 28, 1894.

532,354. Lightning Arrester. Alexander J. Wurts, Pittsburg, Pa., assignor to the Westinghouse Electric and Manufacturing Company, same place. Filed Aug. 3, 1894.

ELECTRICITY.

VOL. VIII. NEW YORK, JANUARY 23, 1895. No. 2

ELECTRICITY.

Published every Wednesday by the

ELECTRICITY NEWSPAPER CO.

B. E. GREENE, PRES'T. L. J. MONTGOMERY, SEC'Y.

PUBLICATION OFFICE:

6 Park Place - New York

EDITORS: NELSON W. PERRY.
BURTON E. GREENE.
R. H. WILLOUGHBY.

SUBSCRIPTION RATES:

United States, - - - - $2.50
In Clubs of Five or More, - - - - - $2.00
Foreign Countries, - - - - - - $4.50
Single Copies. - - - - - - 10 Cents

ADVERTISING RATES:

As ELECTRICITY reaches all classes interested in electrical work, its value as an advertising medium can be readily appreciated. Rates will be sent on application.

Changes for advertisements should reach the office not later than the Saturday preceding the date of publication.

ENTERED AT THE N. Y. POST OFFICE AS MAIL MATTER OF THE SECOND-CLASS.

TRADE SUPPLIED BY
THE AMERICAN NEWS COMPANY,
THE WESTERN NEWS COMPANY,
And their Agencies in all Principal Cities.

N. E. L. A.—The next annual meeting of the National Electric Light Association will be held at Cleveland, O., February 19-21, 1895. Every concern interested in either lighting or railway work should be represented in the membership of this body, and should have at least one representative at the Cleveland meeting. The Secretary is Mr. Geo. F. Porter, 136 Liberty street, New York.

EDITORIAL NOTES.

The Brooklyn Trolley Strike.

At last we are confronted with a strike of large proportions on the trolley roads, and as we go to press it is announced that the situation has become so serious in Brooklyn as to necessitate, in the opinion of the authorities, the calling out of the New-York troops. Under such circumstances it is customary for the editor to moralize and indulge in platitudes, but these resorts avail nothing. We are sorry that recourse to the usual strike methods has found its place among electrical workers. Granted that both parties to the controversy are partly right and partly wrong, the striker starts out with the sympathy of the public. So far he has an immense advantage over the corporation for which he works, but he loses that advantage so soon as he resorts to strike methods. He nullifies the effect of his own arguments by resorting to the very methods with which he is finding fault. The company, he says, is overbearing, autocratic,—and then in trying to fight this company the striker becomes ten times more overbearing and autocratic. He says he will not work for such wages or for such hours as are required, and he has a perfect right to say this, but then he goes further and says no one else shall work under these conditions, and the company shall not conduct its business unless it conducts it according to his ideas.

The laboring man or mechanic must understand that the company for which he works is as much a creature of circumstances as he himself is. It must cater to the public—to its customers—if it would live. There is no corporation so strong that it may say with impunity, "The public be damned." Only in so far as it successfully caters to its patrons' wants can it succeed. Only in so far as it conducts its business successfully can it pay wages. The poorer we are the more necessity do we find for curtailing expenses. This applies less to the wealthy than to the poor, but the law is inflexible. If a corporation is wealthy it can afford to pay better wages—whether it does so or not is a different matter—but in so far as its capacity for earning money is crippled just so far will its *ability* to pay good wages be lessened—and that is the method into which all strikes sooner or later degenerate, viz., in trying to force higher compensation by crippling the capacity of capital to pay anything. The whole thing is illogical and a repetition of the mistaken policy of killing the goose that lays the golden eggs. Resort to legislation has been proposed and tried, both to regulate the price of labor and to regulate the price of other commodities, but it has in all cases failed, and must in all cases fail. It is no more possible to regulate the price of a commodity by law—and labor, whether it be skilled or menial, is a commodity—than it is to regulate in the same way the ebb and flow of the tides. The price of any commodity is regulated by the law of supply and demand, which is quite as inflexible as the other natural laws which control the movements of the heavenly bodies and of the tides.

Each individual, however, can do something to increase the wages he will get, and that something is to increase the actual value of his services by becoming more expert in that which he undertakes to do. A skilled mechanic need fear no competition from workmen of an inferior grade. The more selfish the corporation that comes into the labor market the stronger will be the position of the skilled artisan, for the simple reason that he can make more money for his employer with less expenditure of labor. No legislation, however severe, can place upon a par two things which are not intrinsically equal. The law cannot make two dollars equal to three dollars of the same money, nor can it make inferior services equal to those that are superior. The unions, too, can do much. They can elevate the character and quality of the material of which they are composed. It should be their province to have laws passed making membership in their organizations contingent upon real merit. Then to wear the badge of the union would be to wear the badge of merit, and capital would come to the union for its labor, not because of threatened disaster if it went elsewhere, but because of its very cupidity, that it could thereby make more money. They should agitate the passage of State laws requiring that electrical workers, say, should be up in their business before they are qualified to enter the trade. They should be required to pass an examination before some competent tribunal and receive a certificate of proficiency before they are permitted to enter the ranks. Just how high this standard of proficiency should be is a matter that should probably be left to the unions to decide. Probably it would be best to have several standards from which the novice might pass by successive stages as his proficiency entitled him to advance. There would be no competition between these different grades, because there can be none between merit and demerit, but there would be a competition in skill between the members of the same grade with the laudable incentive to step higher up to a position where their services would command more consideration by reason of their greater intrinsic value. But this would be solely a competition of merit wherein the men themselves would be the sole judges.

The employer, too, has not less to learn than the employed. So long as he conducts himself so as to give ground to the suspicion that he will take unfair advantage of his employees—that he is seeking opportunities to grind them down—so long will the employee rebel, whether he be skilled or unskilled. His first duty is to dispel this idea of unfairness, and if it requires greater sacrifices on his part to accomplish this, still he must do it, or that potent influence called "public opinion" will be arrayed against him. Each side must be absolutely fair to the other, and above all let the employee be fair to himself. Let him not attempt to foist upon the employer as an equal one whom he knows is his inferior. It is unfair to himself, unfair to the union and unfair to the employer.

* * *

The Fixture Trust. Of all the attempts at forming Trusts none had fewer chances of success than the so called Fixture Trust, none flattened out so quickly and so completely, none was so ridiculously managed. One by one all Trusts are dissolving, and a few years more will see the last of these attempts, in this generation, to overturn the law of supply and demand, the law of competition, and all other sound business laws upon which the world's commerce has been built up.

Mr. Clement M. Biddle, the originator of the Fixture combination, had made money in one or two other similar trades and had grown too confident. In order to bring recalcitrant concerns into line he offered to buy them outright, offering any price, even twice their value, but always in-notes with little cash. All but one or two were gathered in, the firm of Horn, Brannen & Forsyth being the most conspicuous one to remain outside.

The Trust was scarcely completed when disaster began to pile up thick around its various branches and disintegration was forced.

The patents of Mr. Luther Steiring, owned by Mailland of Detroit, were relied on to bring in a large revenue, and they did so for a year or two until defeated in the courts by the Gibsons of Philadelphia. Nearly every house in the trade had agreed to pay a 3 per cent. royalty on their gross business; but this arrangement was short-lived and the field was open again.

Some of the pillars of the combination, Archer Pancoast, Oxley Giddings and others, were forced into bankruptcy and large losses sustained by both stockholders and creditors.

The General Fixture Company shared in the disaster, and it is now rumored that an appraisement is to be made and the property sold. The Northwestern Hardware Company (the name the Trust was to work under) had paid on account of the purchase of this company about $200,000 and given $400,000 in notes. They now claim the condition of the concern was misrepresented and are suing to recover the money paid and to cancel the remaining notes. Meantime the company has been a financial charge upon its parent, the General Electric Company.

The business of every concern which went into the combine was badly injured and some were ruined completely. The promoters themselves have lost large amounts of money, and there has been nothing but disaster from start to finish.

With the wrecks of 75 per cent. of all Trusts formed in the past ten years before us, is any further argument necessary to prove that the fundamental idea of Trusts was wrong, is wrong, and always will be wrong?

* * *

A Sound Idea. The Hartford (Conn.) Board of Fire Underwriters have taken steps to compel electric wiremen to pass an examination before being allowed to work at their trade in that city. Charles E. Chase, president of the board, has been instructed to appoint a committee to present the facts to the Court of Common Council and ask that no wiring of houses be permitted by any except licensed electricians. The passage of such an ordinance in any city would insure the work being done by competent men, and in a way to reduce the danger of fires, etc., to a minimum.

In many cities steam engineers are compelled to undergo examinations and to work under licenses. There are many reasons why those in control of electrical plants, and wiremen also, should be under similar official regulation.

True, the danger of explosions is not present in electrical apparatus, but there are other dangers equally serious. Such a plan would work to the advantage of competent men, and would at once produce a higher standard of service. In the wiring branch alone there is urgent necessity for its adoption, and if properly enforced its benefits to the public and to the better class of workmen would be manifest.

This is one of the few questions which are almost beyond argument. No sound objections could be offered by any one. Hartford is on the right track, and we hope other cities will take up the subject at once.

* * *

Falling into Line. For some time the New York, New Haven and Hartford Railway Company have suffered from the competition of the trolley systems which parallel and cross their lines at scores of points through New England. Their last two annual reports have commented on the bad effects of this competition on the system, and the railway company have made several attempts to hamper intended trolley competitors by bringing annoying suits to prevent the latter from crossing the tracks of the former.

Now it is announced that the New York, New Haven and Hartford Railway Company have decided to equip two of their branches with electrical motive power. One of these is the Nantasket Beach line, which conveys passengers to that resort chiefly in summer. The other is the line from Providence to Fall River, conducted in connection with the Sound steamers. The latter road is about forty miles long. One of the officers of the road has called attention to the fact that the four-track system between New York City and New Haven, about seventy miles long, is in such a condition and is so constructed as to permit the use of electricity as soon as it is made clear that a change of this magnitude is warranted.

Whether electricity as a motive power will ever displace steam on trunk lines is still an undecided question. But that it may be adopted on innumerable branches of steam roads with profit and satisfaction there is scarcely a doubt. We are glad that the leading railway system of New England, where the influence of the trolley cars has been most felt, have given up fighting the march of progress and decided to join in the procession.

It is also announced that the Brooklyn elevated railroads, alarmed at the inroads the trolley cars have made on their receipts, are about ready to adopt electricity and to add an elevator service to each of their stations.

Thus the public are placed under obligations to the promoters of the trolley system, who are forcing the adoption of better and more enjoyable rapid transit facilities than were dreamed of ten years ago. And whatever plans may be adopted by its competitors the trolley will maintain its position.

* * *

The Cleveland Convention. There is every indication that the Cleveland meeting of the National Electric Light Association will be a thorough success. The programme arranged so far is an excellent one, and gives promise of a series of vigorous discussions.

There is sure to be a large attendance. ELECTRICITY has in preparation a special issue for this meeting which will be fully worthy of the occasion. It is not our custom to get out a special issue every second week, and when we announce one we do so in the full assurance that we can offer advertisers a *special* opportunity of being represented in a paper which will be thoroughly read for its interesting matter and then preserved as a work of art. Orders should be placed at once.

Under the Searchlight.

Views and Opinions on Timely Topics.

In an early issue we will publish a complete list of the stocks and bonds carried on the G. E. books as assets, also those sold to the Securities Company, the Electric Corporation, and the Street Railway and Illuminating Properties, with the total capitalization of each of the local companies. It should be preserved for reference.

* * *

Last year the G. E Company had $8,000,000 of patent assets—so they said. The only patents of value have now either expired or been declared invalid, and the patent account, we fear, will soon be in debt to "shop cost" or to profit and loss account.

* * *

The Offer is Still Open.

Electricity offers to put up $200 with any party to be agreed on, the *Electrical World* to put up an equal amount, the sum to be divided between the A. I. E. E. and the N. E. L. A., to prove whether the *Electrical World* has or has not 4,000 paid subscribers. Decision to be rendered by a committee of three, each side to choose one, the two to choose the third.

Step up to the captain's desk, Mr. Johnston.

* * *

The Cause a Mystery.

(From the Elmira Gazette.)

Patrons of the Elmira and Horseheads Street Railroad must have noticed that at times recently the current would desert the trolley and the car would stop. Many of them will be surprised to learn that the cause of this is a mystery. Superintendent Cheney of the electric light station is a great electrician, but he has failed to discover the cause. Many others have looked for it, but they, too, have been unsuccessful.

A few years ago, before the service of the New York Steam Company had reached its present state of perfection, there were several leaks in Mail street from the company's pipes—veritable geysers rising high in air. They remained there for days, and when the reporters sought the manager, Mr. F. H. Prentiss, he told them he had been unable to find the cause. The New York *Times* suggested that Mr. Prentiss be compelled to sit on one of the geysers until he discovered the cause. Perhaps Superintendent Cheney better be compelled to ride the trolley until he finds out why the current persists in deserting.

* * *

Speaking of bribery, how would some of the expense sheets of the old "special agents" look in cold type?

* * *

Maps and Their Uses.

We have received several copies of a map of a great portion of the world, upon which have been engraved a large number of figures, purporting to show the circulation of the *Electrical World* in various States and countries, which leads us to consider the question of maps.

Not many years ago when Richard Croker, "Awful" Gardner, Owney Geoghegan, Judge Norton, Fatty Walsh and other prominent men were shining ornaments of the prize ring, when prize fighting was as common as meetings of good government clubs are nowadays, and when the reports of scrapping matches formed a leading feature of the regular news of the day, the New York *Herald* managed to beat its contemporaries regularly in obtaining reports of the fights. They had so many scoops that the city editors of many other papers were in danger of losing their jobs.

Finally a reporter on the Brooklyn *Eagle* conceived a brilliant idea. He bought a real estate map of the city of Brooklyn and started in on his own hook to report prize fights from his room in a boarding house. Night after night he located and described in detail bloody mills, first in one section of the city, then in another, on vacant lots. He beat the *Herald* so often that they sent an army of reporters to Brooklyn, until every second man on the street was a *Herald* reporter looking industriously for a prize fight. At last, by mistake, a fight was located on premises which were directly under the windows of a station-house. The police officers investigated the source of the *Eagle's* news, and the bright reporter was compelled to throw away his map and again devote himself to reporting events which had taken place.

The circulation story told by the map of the *Electrical World* is about as truthful as the stories of fights told by the *Eagle* reporter and his now famous map.

* * *

Street Railway and Illuminating Properties.

The trustees of Street Railway and Illuminating Properties have retired 939 additional shares of preferred stock, paying an average price of 110⅛ flat. This makes a total of 28,500 shares purchased to date and leaves outstanding 21,500 shares.

The profits of this syndicate will be more than enough to have paid a 5 per cent. dividend on the G. E. common stock for two years.

* * *

Buffalo and the Falls Power Scheme.

Buffalo has been in a turmoil for some weeks over the question of granting to the Niagara Falls Power Company a franchise enabling it to get the Niagara power into the city.

It is now made known that the Buffalo General Electric Company's franchise is sufficient for all the needs of the Power Company.

The deal between the General Electric Company and the Niagara Falls Power Company's interests, mentioned in Electricity some weeks ago, is in a fair way to be uncovered.

* * *

Boston men were blamed for the over-valuations in the first report of G. E. Who will be blamed for the over-valuations in No. 2? Let us wait and see.

* * *

They do strange things in Philadelphia. A recent illustration in the *Inquirer* of that city showed an attaché of the Electrical Bureau in the City Hall engaged in the diversion of killing rats by electricity. It was stated that the rats are first caught in ordinary traps.

* * *

Electricity confidently expects such a thorough reorganization of the G. E. Company this year as will allow us conscientiously to extend the right hand of fellowship and welcome it back to the ranks of honest companies minding their own business and not interfering with the rights of others.

* * *

The Electrical Trust was not a funny term in 1892, but in 1895 it sounds like a joke.

* * *

The *Wall Street News* states that the Thomson Regulator patent was carried on the G. E. books at $2,000,000.

The National Electric Light Convention.

The Trunk Line Association have granted a rate of a fare and a third for the round trip, on the certificate plan, for members and delegates attending the Eighteenth Convention, to be held at Cleveland, February 19, 20 and 21. Negotiations are now pending for a special train from New York to Cleveland, notice of which will be given as soon as route is selected and schedule arranged.

Truth is Stronger than Fiction.

"Electricity" Makes No Statements Which Are Not Easily Verified by Others.

(From Electricity, Jan. 2.)

But admitting that the debts are paid, that bonds have been retired, how has it been done? From profits in the business? Certainly not. They (the G. E. Co.) have sold during the year a large amount of local securities, have cleaned up a number of bad accounts, and with the proceeds from these two sources they have reduced their debts and retired some bonds.

(Inspired Financial Paragraph, Jan. 3.)

The allegation that the $1,000,000 bonds retired last year were not paid out of earnings is declared to be untrue, as the company now depends upon its earnings rather than new capital for all its expenditures. This has been true ever since the St. R. and Ill. Properties issue.

A TRUTHFUL DIRECTOR.

What Do Messrs. J. P. Morgan & Co. Say to This?

(From the Lynn (Mass.) Item, Jan. 12, 1895.)

A General Electric director says the only indorsement likely to be outstanding at the end of the fiscal year will be $2,800, which cannot be got at. Present indorsements are only $35,000.

He further said that the company was not applying net revenues to the purchase of the company's bonds but the proceeds of assets sold. He thought that considerably over $1,000,000 of the bonds had been bought for the treasury. **CURRENT REVENUES WERE USED IN THE BUSINESS.**

The "profits" are all needed in the business. Electricity said this three weeks ago, and we never make a mistake.

The statement mentioned above as to the retirement of bonds not out of profits but out of assets sold was made to the financial editor of the Boston *Herald* by a director of the G. E. Company who knows what he is talking about, two weeks after Electricity published the fact.

Where Will the Proceeds Go?

To Retire Bonds, We Guess.

It is reported in our news columns this week that Messrs. Tucker, Anthony & Co., of Boston, have purchased of the General Electric Company the Macon Consolidated Street Railway system.

This is one of the properties grouped together in the last G. E. report, par value, $3,860,338.33, carried at $4,766.75.

(From the Boston News-Bureau.)

The General Electric has bought in another $100,000 of its bonds and has now on hand between $1,100,000 and $1,200,000 of its own bonds.

From whom does the company buy these bonds?

Who are the brokers?

How much regular commission do they get?

What do the brokers pay?

How large are their shavings?

Why are bids not invited in regular and legal manner?

(From the Commercial Advertiser.)

The statement is made by an official of the company that the earnings during the year just closing would have been sufficient to pay something like 4 per cent on the stock.

Four per cent. of $34,711,600.00 is $1,388,464.00. If this has been earned, where is it? It is not in the treasury. There was only $744,000 of floating debt January 31, 1894. Where have the proceeds of notes collected disappeared to?

VANISHING ASSETS.

The Thomson Regulator patent, declared void last week by Judge Grosscup in Chicago, was carried on the G. E. books as worth $2,000,000 of the $8,000,000 of patent assets which they claimed in April.

The feeder and main patent was valued at about the same figure, and this was declared void in the U. S. Circuit Court at Philadelphia some months ago.

The lamp patent, $3,000,000 more, expired in November.

There now remains only the three-wire patent, which no one needs to use.

What are the patent assets carried at now ?

Is Mr. Ord scratching his head while pondering on this subject ?

The Electropoise.

An Honest Religious Journal.

The "Christian Advocate's" Position Clearly Stated.

(From the Christian Advocate, Jan. 17.)

REFUSED—AND WHY.

Electricity, of this city, is carrying on with vigor and every appearance of thoroughness the exposure of what it calls "a fraud,' "an outrageous humbug," "a swindling scheme," "a nefarious enterprise," "a worthless device," "an arrant fraud," "a cheat," "worse than the Louisiana Lottery." It publishes an analysis of it, and specifies what it declares to be five fraudulent claims.

Its proceedings would not have demanded notice from us if among its list of religious papers condemned for advertising it we had not seen the *Sunday School Times* and the *Christian Advocate*. As we should have been greatly ashamed if the charge had been true, and, knowing it to be false, we delayed for a week or two to see whether Electricity would retract it.

In the next number it published a card from Dr. Trumbull containing this sentence :

> The *Sunday School Times* rejected the advertisement of the [here the name of the trap is given] before the members of the electrical profession seemed to be aware of its unsavory nature.

Electricity humbly apologized for the error and accounted for it by stating that

> when we prepared our article we were informed by the editor of the *Christian Nation* that he had accepted the advertisement because it had been investigated and accepted by the *Sunday School Times* and that their acceptance of it was sufficient warrant for him.

Meanwhile we had written a note to the editor:

> We hereby inform you that the *Christian Advocate* did not publish that advertisement. It was offered to the paper, but when shown by the advertising agent to the editor it was rejected on the ground that it was a transparent humbug.

Electricity published the note, and accounted for supposing that it was advertised in the *Christian Advocate* by the fact that a person connected with this paper had signed an extravagant recommendation of the thing, and then says :

> It thus seems that there is a wicked partner in the joys and sorrows of the *Christian Advocate* editorial staff. The wicked partner indorses most fully [here the name of the trap is given] over his own name, etc.

There is but one authority who decides what advertisements shall be admitted to the *Christian Advocate*, namely, the editor. Because any person who gives the whole or a part of his time to editorial work on the *Christian Advocate* happens to recommend an unworthy article, to assert without investigation that the same was advertised in the *Christian Advocate*, is a carelessness which a paper engaged in exposures should be above.

At the same time Electricity has honorably given the retraction due publicity.

We do not employ persons because of their opinions upon outside matters. A man may be an allopath, homeopath, hydropath, an eclectic, a vegetarian, be deluded by one or many forms of quackery, or certify that a horse chestnut carried in his pocket cured him of rheumatism; he may be a Prohibitionist, a Republican or a Democrat in politics; he may favor woman suffrage or oppose it; if he is of good character, and does his work satisfactorily, it is all that is required of him.

[We are only too glad to give publicity to this statement of the *Christian Advocate's* position, for it goes a long way toward setting it right before the public. What the editor says as regards his indifference to the tenets of his employees is all right so long as those tenets are not given the appearance of authority by the use of the paper's name in connection with the holders of those beliefs. As it is, Dr. DePuy's name is not mentioned in connection with the Electropoise except as the editor or assistant editor of the *Advocate*. In this way a scandal has been brought upon the good name of the paper, and while the *Christian Advocate* need not concern itself, perhaps, with the personal opinions of its employees, it seems to us that it should be a matter of great concern if those opinions are hawked abroad in such close connection with the paper's name as to seemingly identify the individual and the paper. However great an offence against good taste (to use a very mild expression) it is for Dr. DePuy to seek notoriety in the way he is doing, it would be a matter simply between himself and his conscience if he appeared as an individual only. But when the initials D. D. are used in connection with his name it creates in the minds of the unreasoning a scandal upon the church, and when "assistant editor of the *Christian Advocate*" is also added it implies a responsibility that a paper jealous of its good name can ill-afford to shoulder. We have always believed and are glad to believe that the *Advocate's* skirts are entirely clean, but its name is constantly being used in a way to bring discredit not only upon itself but upon the cause it so ably espouses.—Ed.]

LEGAL NOTES.

In the suit between the Homestead Street Railway Company and the Pittsburg and Homestead Railway Company, Judge Green, of the Pennsylvania Supreme Court, has rendered a decision adverse to the former company, holding that under the law for the incorporation of street railways there can be but one street railway franchise over the same highway. The Pittsburg and Homestead Railway Company, having had a prior charter and right of way granted, has the sole right over the road in question, and the grant to the Homestead Company was a void act.

Suits have been filed in the U. S. District Court at Knoxville, Tenn., against the Knoxville Electric Street Railway by the Union Trust Company of New York and the Thomson-Houston Company of Massachusetts. The plaintiffs seek to foreclose the mortgages and have the road sold. The road has been in the hands of a receiver for nearly three years.

Judgment Against G. E.

The General Electric Company has been assessed $5,000 damages by a jury in the Supreme Court, New York City, before Judge Beach. The plaintiff was George R. Burke, suing as administrator of the estate of his son, Carl Burke.

Carl Burke was in the employ of the Ringler Brewery several years ago. The Edison General Electric Company was putting a plant in the brewery. While the company's employees were rolling an engine into the place one of the rollers slipped from under a plank and fell down into the basement. It struck Burke, who happened to be passing, and caused his death.

Popular Electrical Science.

IX.

The Magneto Telephone—Plain Directions How to Construct at Small Expense a Most Serviceable Instrument for the Residence or Office—The Days of Speaking Tubes are Past.

BY NELSON W. PERRY, E.M.

Thus far I have described only the magneto-telephone whereby the magnetic and electrical oscillations or waves are caused solely by the vibration of an iron armature in front of a permanent magnet around the pole or poles of which are wound coils of insulated wire forming part of the transmission circuit. With this no battery is required, and for short distances it is superior to the battery telephone (to be described later) on account of its greater simplicity and the almost impossible contingency of its getting out of order. The magneto instrument, therefore, is peculiarly adaptable for house use and for connecting together the different parts or departments of a large manufacturing establishment. It may also be used to good advantage over greater distances if specially wound for such service. In fact conversation has been carried on successfully by means of magneto instruments between New York and Cleveland, and circuits 15 to 20 miles long were at one time not uncommon. The first telephone exchange in Boston was for several years operated entirely with these instruments, and for some time after the first introduction of the telephone the magneto instrument was the only one in use anywhere. The battery telephone has some advantages which will be referred to later, but the magneto, by reason of its all but indestructibility, is pre eminently the private line instrument.

To enable any of my readers to construct a serviceable instrument of this kind I append the following instructions :

Buy of some optician or electrical supply house a small permanent horseshoe magnet about 2½ inches long. This should cost at retail not over 10 cents. Have two holes bored clear through both of the poles, leaving enough metal around them so that the steel will not be materially weakened. In having these holes drilled do not permit the steel to be heated for the purpose of facilitating the drilling, for if the temper be drawn the magnetism of the magnet will be destroyed and the usefulness of the magnet for the purpose greatly impaired. Next cut off two pieces of soft iron wire—the softer the better—about $\frac{3}{16}$ inch in diameter, and $\frac{7}{16}$ inch long. Turn down one end of each of these pieces so as to make a tight fit into the holes drilled in the magnet (*A B*, Fig. 1), and drive them home as shown in Fig. 2.

The reason for making these pole pieces (*A B*, Figs. 1 and 2) of soft iron is that the latter is much more sensitive to changing magnetizing influences than hardened steel, and it has been pointed out that the operation of the telephone is dependent upon these rapid changes for its efficacy. When these soft iron pole pieces are inserted they will be found to be strongly magnetized by their contact with the permanent magnet.

Next buy a spool of cotton-insulated copper wire of No. 32 gauge or smaller. An eight-ounce spool, which will contain enough wire to wind telephones for the whole neighborhood, can be had at retail for 60 cents or less.

This may be wound directly on the cores *A* and *B*, but it will be found more convenient to wind the coils on shallow spools first and then slip these over, as shown in Fig. 3. These spools may be conveniently prepared and wound as follows: Whittle down a pine stick to about the diameter of the cores *A B* or a trifle larger and wrap on this two or three turns of dry manilla paper cut into a strip, say about an inch wide. Cut out of pasteboard four disks, and, perforating their centers, force two of them on to the paper-covered stick, leaving a space between them of about quarter of an inch to hold the wire. Now, after slitting the portions of the paper cylinder which extend on either side beyond these washers, turn up the paper and paste it to the outside surfaces of the disks or washers, and one spool is complete. The other two washers will be used for the second spool.

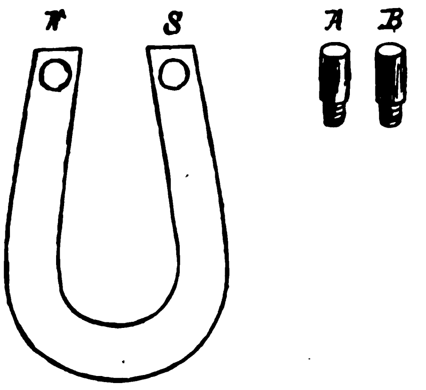

FIG. 1.

Before removing the spool from the stick it will be best to wind it full of wire. To start the coil, bore a small hole in the side of the spool and draw through this two or three inches of the wire to facilitate connections, and then wind on as evenly and tightly as possible, say 300 turns of wire, and end it off as it was begun, by pulling through another perforation three or four inches of the wire. It matters not in which direction the winding is done, but to avoid confusion and for convenience we will assume that while holding the stick in the left hand we have wound the wire from beneath over the spool or in the direction of the motion of the hands of a clock. Mark the side of the spool next to the left hand *a* and that nearest to the right hand *b*, for convenience of reference. The spool with its coil may now be transferred from the stick to the core *A*. Prepare and wind the second spool in an exactly similar manner and with the same number of turns of wire, and mark the side next the left hand *c* and the opposite side *d*. Now a little care must be observed in slipping this second spool onto its core to have it right, for if it is put on the wrong way it will not work. Let us suppose that in putting the first spool on core *A* the side *a* came next to the magnet, then in placing the second spool on *B* the side *d* must come next the magnet. Connect the *last* end of coil *A* to the *beginning* of coil *B* by removing an inch of the insulation and twisting the two tightly together.

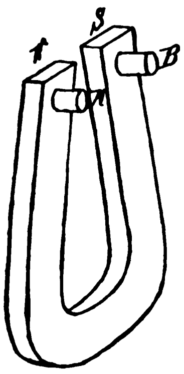

FIG. 2.

The next step will be to go to a wood turner and have the boxes made to receive this apparatus. The boxes should be cylindrical in form and about $2\frac{1}{4}$ inches in diameter. They should be made of some highly seasoned, close-grained hard wood, such as ash or maple or boxwood, or preferably of guttapercha. The box will be in two parts—a body *M* and a cover *L*, as shown in section in Fig. 4 and in perspective in Fig. 5. The face of the body should be turned down to a true plane first and then recessed $\frac{1}{16}$ inch deeper through a circular area of $1\frac{3}{4}$ inches, leaving an annular seat for the diaphragm and the cover. The center of the block should then be gonged out, as shown, to make room for the bobbins or spools *C C′*. The back of the body will then be cut or recessed so that the magnet without the spools may be introduced and fastened in position so that the pole pieces *A B* will come as near the center as possible. The face of the pole pieces should be just far enough below the face of the box so that the metal diaphragm when placed in position will just clear it. In order that the distance between the pole pieces and the diaphragm may be adjustable it may be well before putting the magnet in its seat to place therein a strip of indiarubber as a cushion which will hold the pole pieces normally a little too far away from the diaphragm; then by means of a set screw in the back of the box, as shown in Fig. 6, the adjustment may be readily made.

After the magnet has been placed in position, the spaces cut away to permit of its introduction should be filled in by tightly fitting pieces of wood coming flush with the surface, and then, for the sake of appearances as well as to make the box tight, it should be neatly covered with paper.

The lid should be of the same diameter as the box, having a hole about $\frac{3}{8}$ inch in diameter cut through its center and the space around it cut away so as to form a bell or trumpet-shaped section for the concentration of the sound waves. On the under side the cover should be cut away $\frac{1}{16}$ inch except around the edges, as shown in Fig. 4, so that when the diaphragm is in place and the lid fastened on, the diaphragm will be tightly gripped around its circumference but will be free to vibrate in other parts.

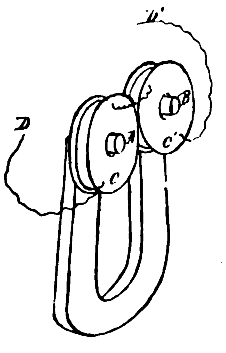

FIG. 3.

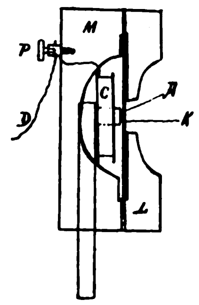

FIG. 4.

For the diaphragm, buy a sheet of ferrotype plate of any photographic supply dealer. This is the material upon which ferrotypes are taken and will cost five or ten cents. One plate will be sufficient for a dozen and a half or more diaphragms.

With a pair of compasses strike out a circle 2 inches in diameter on cardboard; cut this out and using it as a template scratch out similar circles on the ferrotype plate with a pinpoint and cut these out with a pair of scissors. It is best not to strike these circles directly on the ferrotype plate with the compasses for fear of indenting it, but it may be done with care.

Place the diaphragm centrally on the body of the box and then screw the cover down upon it lightly, taking care that the screws do not touch the diaphragm.

But previous to this place the spools upon the magnet pole pieces—bore two small holes through the back of the box through which the ends of the coils may be carried. Screw in a couple of small binding posts and attach each wire to one of these, as shown in Fig 4.

This instrument may be used equally well either as a transmitter or as a receiver, and it will be found a great convenience to make two of them for each station so that one can be held continuously to the ear while the other is used as a transmitter.

The method of connecting up two instruments is shown in diagram, Fig. 7, and the method of connecting up four—in case there are two instruments at each station, one to be used as a receiver and the other as a transmitter—is shown in Fig. 8. The binding posts *A* and *B* are those connected with the coils on pole pieces *A* and *B*. It will be observed that in all cases an *A* binding post is connected with a *B* binding post, and this rule will hold good however many instruments there may be in circuit. Nor does it matter, in Fig. 8, which one of the two instruments is used as a transmitter and which as a receiver, for these instruments are perfectly reversible.

In Fig. 6 are given two views of the instrument—the one to the left being a section through the axis and the one to the right a rear view, showing the parts cut away for the admission of the magnet, similar parts being numbered alike in both. *C* is the set screw for adjusting the position of the magnet with reference to the diaphragm. *D* is a bar of brass or other non-magnetic material laid across the magnet upon which the point of the set screw rests. The solid black portions shown most plainly in the left hand figure are pieces of rubber or elastic cushions intended to permit of a motion of the magnet towards or away from the diaphragm as the set screw *C* is screwed in or out.

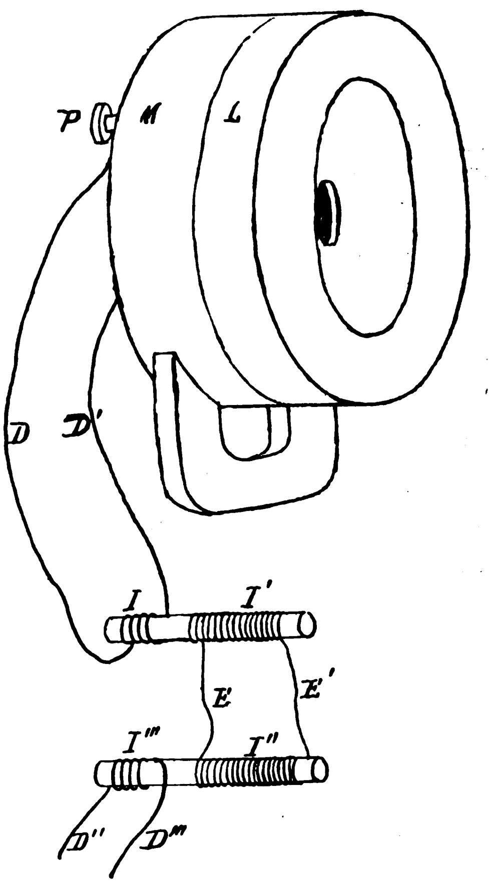

FIG. 5.

In Fig. 5, at the lower portion, I have illustrated two induction coils, such as are frequently used in long distance telephone service. They are not much used with magneto instruments and do not necessarily concern us just now, but may just as well be explained here as elsewhere.

THE TELEPHONE INDUCTION COIL.

I have already explained in a previous article how an alternating or variable current in a wire sends out etheric waves in all directions, which in turn set up similar alternating currents in other conductors with which they come in contact. I have also stated that the ether resident in iron propagates these waves with enormously greater facility than does the ether in other substances, and pointed out that when we want to transmit energy from one coil to another by means of these ethereal undulations by far the best method is to place both coils on a core of iron. Such an arrangement is the ordinary induction coil.

Now, electrical energy is composed of two distinct factors, just as is the energy of running water.

We have not defined a waterfall when we have stated that it is 100 feet high or that 1,000 gallons of water per minute is flowing. When we state, however, that a given stream pours 1,000 gallons of water per minute in a fall of 100 feet the rate of expenditure of energy in that waterfall has been clearly defined—it will be equal to the weight of the water flowing in 1 minute multiplied by the height of the fall. Assuming that a gallon of water weighs 8 pounds, 1,000 gallons will weigh 8,000 pounds, and if this weight of water falls 100 feet, it will develop 100 × 8.000 = 800,000 foot pounds of energy. If this amount of energy is developed in 1 minute, then the horse-power developed will be $\frac{800000}{33000} = 24\frac{8}{33}$ horse-power. The same energy would be developed if half the amount of water fell double the distance or double the amount fell half the distance.

In electricity the situation is very analogous. An electrical energy is not defined when we say that it flows under a pressure of a given number of volts, nor when we say it delivers so many amperes. But when we say, for instance, that in a given circuit the pressure is 100 volts and the current delivered is 10 amperes, the amount of energy or its capacity to do work is clearly defined and is equal to 100 × 10 = 1,000 watts; 746 watts equal a horse-power, so that by dividing 1,000 by 746 we get the value of that current in horse-power. But it is clearly the same so far as the energy of the current is concerned if we have 100 amperes flowing at 10 volts, 1,000 amperes at 1 volt or 1 ampere at 1,000 volts, provided the product of the amperes and volts remains as before, 1,000. It does make a good deal of difference, however, when we come to transmit this energy, whether it is 1 ampere at 1,000 volts or 1,000 amperes at 1 volt—it being very far preferable in all cases of transmission to have the voltage factor large and the ampere factor small than the reverse. The induction coil gives us a very simple means of changing a current of low voltage to an equivalent one of high voltage, and vice versa. Thus if the circuit from our telephone is wrapped say four times around an iron bar, and there be another circuit wrapped the same number of times around the same bar, there will be induced in that second circuit a current having the same number of amperes and at the same number of volts as the first. If the number of turns in the second coil be twice as many as those in the first or primary coil, the current induced in the second will be only half as great, but its voltage will be twice as high, so for transmission purposes we may by means of the induction coil transform our energy up to any voltage desired by simply putting on enough turns of wire in the secondary. The amperes will of course be correspondingly reduced. This operation is perfectly reversible, so that if the transmitted high voltage current be made to pass through a coil of many turns at the further end, it may be transformed down again to any voltage desired. Now; as before intimated, high voltage currents are preferable for transmission purposes; so where long distances are concerned it is usual, especially in battery telephones, to employ induction coils for the purpose of raising the voltage of the telephone currents. In Fig. 5 the method of doing this is diagrammatically shown. The current from the telephone is connected to a few turns of comparatively large wire *I* on a soft iron bar or core. *I'* is a coil of many turns of fine wire on the same bar. Usually one of these coils is wound directly over the other. The comparatively low potential currents in *I* induce equivalent currents of high potential in *I'*. At the distant point is another induction coil, *I'' I'''*. The high potential currents induced in I' in passing through the many convolutions of *I''* induce in *I'''* equivalent currents of low potential, and in this latter circuit is placed the receiver of the distant station.

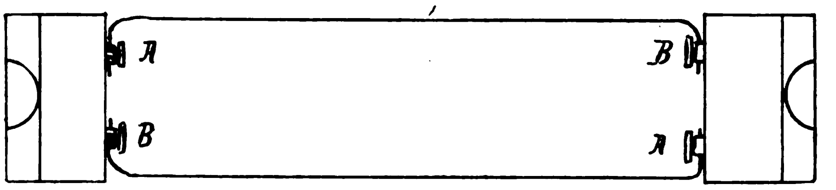

FIG. 7.

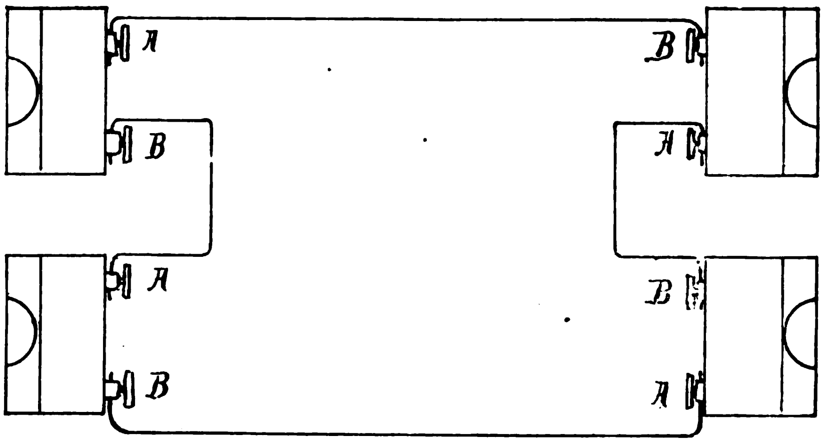

FIG. 8.

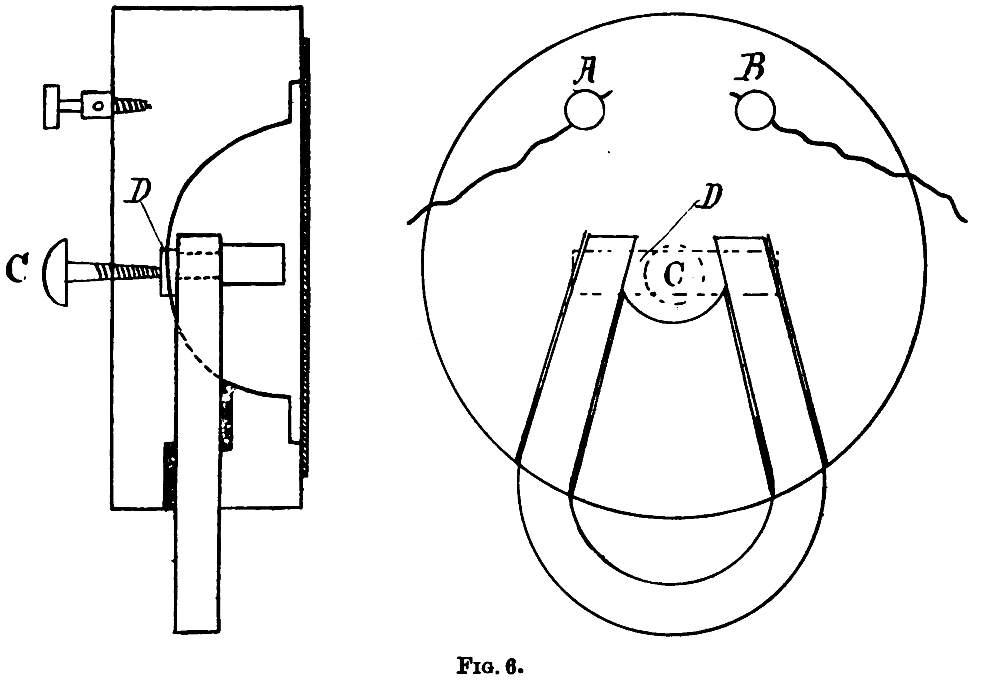

FIG. 6.

In my next article I propose to describe the microphone and battery transmitters.

Messrs. T. D. F. Andrews & Co., of London, England, have made some experiments upon the inductance of sheathed cables. The results show that, whether the sheath or outer concentric covering be of iron or copper, the inductance is practically the same; and if an ordinary copper concentric cable be used in place of the iron armored cable of the same cross section, the results are the same in every case. This is interesting so far as it goes, but a little information regarding the periodicity at which the tests were made would add to the value of these observations.

A remarkable experiment has just been made near Orange, N. J., on the Eagle Rock line of the Suburban Traction Company with some magnetic sand from the ore-separating works of Thomas A. Edison at Ogden. Mr. Edison had the idea that the sand would have more effect in preventing slipping of the wheels than the ordinary sand. The experiment was tried during the snow storm on the Eagle Rock line, where the grades are excessive and the difficulties of operating in the snow are enormous. The experiment proved a complete success, the sand making a perfect electrical connection with the rails and no slip being noted.

One of the most elevated telegraph lines in the world is that reported from India. On the Gilgit line two passes have to be crossed, one 11,600 ft. high and the other 13,500. The snow often lies at a depth of from 10 to 18 ft., and the poles used are 30 ft. long. The poles are planted close together. Offices of observation are close by, in each of which two Europeans are stationed, leading a life in comparison with which that spent at submarine cable stations is riotous and crowded. Many months the passes are cut off from mankind by the snow blockade.

The first sailing vessel to be lighted by electricity is said to have been the Spanish bark La Vigusea, a bulk-oil and general cargo carrier. She is fitted throughout with incandescent lights, the power for the dynamo being furnished by a small oil engine, which also furnishes power to pump her oil cargo when she is loading or unloading.

PRE-SCIENTIFIC ELECTRICITY.*

BY HORACE HAYDEN, JR.

The electricity of to-day and that of the future have been the subject-matter of many recent articles. In fact, the general reader should now be well acquainted with what has been accomplished in this science during a period of less than three hundred years, and must readily apprehend that more wonderful things will yet be achieved. Why all this has not been effected earlier is a problem which we shall attempt to solve, and which may prove to be interesting to those that care to accompany us over the period when this wonderful force played a part in the life of man in strong contrast to its obedient servility of the present day.

Classical scholars are familiar with the superstitious reverence the Greeks had for amber, and the tendency among them to use the word *electron* (*ἤλεχτρον*)—which is the Greek word for amber—just as the word *adamant* was frequently used as designating some ideal, some imperfectly known substance, possessed of almost miraculous properties. The Greeks even thought that the yellow semi-pellucid substance lived and had a soul, for, when excited, it seemed to become animated in its attraction for small particles that came within its influence. The name itself appears to have been derived from this physical myth, *Elector* (*Ηλέχτωρ*) being one of the names of the sun-god.

In the twilight of legendary Greece, we find that familiar and beautiful myth of Phaethon, son of Phœbus Apollo, who rashly undertook to drive the solar chariot through the heavens. We all remember how the chariot approached so near the earth that the mountains began to blaze, and rivers and fountains dried up, and that Zeus, enraged, hurled his thunderbolt, thereby precipitating the charioteer into the River Eridanus. There he was found by his sisters, the Heliades, who, lamenting long and bitterly, were at last changed by the gods into ever-sighing poplars, and their tears, which continued to flow, became translucent amber as they dropped into the stream.

The Greeks, even at this remote period, thus revealed their knowledge of the origin of amber. The tears of the ever-sighing poplars, becoming amber as they dropped into the stream, is but a poetic way of expressing the fact that amber is the resinous exudation of trees that becomes fossilized by the action of the water.

Without much effort of imagination it is possible to trace this chain of analogies a step farther. The myth of Zeus's thunderbolt—which we know to be synonymous with the lightning stroke—seems related to the properties of amber. By exciting amber it is possible to produce miniature lightning, and it is more than probable that the Greeks made this comparison. If the *Electra* (*Ηλέχτρα*) of these legends—who, we will remember, was the goddess of brightness—is, as has been pointed out, the personification of lightning, the comparison would then seem almost certain, for the resemblance between the names *Electra* and *electron* cannot be accidental.

Amber was highly prized by the Greeks as an amulet, and was precious as an article of jewelry. This we perceive in the Odyssey, when the Phœnician traders offer to the Queen of Syra "a gold necklace hung with amber." And thus, being constantly worn, the friction of garments would often excite sufficient electricity to cause it to attract, as Pliny remarks, "the fine threads of fringe" and other small particles, a remarkable fact which was very likely to be noticed by the wearer.

Thales was the earliest philosopher that made direct mention of this property of amber, and is, therefore, too often credited with the original discovery. He appears to have regarded the entire world in the light of a living being, gradually maturing and forming itself from water, the imperfect seed-state. This view endues the universe with vitality, and considers the world as a mere spontaneous development of a pre-existing germ of life. Thus he is said to have looked upon the apparently dead as animated and ensouled; and, hence, taught that amber and the magnet possess a living soul, from which their power of attraction is derived.

The adamant or magnet—to which the Greeks compare amber, although they knew it to differ from the latter in its attractive properties being inherent and only exercised upon iron—was originally found near the town of Magnesia, in Lydia, and from this circumstance was called *magnes* (*μάγνης*), from which the present name is derived. Plato tells us, in the "Ion," that it received this name from Euripides, but by the people was called the Heraclea stone. He adds, "for not only does this stone possess the power of attracting iron rings, but it can communicate to them the power of attracting other rings; so that you may see sometimes a long chain of rings and other iron substances, attached and suspended one to the other by this influence."

Here we clearly see that he had observed the power of the magnet to impart its magnetism to other pieces of iron; but, without better authority than we have, it would be imprudent confidently to assert, as others have recklessly done, that the ancients had any definite conception of the polarity of electricity or of magnetism.

Their deficiency in positive experimental knowledge, however, was abundantly replaced by prolific powers of imagination. They have told us that the magnet would attract both wood and flesh; that by holding a magnet in the hand we might find relief from both gout and convulsions; that its effect on the brain causes melancholy; that it acts as a love philter; that its power is lost after being rubbed with garlic, but may be restored by a treatment with goat's blood; and that it has no power in the presence of the diamond. All which assertions, and many more, were eagerly grasped by the wonder-loving writers of the Middle Ages.

It seems impossible to determine whether the Europeans themselves discovered that a suspended magnet will lie in the direction of the magnetic medium, or whether they received this knowledge through the Arabs, who, in turn, received it from the Chinese; for the latter claim as early as the sixty-fourth year of the reign of Ho-ang ti (2634 B. C.) to have been acquainted with this property of the magnet. After this fact became known in Europe, the magnet evidently took the name of lodestone (leading-stone), a name used by early writers; although we find no record of the mariner's compass until some centuries later.

If, now, we follow the Greeks into Egypt, our attention is attracted by the singular proposal of Dinocrates, the great architect and designer of Alexandria, to construct the arched roof of the temple of Arsinoë entirely of magnetic material, so that the iron statue of the princess might float unsuspended within the temple. But before the work was finished he died, as did Ptolemy Philadelphus, who had ordered the temple to be built in honor of Arsinoë, his sister and queen.

We have considered at some length the knowledge which the Greeks possessed of the electrical property of amber and the attractive power of the magnet, and must now pass rapidly over their acquaintance with the more familiar phenomena of atmospheric electricity.

The electricity of the earth usually concentrates itself in sharp mountain peaks, the natural dischargers of the planet, but sometimes will flow from smaller objects resting on the earth and projecting into the air. Some years ago Dr. Werner von Siemens, the noted physicist, while on the top of the pyramid of Cheops, at Gizeh, during a storm, perceived that a flow of electricity escaped from his finger when extended toward the heavens. The current manifested itself powerfully enough to cause a loud hissing noise, and from the metallic button of his gourd he obtained electric sparks.

Scholars have told us that the word *pyramid* is derived from the Greek root *pyr* (*πυρ*), which means fire; and add, that this name was chosen to indicate that pyramids terminate in a point, in the shape of a flame. If this be the correct derivation of the word, it seems more logical to agree with Fonvielle, that at some time in the many centuries during which the pyramids stood before the Christian era these mountains of stone had been seen crowned with flame—illuminated by the energies of the earth; but this is mere conjecture, and the most recent authorities maintain that the word *pyramid* is a derivative from the Egyptian word *pir-em us*, which means perpendicular height.

The manifestation of this form of atmospheric electricity is usually in the shape of a brush or a star of light. The records of the display of these lambent flames have accumulated with years, and are found in the literature of all languages, and of every age and country.

Among the ancients they were distinguished as Castor and Pollux, the favorite sons of Jove, who watched over the games, and also over travelers, especially those following the sea. The Dioscuri are represented on ancient coins as equestrians with a star floating over the helmet of each, and between them a zigzag line that Prof. Schweigger deems a representation of an electrical spark.

In modern times, around the Mediterranean, these electrical displays have been hailed as the light of St. Clair, St. Nicolas, St. Helena; elsewhere they have had the appellation St. Barbe and St. Elmo. The Portuguese call them Corpo Santo and the English, Comazants. Even at the present day of enlightenment, sailors attach a certain importance to these signs; for they suppose that the apparition of one of these natural lights portends that the severest part of the storm has yet to come, while two of them at once indicate a cessation of the tempest. In all of this we trace an inheritance from antiquity; Pliny, in fact, telling us that these lights are dangerous and unlucky when coming alone, but when two come together they bring comfort and foretell a prosperous voyage and chase away that "dreadful, cursed, and threatening meteor, Hellena." Thereupon, men at sea invocated the gods Castor and Pollux.

In the conception of Castor and Pollux we at once see the evidence of a predominant facility to seize the passing event, and a sensibility wonderingly alive to all the phenomena of nature. Thus, the ancient historians, with this characteristic facility, never omit to mention, with minute care, the phenomena arising from this natural electricity.

Seneca relates, as a strangely significant warning to Gylippus, that a star came and hovered over the shield of that general as he was sailing to Syracuse.

Plutarch, after speaking of the great victory of Lysander—which finished in one hour a war that had been protracted in its continuance—records: "Some, therefore, looked upon the result as a divine intervention, and there were certain who affirmed that the stars Castor and Pollux were seen on each side of Lysander's ship, when he first set sail from the haven toward his enemies, shining about the helm; and some say the stone which fell down was a sign of the great slaughter."

---

* The *New Science Review.*

"The foremost man of all the world," intellectually distinguished by extraordinary genius in diversified pursuits, we must acknowledge to have been a strong-minded man, yet Cæsar does not neglect to inform us that the spears of the fifth legion appeared on fire during the African campaign; Castor and Pollux thus announcing that he would soon disperse the remainder of the Pompeian party. Another instance was the fire seen around the head of Ascanius.

We now turn our attention to that other form of atmospheric electricity, dignified by the ancients as the thunderbolt of Jupiter. Some of our modern authors, and others more zealous than wise, would have us believe that if Franklin did not actually appropriate the idea of others, his experiment was, in fact, anticipated by the ancients thousands of years before.

Herodotus, one of their authorities for this assumption, says: "The Thracians, when it lightnings and thunders, let fly their arrows toward the heavens, uttering threats against the god, for they do not believe there is any god but their own." It is quite evident that the Father of History does not intend to have us understand that they thus shot their arrows for the purpose of withdrawing the electricity from the clouds, as these energetic authors would interpret.

The Etruscans, renowned in antiquity for their knowledge on this subject, are said to have been able to direct the lightning, but this was done by exorcisms and conjurations. Among the Romans, Numa, instructed by the nymph Egeria, succeeded in intoxicating Faunus and Picus—whose names in this place probably denote only the priests of these Etruscan divinities—and learned from them the secret of making, without danger, the thundering Jupiter descend upon earth, and immediately put it into execution. From that time Jupiter had the surname Elicius, or Jupiter who is made to descend, and was adored in Rome.

Tullus Hostilius, it seems, was less fortunate. "It is related," says Livy, "that this prince, in searching the memoirs left by Numa, found among them some instructions relative to the secret sacrifices offered to Jupiter Elicius. He attempted to repeat them, but in the preparation or celebration he deviated from the sacred rite. Exposed to the anger of Jupiter—evoked by a defective ceremony—he was struck by the lightning and burned, together with his palace."

Then there is the story of a medal whereon appears the temple of Juno, the roof of which is supplied with many pointed stakes, that some would have us believe to be lightning-rods. Another medal, described and engraved by Pellerin, shows the god Jupiter in a cloud, with the lightning in his hand, and below a man guiding a kite. But the authenticity of this medal is suspected.

Artaxerxes believed that two swords, planted in the ground, dispersed the thunder-clouds. In the time of Charlemagne, poles were used for the same purpose, but, unfortunately for those that would deprive Franklin of scientific renown, they were not supposed to have any efficacy until bits of magical paper had been stuck upon them.

The ancients also believed that lightning never fell except by the immediate interposition of the gods; and whatever thing or place it struck was ever after deemed sacred—consecrated by the Deity himself. The Greeks placed an urn over the spot where the lightning entered the earth, and the Romans had a similar observance. Herodotus tells us that when Scyles, who had studied the language and sciences of Greece, ascended the Scythian throne, it was his desire to be initiated into the mysteries of Bacchus, which was against the wish of his people; and as he was about to take some of the sacred utensils in his hands, his palace in the city of Borysthenites was totally demolished by a thunderbolt.

To imitate thunder and lightning was considered a sacrilege by all religions. We remember the exciting passage of Virgil, wherein the poet describes the infernal regions and the fate of Salmoneus. This prince, according the legend, wished to be called a god, and to receive divine honors from his subjects. Therefore, to imitate thunder, he used to drive his chariot over a brazen bridge; and to counterfeit lightning, he darted torches on every side. This impiety provoked Jupiter. Salmoneus was struck by a thunderbolt, and placed in the infernal regions near his brother Sisyphus.

Tacitus, the philosophic historian of the declining glories of Rome, addressed one of his most fearful reproaches to the Emperor Caligula for attempting to manufacture the lightning and thunder of the sovereign of men and gods. Not content with deafening his subjects by compelling them to listen to his artificial thunder, this refined tyrant—more ambitious still than Salmoneus—had constructed a machine calculated to reply to the gods, by throwing a heavy stone toward the sky whenever the lightning happened to strike the earth.

These few references, selected from the many accounts left us, will give an adequate idea of the superstitious respect entertained by the ancients for thunder and lightning. These superstitions may appear extremely ridiculous to us, but we should not overlook the fact that but a century ago Franklin found numerous opponents who agreed that it was as impious to erect rods to ward off Heaven's lightnings as for a child to ward off the chastening rod of its father.

Pliny leaves us the following remarkable explanation of why lightnings are attributed to Jupiter:

"Most men are ignorant of that secret, which, by close observation of the heavens, deep scholars and principal men of learning have found out, namely, that they are the fires of the uppermost planets which, falling to the earth, are called lightning; but those especially which are seated in the middle, that is about Jupiter, perhaps because participating in the excessive cold and moisture from the upper circle of Saturn, and the immoderate heat from Mars, that is next beneath, by this means he dischargeth the superfluity, and therefore it is commonly said, 'That Jupiter shooteth and darteth lightning.' Therefore, like as out of a burning piece of wood a coal flies forth with a crack, even so from a star is spit out, as it were, and voided forth this celestial fire, carrying with it presages of future things; so the heavens showeth divine operations, even in these parcels and portions which are rejected and cast away as superfluous. And this most commonly happens when the air is troubled, either because of the moisture that is gathered moves and stirs forward that abundance to fall, or else that it is disquieted with the birth, as it were, proceeding from a great bellied star, and therefore would be discharged of such excrements."

Nothing needs to be said about the state of science which this far from luminous exposition reflects.

The ancients were also acquainted with the torpedo, or fish of Jupiter, which is found in the Mediterranean, and has the faculty of accumulating, to a remarkable degree, animal electricity, with which it can give a powerful electric shock, whence the names of *Narce* (*νάρχη*—numbness) and *Torpedo* (*torpeo* quasi torpor) were given to it.

Professor Thompson has called attention to the interesting fact that the Arabian name for the torpedo, *ra-ad*, signifies lightning. Aristotle was acquainted with the fact that its benumbing power could be sent by the fish some distance through the water. Scribonius, Largus, Galen and Dioscorides speak of the local application of a living torpedo in headache and gout; and, as an article of food and medicine, the torpedo seems to have enjoyed considerable reputation among ancient epicures.

We take this opportunity to consider for a moment the Vestal Fire, inasmuch as Professor Schweigger has said that he believed it was electric, and has been quoted by others that appear to have made no research themselves. Yet to agree with Professor Schweigger we would have to deny the authenticity of many of the ancient writers, among them Livy and Plutarch. The latter, in his life of Numa—to whom is ascribed the introduction of the worship of Vesta in Rome—has gone into much detail, and informs us that it was provided that if at any time the Vestal Virgins should allow the sacred fire to go out they were to be severely punished, and the fire rekindled from the sun's rays brought to a focus by a concave mirror made of polished metal. Neither this nor the earlier method of obtaining the fire by means of the friction of dry sticks appears to have anything to do with electricity.

Lucretius, in his celebrated poem *De Rerum Natura*, takes up the subject of magnetism, and, after he has spoken of the chain of rings already mentioned by Plato, attempts to solve the mystery of this phenomenon. He imagines the magnet to radiate innumerable atoms in streams that rarefy the space between it and the attracted iron, into which space the iron is forced by the pressure of air from behind. And as the metal is compact in its elements, the particles thus streaming into the void drag with them the entire chain. The magnet does not attract other substances, for the reason that some are held fast by weight, as the ponderous gold; and some are of such attenuate consistency that they lend its waves no hold.

However remote from being correct, this is at least an attempt at a theory. And a century later Pliny records the fact, that rubbing the blade of a knife—which we suppose was hardened steel—with the lodestone would make of it a permanent magnet.

Amber was in such repute in Rome at this period that Pliny sarcastically remarks that the price of a small figure in it, however diminutive, exceeds that of a healthy slave or warrior.

"True it is," he goes on to say, "a collar of amber beads worn about the necks of young infants is a singular preservative to them against secret poisoning, and a counter-charm for witchcraft and sorceries." This superstition we have inherited, although the custom as now in vogue is not as a defence against witchcraft and sorceries, but as an amulet or prophylactic.

If we stop to reflect for a moment, we will see that these men—philosophers whose genius sounded the depths of the microcosm, and discovered moral truths by a sublime intuition—knew natural and physical truths more as matters of fact and observation than as determined by law. Pliny himself says: "Of all these things there is no certain reason to be given, but secret they must be, hidden within the majesty of nature, and reserved within her cabinet." Their knowledge could not be called a science, in the modern sense, unless indeed an occult science. The only attempt they appear to have made to generate electricity was the accidental discovery that amber, when rubbed, would attract small particles, and here the extent of their knowledge seems to have terminated. They have left no evidence of even an endeavor to learn the true cause of this phenomenon, which hence remained one of the "awful mysteries of nature."

So we pass into and through that long and sad intellectual darkness of the Middle Ages. The only step of importance in electrical science which we find recorded is the use of the mariner's compass in Europe, the earliest of which were made by floating a magnetic needle on a chip of wood in a basin of water.

During this long period, the human mind was undergoing an intellectual revolution. Christianity—a religion of love—had succeeded the ancient religion of superstitious fear of gods and of nature.

In the latter part of the Middle Ages—in that period styled the "Revival of Learning"—a taste for ancient classic literature arose, and was necessarily and promptly followed by the introduction of the "art preservative of all arts," that of printing. Like a second awakening, we find, in the sixteenth century, an intellectual condition that produced works which made immortal the names of Michel Angelo, Raphael, Titian, Albert Dürer, Holbein, Edmund Spencer, Shakespeare, Cervantes, Rabelais, Montaigne, Ariosto, Tasso, Copernicus, Galileo and others.

At the very end of that century, in the year 1600, Dr. William Gilbert, surgeon to Queen Elizabeth, and the most distinguished scientist in England, found this little seed of human knowledge in the archives where it had been buried for fifteen hundred years. He straightway planted it in rich loam when he published his famous book, *De Magnete*, in which he made known that the attractive property of amber when rubbed was not inherent in that substance alone, but that it also existed in some twenty other bodies, in which are included the precious stones, glass, sulphur, sealing-wax and resin. Inasmuch as all these substances acted like amber, Gilbert called them *electrics*, and called the phenomenon itself *electricity*; terms which he derived from *electron*.

The publication of Dr. Gilbert's work marks the true commencement of electrical science, its immediate effect everywhere having incited philosophers to efforts to extend his list of electrics.

The propagation of that little seed, though slow at first, has steadily advanced, until now we are reaping a rich and golden harvest. And for the foundation of it all we are indebted to Dr. William Gilbert, whose name should be immortalized as the Father of the Science of Electricity.

American Institute of Electrical Engineers.

The 93d meeting of the Institute was held at 12 West 31st street, New York, Wednesday evening, January 16, President Houston in the chair.

Prof. Macfarlane, of Ithaca, N. Y., read his paper "On the Units of Light and Radiation," which was discussed by Messrs. Kennelly, Wolcott and Burnett.

It was voted subsequently that the paper be referred to Committee on Units and Standards for consideration.

The paper by Mr. Alton D. Adams, of Boston, was read by the author and discussed by Messrs. Crocker, Richard Fleming, Sheldon, Ashley, Burke, Waldo, W. L. Bliss and Gano S. Dunn.

At the Council meeting in the afternoon the following associate members were elected: Henry S. Anderson, H. W. Buck, Edmund V. Cox, Sylvester P. Denison, Arthur J. Farnsworth, Burton S. Lanphear, Edward A. Leslie, William B. Lester John Clifford Rennard, Henry W. Fisher, Henry Leslie Friedenberg, Edward B. Gallaher and J. Henry Klinck.

The following associate members were transferred to membership: Peter Wright, Arthur V. Abbott, Louis B. Marks, Edward V. Baillard and Francis Broadnax.

Change of Offices.

The New York offices of the Electric Storage Battery Company of Philadelphia have been moved from 45 Broadway to the Manhattan Life Insurance Company's Building, 66 Broadway. The change was made to meet the increase of business of the company.

THE T.-H. REGULATOR PATENT.

Abstract of Judge Grosscup's Decision.

This is a suit for infringement of patent No. 238,315, granted to Elihu Thomson and Edwin J. Houston, March 1, 1881, for "current regulator for dynamo electric machines."

The claims of the patentees are for a combination and are expressed in the following terms:

"1. In a current regulator for a dynamo electric machine, the combination of a device responding to changes in the main or generated current, a shifting commutator for said machine, and mechanism controlled by said responsive device to shift the commutator to those positions where the current taken up by said commutator shall be constant.

"2. In a current regulator for a dynamo electric machine, an electro-magnetic device acted upon by variations in the main or generated current, an adjustable or shifting commutator for the machine, and mechanism controlled by said electro-magnetic device to adjust the commutator to those positions where the main or generated current taken up by said commutator shall be constant."

The principal defence is that, in view of the prior state of the art, and especially of the invention patented by Thomson and Houston, January 20, 1880, No. 223,659, this so-called invention has been anticipated, and the patent, therefore, is invalid. So far as I have been able to ascertain, all knowledge of electricity is, so far, purely empirical; and mere speculations, therefore, however acute and plausible as to the ways and methods of this force, are likely to be erroneous, and therefore valueless. In the view of the case to which my judgment has come, it is unnecessary to enter these regions of speculation, or attempt to decide between the respective contentions so earnestly put forth and learnedly maintained.

Patent 223,659 discloses a device almost identical with that of the patent in dispute. Whatever may be the cause of the sparking, it was then discovered or known by the patentees that a proper shifting of the brushes upon the commutator would bring about a condition of minimum sparking. But the position of the brushes upon the commutator to prevent sparking was not necessarily uniform. It depended upon the speed of the revolutions, which, in turn, was dependent upon the uniformity of power, not so easily obtainable then as now. It depended also upon the accidental or purposed introduction or withdrawal of resistance from the circuit. It is apparent that a shifting by hand to meet these varying conditions would be both cumbersome and unsatisfactory, and the invention subsequently patented as 223,659 was to meet these electrical difficulties.

The object here, as in the subsequent patent of Thomson and Houston, was to obtain a device that would move the brushes backward and forward responsively to the electrical condition that such movements were intended to meet. For this purpose, the patentees employed a mechanical device, in every substantial respect like that described in the patent in suit, except that the electro-magnet was put in the short circuit beginning with the forward member of one of the brushes and ending in the main circuit at the rear of the other member of the brush, instead of having been put in the main circuit, as in the patent in suit.

It may be admitted that the anti-sparking device is, in some respects, different from the one in suit. The question is, whether the difference is one of principle and conception or only such difference in use as leaves the uses, nevertheless, analogous.

The complainants' anti-sparking patent revealed to the public a device by which the brush on the commutator could be automatically changed forward and backward responsively to a change in the current of electricity. The device, it may be admitted, was only used to prevent sparking, and was only acted upon by a small portion of the current, but it disclosed clearly and for all purposes a mechanism that would rock the brushes responsively to changes in the current, irrespective of whether such currents were the main or only accessory ones. The problem sought to be solved by the patent in suit was a somewhat different one in its ultimate ends, but the object of both patents was reached by the application of any principle, and the use of any device, that would automatically maintain constancy of current, notwithstanding changes of motive power or of resistance. The fact that one may be intended to prevent destructive effects upon the machine itself, and the other to adapt the machine to the circumstances of changing resistance, will not make both devices patentable if they employ substantially the same principles and the same mechanism. The immediate objects in view were thus analogous, and the ultimate uses into which they were diverged do not make them less so.

It must be remembered that it was then well known to electricians that the shifting of the brushes forward and backward upon the commutator increased and diminished the volume of the current, and thus equalized it against the tendencies of a changed resistance. This is what the anti-sparking invention accomplished automatically within narrow limits. It is what the so-called invention in suit accomplished automatically through a wider scope. There was required simply experimentation to determine its adaptability to the new purpose. Doubtless, such experimentation was difficult and delicate, and called into exercise a multitude of different adjustments of the brushes. But, it was all done in the light and along the lines of the earlier device and of electrical principles well known to the public. It was in my mind adjustment purely, and not a new conception of either a principle of electricity or a mechanism to carry it out. If there is any mistake in this judgment it is, I think, in putting a higher estimate upon mechanical skill in electrical fields than is applied to other fields, but I do not see how this can or ought to be avoided. No new distinct conception or discovery ought practically to go unrewarded. But it certainly would if its readaptations by experiment or adjustment to the thousand uses the field of electricity discloses were to be regarded as patentable improvements. I differ from Judge Colt in this case with reluctance, for I defer to his superior experience and wisdom in the patent field, but I cannot follow him in this case without violating my own sense of judicial responsibility.

The bill will be dismissed.

Phœnix Telephone Co. in Indianapolis.

The agents of the Phœnix Telephone Company report as a result of their canvass of the city of Indianapolis that 1,500 subscribers have been secured and that only 300 more names will have to be listed before the company applies for a franchise and establishes an exchange. The new company's rates for service are placed at $36 for business telephones and $25 for residences, and this rate will remain unchangeable between all points within the city limits. The charges of the old company are $48 for business telephones and $36 for telephones in residences.

Herrick & Burke.

The above is the title of a newly founded copartnership located at 203 Broadway as consulting and supervising engineers. Mr. A. B. Herrick and Mr. James Burke are the members, and are both well known.

COMMUNICATION.

The La Roche Assignment.

To the Editor of ELECTRICITY.

DEAR SIR: You have no doubt received notice from J. Franklin Stevens, who has been appointed assignee of La Roche Electric Works, Incor., that it was deemed expedient for our company to liquidate as a corporation while still solvent, the primary reasons for this step being the extreme difficulty in making collections and the closeness of the money market.

The officers and directors of the company have at different times advanced money to the company, but as you will note by the assignment report, no preferences were given even to ourselves. As stated in this report, there are ample assets in hand to satisfy every one concerned.

The writer has associated with himself certain gentlemen of financial means and proposes to continue the manufacture of the well-known La Roche apparatus with increased facilities. He will in all probability, when an appraisement is made, purchase the entire equipment of the La Roche Electric Works, and for the present continue manufacturing in the same building until more commodious quarters can be obtained.

Thanking you for any courtesies you may extend to the firm, I remain very truly yours,

F. A. LA ROCHE.

Philadelphia, January 19, 1895.

It was with considerable regret that we learned of the difficulties of the La Roche Company. In the new venture which is planned Mr. La Roche and his associates will have the best wishes of ELECTRICITY and of the entire trade.

Personal.

J. S. Crider, Secretary of the Washington Carbon Company, Pittsburg, Pa., is in New York this week in the interest of his company. He reports a very large demand for their "Helios" cored carbons and also an increased trade in regular carbons, motor brushes and battery plates.

General News.

What is Going on in the Electrical World.

Savannah, Ga.—John R. Young has been appointed receiver of the Electric Railway.

Delaware, O.—The Electric Light Company, controlled by John H. Howison, B. L. Watkins and others, has assigned.

Staunton, Ill.—The city council at the February meeting will receive propositions for a franchise for an electric light plant.

Jackson, Tenn.—Prominent citizens here are urging the authorities to put in an electric light plant to be owned and run by the city.

Lima, O.—The storage barns of the Lima Electric Street Railway Company, together with ten cars, were destroyed by fire on the 12th inst.

Trenton, N. J.—C. F. Adam, manager of the Electrical Construction Company, has purchased the entire stock of the concern and will continue the business.

Boston.—The West End Railway's car house and thirty-five trolley cars were destroyed by fire on the night of the 15th inst. The loss is about $100,000.

Ottawa, Ill.—The city council has passed an ordinance granting the Thomas Electric Light and Power Company the right to establish a plant for lighting purposes.

New Castle, Pa.—The city councils have been investigating the subject of electric lighting with a view to the purchasing and operation of a plant under city ownership.

Norway, Me.—A preliminary survey has been made of the route of the projected Norway and South Paris electric railway; construction work will begin early in the spring.

Adrian, Mich.—Receiver Snow of the Adrian Electric Belt Railway Company has received permission from the Circuit Court to borrow $9,000 with which to re-equip the road.

Macon, Ga.—Tucker, Anthony & Co., of Boston, have purchased from the General Electric Company the Macon Consolidated Street Railway. Wm. A. Tucker will be the new treasurer of the road.

Richmond, Va.—There is every probability of the Broad street railway line being changed to an electric system. The company are willing to make the change as soon as they get the council's permission to do so.

Rome, Ga.—Eastern capitalists have recently purchased the larger part of the stock of the Electric Street Car Line and the Electric Light Company, and these concerns will hereafter be conducted under new management.

Flint, Mich.—The council has passed an ordinance granting a franchise to the Harrison Telephone Company to establish and maintain an exchange in this city, one of the conditions being that the company give the city free use of five telephones.

Orlando, Fla.—The Young Men's Business League have instructed their committee to examine into the matter of establishing an electric light plant, and if a favorable report is made will urge the council to pass an ordinance to that effect.

Tallahassee, Fla.—The council has granted permission to the Bell Telephone and Telegraph Company to establish a telephone exchange in this city. W. B. Rice has secured the requisite number of subscribers and forwarded the papers to the company.

Dallas, Tex.—C. L. Wakefield promises, in case this city gives him a franchise, to put in a thorough modern electric light plant, to cost from $40,000 to $60,000, the object being to furnish power and light in competition with the present company.

York, Me.—Hon. Edward S. Marshall intends to construct an electric light plant upon his land near the York Harbor and Beach Railroad station, and has petitioned the selectmen for permission to erect poles and string wires on the highway.

Herkimer, N. Y.—J. Ledlie Hess of Fonda and R. Townsend McKeever of Gloversville have acquired the three horse railroads which connect the villages of Herkimer, Mohawk, Ilion and Frankfort, in Herkimer county. The roads will be consolidated and operated by electricity.

Red Bank, N. J.—The Red Bank Electric Light Company's bondholders have agreed to surrender their securities for percentages of their face value to P. N. Jackson, who pays 90 per cent. for the first mortgage bonds, 50 per cent. for the second series, and 4¼ per cent. for the third series.

Newark, O.—Superintendent J. E. Young of the Newark electric light plant shows that the expense of operating the plant for the past six months was $640.38 less than that for lighting the city by gas. This takes into consideration $1,110.44 interest paid on $40,000 bonds for that period.

Helena, Mont.—The city clerk has been directed by a resolution of council to take such steps as shall be necessary to submit the question of bonding the city of Helena for the purpose of owning and operating its own system of water works and electric light to a vote of the taxpayers.

Bloomfield, Ind.—There is a movement on foot among the business men of Bloomfield, Worthington and Linton to put in an electric light plant at Switz City with force enough to supply the three towns. Switz City is a small town about six miles distant from each of the three towns named.

Hartford, Conn.—A bill has passed the House by a vive voce vote and been transmitted to the Senate, in which it is provided that no steam railroad in the State shall be crossed on grade by an electric, cable or horse railroad, nor shall any steam railroad cross any cable, electric or horse railway at grade.

Petersburg, Va.—Several of our prominent business men are in correspondence with an electric company of New York City with a view of securing cheaper telephone service for this city. It is understood the company is willing to establish a service here provided it is guaranteed 100 members and is granted a franchise.

Salt Lake City, Utah.—A contract has been entered into between the Salt Lake and Ogden Gas and Electric Light Company and the Big Cottonwood Power Company, by which the latter company undertakes to sell to the former all the electricity required for lighting, heating and power in the city of Salt Lake from Sept. 1, 1895.

Frederick, Md.—There is some prospect of the projected electric railway between Frederick and Middletown being built next spring, as interest in the scheme has been revived. The Middletown Valley people have raised nearly all of their share of the necessary fund. The road will be eight miles long and will cross the Catoctin Mountain.

Franklin, N. H.—The directors of the Franklin Falls Company have appointed a committee, consisting of E. H. Sturtevant, John W. Dresser and E. G. Leach, to secure plans and estimates for generating and distributing electric power on the ground and to any part of the town and for utilizing the water power to better advantage.

Jersey City, N. J.—At a meeting here last week of representatives of the traction companies of the State, a mutual protection society was organized with David Young, the general manager of the Consolidated Traction Company, as president, G. S. Browning, of Camden, vice-president, and William B. Price, of Elizabeth, secretary and treasurer.

Greensburg, Pa.—The Ligonier Valley Railroad Company intend to fit their road for electric cars as soon as arrangements can be made, and instead of two or three trains per day as now, electric cars will be run from Latrobe to Ligonier every hour or oftener if occasion requires. The heavy freight will be carried over the road by steam. The road is ten miles long.

Fall River, Mass.—The number of electrical appliances in use in the cotton mills in this city is increasing every day, and one electrical enthusiast is already looking forward to the time when long lines of shafting and belting will be replaced by long lines of copper wires that will lead from one central dynamo room to small dynamos near various sorts of machines.

Ennis, Tex.—The Texas Midland Railroad Company have equipped their Greenville and Ennis trains with electric incandescent lights, eighteen to each car, with projecting brackets from the side of the car, which makes it convenient for passengers to read. An engine and dynamo in the baggage-car furnish the power. This is said to be the first electrically lighted train in the South.

Birmingham, Ala.—A deal is on foot, and it is said has about been consummated, by which Birmingham will in the near future be provided with a new electric power station, electric dynamos and other apparatus necessary for generating electricity for an electric light system. Plans for a power station to cost approximately $200,000 have been submitted and estimates for constructing the same asked for.

Kutztown, Pa.—The Lehigh Valley Traction Company, which controls all the electric roads in Allentown, is making surveys through this section for the purpose of extending its lines through Emaus, Macungie and Trexlertown to this borough. From Kutztown the line is to be extended to Topton and thence is to follow the towns along the East Penn Railroad and meet the former electric line at Macungie.

Keokuk, Iowa.—J. C. Hubinger's schemes to build a high bridge across the Mississippi River, at this point, and also electric railroads to Nauvoo and other Illinois towns, have been killed by City Attorney Hollingsworth, who submitted an opinion to the city that there was no legal way for the city to enter into a contract to give Hubinger an electric-lighting contract for twenty years, which was the consideration he demanded for building the bridge.

Harrison, Ohio.—Ex-Representative James Graft, who recently incorporated the Harrison (O.) electric light plant, has under consideration a plan to light the villages of Cleves, New Haven and Miamitown. To this end a point centrally located will be selected, about four miles from Harrison, which will be the distributing point for the Harrison plant. Including the distance from Cleves to the distributing point the whole circuit would cover 16½ miles.

Chamberlain, S. D.—P. J. Gerin, of this city, has been appointed receiver of the Chamberlain Electric Light Company. The plant had been advertised for sale by virtue of a chattel mortgage, but other creditors of the company began proceedings, which resulted in Judge Haney issuing an injunction preventing the sale. There are several liens against the company, and the foreclosure of the mortgage would have shut out these claims.

Philadelphia.—The charges made by James Breen, a former employee of the Mutual Automatic Telephone Company, that a large amount of the stock of that company had been used to secure the passage through councils of the ordinance granting privileges to the company, has resulted in the appointment of a committee by common councils to investigate the matter.

South Orange, N. J.—The ordinance for the proposed trolley line through the township provides that the successful competitor for the franchise is to deposit $10,000 in cash with the township collector to be forfeited if the company fails to keep its agreement. The road is to be completed on July 1 and the company is to give $25,000 in bonds for living up to its agreement. The franchise is to be awarded to the company making the best bid for it.

St. Louis.—The *Republic* says: "Officials of the Edison Illuminating Company and the Missouri Electric Light and Power Company, and large stockholders of the Laclede Gaslight Company, which companies have all the contracts for city lighting, emphatically deny that there is any movement on foot at present to form a combine and thereby place the city in the hands of a powerful monopoly."

Sault Ste. Marie, Mich.—C. B. Robinson, manager of the Michigan Telephone and Telegraph Construction Company, is seeking a franchise for the establishment of an electric lighting system in this city. The new company will be composed of men of means from the southern part of the State and will start business with a capital of $1,000,000. It is the intention to make a reduction in current rates of 20 per cent. both for light and power purposes. The cost of lamps and fixtures will also be reduced.

Nevada, Mo.—The associated water, gas and electric light companies of Missouri and Kansas met in Nevada on the 14th inst. to organize in the interests of all companies in the two States. F. J. Tygard, president of the Butler Water Company, was elected president, and C. F. Strohm, receiver of the Nevada Water Company, secretary and treasurer. The date for the next meeting was not determined fully, but will be in February, and the meeting will be in Butler, Mo.

Chicago.—The *Times* says: "More than one-half of the jangling of telephone bells will be silenced in Chicago during the next six months. Within that time the Chicago Telephone Company will have placed in operation its new system of signals. A person using a telephone will be able to reach the one with whom he desires to talk, say what he wants to and end the conversation, all without the jangling of a bell. The signal to the operator in the exchange will be given by flash lights from an electric lamp."

Bangor, Me.—The Worcester Construction Company has been awarded the contract for building the Bangor Orono and Old Town electric railway. The completed road will be about fourteen miles long and will cost $250,000. The same company has also been awarded the contract for building the Beverly, Wenham and Gloucester electric railway. This road will be eighteen miles long, and will cost $250 000. The Construction Company will also supply all the cars and equipments.

Brooklyn, N. Y.—Bernard Gallagher has been elected president of the Citizens' Electric Illuminating Company vice H. M. McLaughlin. The change gives entire satisfaction to the stockholders.—The strike of the trolley railroad employees for fewer hours and a better system of payment still continues, causing almost a complete stoppage of the cars on the several lines. Some rioting has occurred, but nothing very serious has happened as yet. It is difficult to predict at this time how the affair will end.

Manchester, N. H.—The following special dispatch appeared in the *Union* under the heading "Enormous Dynamo": "Lancaster, Jan. 10.--Another dynamo is to be added to the electric light plant. It is to be of the latest improved specimen and will have a capacity of 14,000,000 volts per second. It has been constructed especially for volts, instead of the common kind of electricity." News of that kind in the *Electrical World* would not be astonishing, but in the Manchester *Union* it is simply phlogogenous.

Niagara Falls.—The first of the three great dynamos for the Cataract General Electric Company of Niagara Falls arrived there last week. Prior to its shipment this mammoth machine was thoroughly tested in the shops of the Westinghouse Company at Pittsburg, and was found to be capable of making 261 revolutions to the minute, eleven above the required number. Shafting and hydraulic connections for the dynamo are already in place and the prospects are now that the power will be ready for distribution by the 1st of February.

Gettysburg, Pa.—The Gettysburg Electric Railway has been sold to J. Luttrell Murphy, of Chicago, and Walter B. Kendall and John A. Connelly, of Philadelphia. The price paid is equivalent to $250,000. The purchasers obligate themselves to complete the road to the Maryland line, there to connect with the Maryland system of trolley roads. They are to obtain possession of the franchise on March 1, 1895, and in the meantime the present company will endeavor to settle the condemnation proceedings of the Government, which are now in process in the District Court of Philadelphia.

Buffalo, N. Y.—The subject of Niagara power continues to be one of the principal topics of conversation and discussion in this city. President Graves of the Citizens' Association has appointed as a committee to consider the manner in which electric power should be distributed in the city Messrs. J. N. Adam, Jewett M. Richmond, Henry W. Box, Richard Hammond, Ansley D. White, Walter J. Shepard and C. Lee Abell. Two corporations, the Niagara Falls Power Company and the Niagara Falls Hydraulic Power and Manufacturing Company, are now asking from the common council permission to use the public streets and roadways for the distribution of the electric current.

Detroit, Mich. Detroit capitalists are corresponding with Paw Paw citizens with a view to constructing an electric road to Lawton to connect with the Michigan Central. It is designed to use water power to run the generators.—The Wayne Circuit Court, all the judges concurring, has rendered a decision denying the application of the Detroit Citizens' Street Railway Company for a temporary injunction restraining the Detroit Railway Company, a new concern, from constructing and operating street railway lines in Detroit upon the ground that the complainant possessed the first right to all streets in the city for railway purposes under the terms of its franchise.

Pittsburg, Pa.—The *Post* says: "Another gigantic street railway has been projected, and a company of Pittsburg capitalists has been organized to extend the electric street railway line from Washington, Pa., through the numerous towns on the Chartiers branch of the Panhandle Railroad into Pittsburg. An application has been made for a charter and work on the line will be begun as early in the spring as the weather will permit. The new company is composed of President Francis J. Torrance, treasurer and general manager of the Standard Manufacturing Company; Thomas B. Hutchinson, a prominent local structural iron and steel manufacturer; A. E. Townsend, president of the Washington Railway, and Senator Arthur Kennedy, a director in the Allegheny Valley Railroad and the Bellevue Land Company."

Albany, N. Y.—A bill has been introduced in the Senate by Senator Owens providing that in New York and Brooklyn the price of electric lights shall not exceed one half cent per light per hour for incandescent lights, nor more than four cents per hour per light for each arc light. Other bills introduced: In the Senate—Providing that contracts for electric lighting in Brooklyn may be made with the consent of the Mayor for not exceeding five years; in the House—Providing that telegraph companies shall charge only one cent a word for the body of day messages, for all distances, and one half cent a word for night messages for all distances; providing that in cities of over 250,000 inhabitants, electric cars shall not be run at a speed greater than six miles an hour. Senator Raines's bill giving electric light companies right to acquire right of way was reported in the Senate.

New York.—The Edison Electric Illuminating Company held their annual meeting in this city on the 15th inst. The year's report showed station earnings of $1.369.066 and operating expenses of $550,426. Other sources of income, less legal expenses and taxes, $124,443, leaving the net earnings at $789,466. The company also received royalties on the Edison lamp of $46,000; $207.266 interest on bonds, and $476,196 in dividends were paid, leaving $152,004 to be carried to the surplus.—The Board of Electrical Control reorganized on the 17th by electing Mayor Strong as chairman and Henry S. Kearney as secretary.—In the bicycle exhibition now being held in Madison Square Garden, there is an electric sign extending across the entire east end of the garden, 108 feet in length by 35 feet in width, which contains 2,192 lamps aggregating 29,147 candle power. The electrical illumination is the finest ever seen in the garden, and lends a brilliant effect to the magnificent aggregation of bicycles.

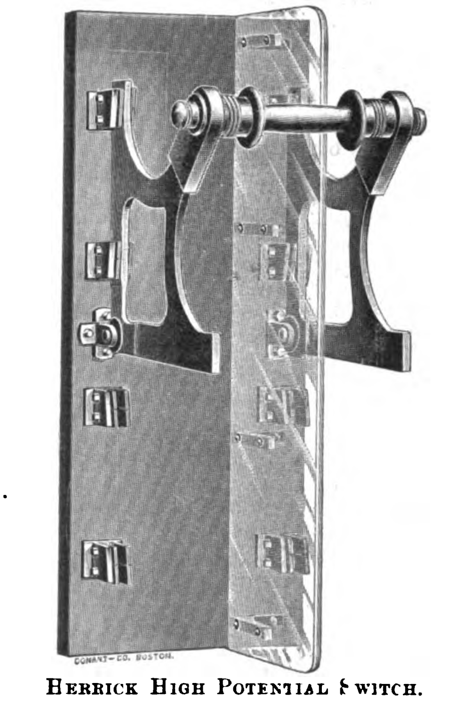
A New High Potential Switch.

We illustrate a new type of High Potential Knife Switch, designed by Charles H. Herrick, E. E., 183 Oliver street, Boston, Mass., and manufactured by the well-known firm of W. S. Hill Electric Company, 183 Oliver street, Boston, Mass.

The engraving shows one of a group of six switches now in use at the Narragansett Electric Lighting Co.'s station, Providence, R. I., where they are successfully carrying currents of 400 amperes at 1,000 volts, alternating current.

With the advent of large direct connected generators a need for a switch to handle and transfer the heavy currents was felt, and Mr. Herrick has successfully met the demand. It will be seen that the switch is very quick break, has a flash guard between its opposite poles, breaks both machines and circuit, and has its yoke at a point of absolute safety both to operator and switch. In operation there is no flash when switch is thrown and the slightest possible "wink" in the lamp to which it supplies current.

It will also be seen that our illustration shows a switch adapted for use on the front of switchboards, but designs have been completed for the same type of switch to be placed on the rear of the board. This type is operated by a lever and handle extending through a slot cut in the switchboard. The switch has solid cast copper blades, micanite insulation on yoke and the well-known Hill reinforced contacts, and will be given a carrying capacity of 50 per cent. in excess of its regular duty to allow for all reasonable overloads. It is adapted for all varieties of duty from 110 and 500 volt circuits to those carrying 2,000 volts and over, alternating current.



CONANT—CO. BOSTON.

HERRICK HIGH POTENTIAL SWITCH.

It is the intention of the Hill Company to build these switches in all sizes and types as demand may arise for them, and will design this switch to perform any special duty and guarantee results. The Hill Company have given it the name of "Herrick High Potential Switch."

As stated above, our illustration shows the switch in use on the alternating switchboard designed by Mr. Herrick for the Narragansett Electric Lighting Co., which is capable of handling 50,000 to 100,000 16-C. P. lamps. The design of this board is such that all changes of machines and circuits are made instantly and without the use of plugs or cables of any sort. The generators can be arranged to run in multiple or independently as desired, provision being made in the design of the board to admit of this feature. This board was also the product of the Hill Company's shops and is strikingly handsome, being 22 feet by 6 feet in size and the material Italian marble.

The Hill Company will be glad to answer all inquiries, make quotations, etc., to all who may be interested.

Wallace & Sons.

We beg to notify our friends that our new Catalogue for 1895 will soon be ready.

This Catalogue will contain the Latest Revised Price-Lists of goods of our manufacture that are in force at this writing. Yours truly,

WALLACE & SONS.

New York, January, 1895.

The Joseph Dixon Company.

"Graphite as a Lubricant" is the title of an interesting pamphlet issued by the Joseph Dixon Crucible Company of Jersey City. The pamphlet is now in the third edition and will be sent on application.

INCORPORATIONS.

The American Electric Meter Company, Camden, N. J.—to manufacture, buy, sell and erect electric meters, electrical machinery, appliances, etc. Capital stock, $100,000. Promoters: Wm. D. Marks, Walter F. Smith, James F. Cray, all of Philadelphia, Pa.

The Phœnix Telephone and Electric Company, Denver, Col.—to sell, lease and deal in telephones, telephone lines, systems and electric and magnetic appliances, instruments, etc. Capital stock, $750,000. Promoters: Gurnsey Walker, Preston H. Barker, Alfred W. Chamberlin, Denver.

The Milwaukee Dynamo Company, Milwaukee, Wis.—to do a general electrical business and sell electric goods. Capital stock, $15,000. Promoters: W. A. Ehlman, Jno. Koerta, Theo. Egelhoff, Milwaukee.

The Franklin Telephone and Electric Company, Jersey City, N. J.—to manufacture, buy, sell, build and use electrical machinery, etc. Capital stock, $200,000. Promoters: A. O. L. Havens, Point Pleasant, N. J.; John McG. Goodale, John R. MacArthur, New York City.

The St. Louis County Electric Light and Power Company, Clayton, Mo.—to furnish light and power for public and private use. Capital stock, $5,000. Directors: M. B. Greensfelder, E. W. Warfield, E. H. Benoist, E. L. Dosenbach, Charles Cunningham, Dr. Young, H. Bond and C. K. Ramsey. One of the leading objects of the enterprise is to furnish power for several electric railways that are shortly to be built in the county.

The St. Louis County Telephone Company, Clayton, Mo. Capital stock, $5,000. Incorporators: M. B. Greensfelder, E. W. Warfield, O. H. Benoist and others.

The West Shore Electric Light Company has filed articles of incorporation at Hackensack, N. J. Capital stock, $100,000. Incorporators: John A. Dempsey, Guy C. Dempsey, New York; Leon Abbett, Jr., Hoboken, and Robert W. S. Negus, Bogota. The places of business will be Ridgefield, Englewood, Palisades, Harrington and New Barbadoes. This includes all the property proposed to be covered by the Bergen Traction Company, of which the electric light company is supposed to be a branch.

The New York Electric Exchange Company has filed papers of organization with the county clerk at Newark, N. J. Capital stock, $100,000. Incorporators: James E. Blackmore, Bartlett Blackmore and Daniel M. Mandrell, all of Newark.

The Electric Purifier Company, Chicago. Capital stock, $800,000. Incorporators: George H. Reynolds, A. B. Jenkins, W. T. Rankin, W. M. Culley, Henry S. Williams.

The Newman Canning and Electric Light Company, Newman, Ill.—to can vegetables and operate an electric light plant. Capital stock. $14.000. Incorporators: B. Thomas, Joseph Venders, L. W. Root, W. J. G. Pound and J. H. Scotten.

The Staten Island Terminal Electric Company—to build and operate a street surface railway from the ferry landing at St. George to New Brighton. Capital stock, $50,000. Directors; Herman Bergholtz, De F. VanVleet, Franklin C. Cornell, Daniel Thomson, C. J. Rumsey, of Ithaca; Frederick Leuchter, Port Richmond, S. I.; Alfred Hendricks, New York City; Grant Crabtree, New Brighton, S. I., and W. H. Bostwick.

The Spiral Wire Company, Portland, Me.—to carry on the business of electric lighting, power, etc. Capital stock, $1,000,000, of which $215 is paid in. Incorporators: W. G. Burnham, J. W. Briggs and Gorham Gray, all of Boston.

The Napoleon, Deshler and Northwestern Railroad Company has been incorporated at Columbus. The object is to build an electric road from Deshler, Henry County, to Montpelier, Williams County, Ohio. Capital stock, $50.000. Incorporators: M. Donnelly, Robert K. Scott, W. O. Hudson, J. W. Hanna, D. Merkison, George Eggers, D. W. Humphrey and W. P. Tyler.

The Great Northern Electrical Manufacturing Company, St. Paul, Minn.—to manufacture and sell automatic electric annunciators, electric fire, police and burglar alarms, etc. Capital stock, $100,000. Promoters: Henry F. Hoyt, Jno. F. Hoyt, St. Paul; Rob't L. Hunter, Minneapolis.

The Nantucket Electric Company, Nantucket, Mass.—to generate and sell electricity for light, heat and power, etc. Capital stock, $20,000. Promoters: Fred. Howard Porter, John R. Bacon, W. A. Clark, Jr., Geo. L. Smith, Henry A. Burnham.

The Nutting Electric Company, Chicago, Ill.—to manufacture, buy, sell and deal in merchandise and do a general contracting business. Capital stock, $50,000. Promoters: Carl K. MacFadden, Frank A. Smith, Jas. W. Hedenberg.

The Combination Power Company of Chicago, Chicago, Ill.—to acquire patents protecting power-supplying devices; to lease on royalty or sell the right to use the same on railway engines, power plants, vessels, and manufacture power. Capital stock, $500,000. Promoters: Jno. E. Anderson, Isaac T. Dyer, L. I. Blades.

The Denver Heat and Light Company, Denver, Col.—to operate and maintain electric generating stations, machinery and wires for transmitting electricity for furnishing light, heat and power, etc. Capital stock, $1,000,000. Promoters: John C. Feldwisch, F. Cobb, Thos. Mohr, of Denver.

The Anglo-American Electrical Association, Brooklyn, N. Y.—to manufacture and sell magnetic clothing and all medical, surgical and curative preparations and appliances into which electricity enters as a factor or agent. Capital stock, $100,000. Directors: Frederick A. Blake, Emma L. Blake and Alice R. Lucas.

RECENT COMPANY ELECTIONS.

Dolgeville Electric Light and Power Company, Dolgeville, N. Y.—President, Edmund R. Wanekel, of New York; secretary, N. A. Snell; treasurer, W. S. Armstrong. Executive committee: Alfred Dolge, W. S. Armstrong, C. W. Millett. Directors: Alfred Dolge, Wyman Eaton, E. R. Wanekel, N. A. Snell, Wheeler Knapp, G. A. Freygang, Charles Dedicke, Edward A. Brown, C. W. Millett, Calvin Brockett, W. S. Armstrong, Louis Cavalli and Karl Fink, of New York.

New Orleans Traction Company, New Orleans, La.—President, James H. Maury; vice-president, R. M. Walmsley; general manager, H. M. Littell. Directors: James H. Maury, Albert Baldwin, R. M. Walmsley, Henry Bier, Frank T. Howard, C. H. Hyams and J. C. Denis.

East Reading Electric Railway Company, East Reading, Pa.—President, A. J. Brumbach; vice-president, J. G. Leinbach; secretary, A. Fedgely; treasurer, Isaac W. Levan. Directors: A. J. Brumbach, William R. McIlvain, J. Augustus Strohecken, Jonathan G. Leinbach, John H. Printz, George W. Bard and Frank P. Esterly.

Norristown Power Company, Norristown, Pa.—President, Joseph Shaw; vice-president, I. H. Brendlinger; treasurer, Wm F. Solly; secretary, B. F. Keiper. Directors: Joseph Shaw, I. H. Brendliger, Wm. F. Solly, Geo. W. Smith, James McGlinnis, Isaac W. Smith, John Slingluff, S. S. Kohn, Solomon Gilbert, J. Evans Isett and H. C. Crawford.

Pen Argyle, Bangor and Water Gap Electric Railway Company was lately reorganized at Easton, Pa., and the following officers elected: President, J. C. Merrill; secretary and treasurer, C. Albert Sandt. Directors: C. Albert Sandt and John Bitters, of Easton; Erwin Merrell, C. C. Wise and W. F. Jordan, of Bangor, and E. V. N. Hurmance, of New York City. President Merrell says he has such assurance of financial aid as to lead him to believe that the road will be speedily built.

H. B. Morehead has been elected general manager of the Cincinnati, Hamilton, Middletown and Dayton Electric Railroad Company.

Westinghouse Electric Light, Heat and Power Company, York City, Pa.—Directors: Logan A. Marshall, Edward Stubk, Geo. F. Motter, J. A. Walker, George B. Rudy, Charles Baylor, H. A. Wasbers.

Toledo and Maumee Valley Electric Railroad Company—Directors: Parks Foster, A. K. Detwiler, G. G. Metzger, W. B. Taylor and Thomas B. Tracy.

Sandusky Electric Street Railway Company, Sandusky, Ohio—Directors: A. J. Stoll, J. S. Cowdery, C. H. Moss, James Flynn, C. G. Nielsen, J. H. Emrich, Homer Goodwin.

Brush Electric Light and Power Company, Savannah, Ga.—President, S. P. Hamill; vice-president, D R. Thomas; secretary, W. K. Wilkinson. Directors: John C. Rowland, D. Y. Dancy, J. R. Sheldon, A. Minis, L. Kayton, W. W. Mackall, J. S. Collins, George W. Allen, J. Rauers.

Reading Traction Company, Reading, Pa.—Directors: John A. Rigg, Robert N. Carson, R. Nelson Buckley, Richmond L. Jones and David C. Golden.

Edison Electric Illuminating Company, New York—Directors: A. H. Boissevain, R. R. Bowker, C. H. Coster, C. E. Crowell, Thomas A. Edison, W. E. Glyn, D. O. Mills, George F. Peabody, W. A. Read, F. S. Smithers and Spencer Trask.

Adrian Electric Belt Street Railway Company, Adrian, Mich.—President, S. E. Graves; vice-president, W. A. Jackson; secretary, Charles F. Barker; treasurer, M. E. Chittenden. Directors: W. A. Jackson, F. E. Snow, Clark Rude, J. H. Blain, S. E. Graves, C. F. Barker and M. E. Chittenden.

Northampton Electric Lighting Company, Northampton, Mass. President, Alexander McCallum. Directors: A. McCallum, C. H. Pierce, C. E. Gould, S. B. Fuller, John T. Stoddard.

Boulder Electric Light Company, Boulder, Col.—Directors: Dr. I. L. Bond, J. H. Nicholson, Geo. M. McClure, Dr. R. Bartlett and B. M. Williams. The first three were elected president, secretary and treasurer respectively.

Rochester Electric Railway Company, Rochester, N. Y.—Directors: H. Sellers McKee, Pittsburg; Benjamin Graham, New York City; Herace Magee, Philadelphia; T. De Witt Cuyler, Philadelphia; John N. Beckley, Hon. Frederick Cook, Marcenus H. Briggs, Arthur Luetchford, William C. Barry, Chauncey C. Woodworth, Hon. Charles S. Baker, Charles F. Pond and Patrick Cox, of Rochester.

At the annual meeting at Norristown, Pa., of five electric railway companies in which the Me Shepp have a controlling interest, the five compa were merged into one, each retaining its own officers. following officers were elected: Citizens' Company President, D. B. Shepp. Directors: J. W. Shepp, D. Shepp, W. B. Krick, Joseph Fornance. Ambler Compan —D. B. Shepp. Directors: J. W. Shepp, D. B. Shep Henry Parker, E. Murphy, W. B. Krick. The officers of th Conshohocken, the Montgomery County and the Norristown Companies are the same as those of the Ambler Company.

At a meeting of the board of directors of the Susquehanna River Electric Company, which, as before reported, was organized to bring electric power from Conowingo to Baltimore after the Niagara Falls plan, J. W. Marsh, of Pittsburg, was elected president of the company, M. H. Houseman retiring from that position and becoming vice-president. John S. Bull having resigned as a member of the board of directors, was appointed real estate agent of the company. Winfield J. Taylor was appointed counsel of the corporation.

Woven Wire Brushes.

The Belknap Motor Company of Portland, Me., are the patentees and manufacturers of the best Woven Wire Brush on the market.—[*Adv.*

LETTERS PATENT ISSUED JANUARY 15, 1895.

ELECTRIC RAILROADS AND APPLIANCES.

532,448. Conduit Railway Trolley. William T. Dulany, Jr., New York, assignor of one-half to Oscar F. Shaw, Brooklyn, N. Y. Filed March 30, 1894.

532,449. Conduit Electric Railway. William T. Dulany, Jr., New York, assignor of one-half to Oscar F. Shaw, Brooklyn, N. Y. Filed Aug. 16, 1894.

532,477. Trolley-Catcher. Martin V. B. Nichols and James A. Fraser, Port Arthur, Canada. Filed May 26, 1894.

532,538. Controller for Electric Cars. Harry P. Davis, Pittsburg, Pa., assignor to the Westinghouse Electric and Manufacturing Company, same place. Filed April 14, 1894.

532,576. Closed-Conduit Electric Railway. George W. McClintock, Wollaston, and Daniel J. McLane, Quincy, Mass. Filed July 2, 1894.

532,599. Closed-Conduit Electric Railway. John Schnepf, New York, N. Y., assignor of one half to William H. Bellamy and William C. Doscher, same place. Filed Sept. 9, 1893.

532,593. Converter System for Electric Railways. Charles F. Scott, Pittsburg, Pa., assignor to the Westinghouse Electri and Manufacturing Company, same place. Filed July 31, 1893.

ELECTRIC LIGHTS AND APPLIANCES.

532,468. Carbon Filament and Method of Manufacturing Same. Arthur D. Little, Boston, Mass., assignor to the American Viscose Company, same place. Filed June 18, 1894.

532,531. Electric-Arc Lamp. Arthur Chester and John J. Rathbone, London, England. Filed March 26, 1894.

DYNAMOS, MOTORS, ETC.

532,441. System of Power Transmission. Charles S. Bradley, Avon, N. Y. Filed Sept. 12, 1893.

532,475. Brake for Electric Motors. William H. Morgan, Alliance, Ohio, assignor of three-fourths to Thomas R. Morgan, Sr., Thomas R. Morgan, Jr., and John R. Morgan same place. Filed March 19, 1894.

532,514. Electric Elevator and Motor Controller. Robert Wilson, Louisville, Ky., assignor to the Sulzergvogt Machine Company, same place. Filed June 23, 1894.

532,537. Automatic Circuit-Breaker. Harry P. Davis, Pittsburg, Pa., assignor to the Westinghouse Electric and Manufacturing Company, same place. Filed Feb. 28, 1894.

532,549. Alternating-Current Motor. Ludwig Gutman, Pittsburg, Pa. Filed Aug. 27, 1890.

TELEPHONE AND TELEGRAPH APPARATUS.

532,605. Annunciator for Telephonic Circuits. Theodore Spencer, Cambridge, assignor to the American Bell Telephone Company, Boston, Mass. Filed Sept. 10, 1894.

BATTERIES.

532,701. Mechanism for Forming Battery-Plates. Charles J. Reed, Philadelphia, Pa., assignor to the Reed Electric Company, same place. Filed Sept. 12, 1894.

MEASURING INSTRUMENTS.

532,559. Galvanometer. Adrian H. Hoyt, Penacook, N.H., assignor to the Whitney Electrical Instrument Company, Saco, Me., and Manchester, N. H. Filed April 25, 1894.

532,560. Galvanometer. Adrian H. Hoyt, Penacook, N.H., assignor to the Whitney Electrical Instrument Company, Saco, Me., and Manchester, N. H. Filed April 25, 1894.

532,561. Galvanometer. Adrian H. Hoyt, Penacook, N.H., assignor to the Whitney Electrical Instrument Company, Saco, Me., and Manchester, N. H. Filed April 25, 1894.

MISCELLANEOUS.

532,588. Contact Device for Electrical Appliances. Friedrich W. Schindler-Jenney, Kennelbach, Austria-Hungary. Filed Feb. 19, 1894.

532,594. Non-Arcing Switch. Charles F. Scott and Harry P. Davis, Pittsburg, Pa., assignors to the Westinghouse Electric and Manufacturing Company, same place. Filed March 29, 1894.

532,633. Railway Block-Signal. William Berrigan and William H. McClure, Elmira, N. Y. Filed Sept. 18, 1894.

532,662. Electric Switch. William P. Hancock, Everett, Mass. Filed Nov. 27, 1894.

532,718. Phonograph. Joseph Broich, Brooklyn, assignor to Frederick Pearce, New York, N. Y. Filed Dec. 13, 1893.

532,712. Magnetic Separator. Henry Arden, Seattle, Wash. Filed Aug. 15, 1894.

"HELIOS" CORED CARBONS

FOR ALTERNATING AND DIRECT CURRENTS.

Attempts have been made in this country to produce a satisfactory "Cored" Carbon, but failure resulted in every case. We can now assure the Electric Light Companies that our "HELIOS" CARBON is made of the same ingredients, in precisely the same way,

BY THE MAN WHO MADE THEM IN GERMANY.

We shall be glad to hear from the Electric Light interests in relation to carbons for both Alternating and Direct Currents.

A memorandum book with tables showing the relation between millimeters and inches, with a list of ordinary sizes of "HELIOS" Carbons of our manufacture, will be sent on application.

Siemens & Halske Electric Company of America

Siemens & Halske: Berlin, Charlottenburg, Vienna, St. Petersburg.

MANUFACTURERS OF

Direct Current Slow Speed Multipolar Generators and Motors.

These machines are constructed with *external armatures*. They have proved remarkably efficient and economical. Used largely in American and European Lighting and Railway Plants. Slow-speed machines, made for direct connection in sizes from 20 H. P. to 2,000 H. P.

ADVANTAGES OF OUR EXTERNAL ARMATURE TYPE:

Maximum peripheral speed of armature with slowest engine speed. Shortest possible winding of armature. Lowest internal resistance of armature.
Only 3 to 4 volts difference of potential between commutator bars. Greatest radiating surface possible. Maximum magnetic effect.
Greatest weight of copper per ampere of current. Armatures cannot burn out. Great compactness.
Correct mechanical design. (The centrifugal force is counteracted effectively by the inward pull of the internal field magnets.)
Finest quality of iron, excellent finish, absence of binding wire.

In 8 years' continuous service not one Armature has been replaced or repaired. **Over 200,000 H. P. in use for Railway, Lighting and Motor Service.**

WORLD'S FAIR DIPLOMA AND MEDAL FOR BEST DIRECT CONNECTED GENERATOR.

MODERATE SPEED BIPOLAR GENERATORS AND MOTORS,

With Siemens Drum Armatures, which are copied extensively in this country. We are building these machines in sizes from 1 H. P. to 150 H. P.

if you will dig

into the question of insulated line wires you can unearth some curious facts.

1ST FACT is that "skimmed milk ofttimes masks as cream," in other words, what seems to be insulation is nothing of the kind—simply a cloak under which to sell bare copper at a liberal profit.

2D FACT. The first cost of real live insulation cuts very little figure. Go behind all of that and see what you actually get for the money. If the insulation is *stable, lasting, honest*, your investment will repay itself times over.

3D FACT. An honest insulation will bear a great deal of watching. You can dig into **CANDEE WEATHERPROOF** all you like, you won't unearth a skeleton; you will find considerable meat on the bone.

IT WON'T FRY OUT.

THE "CLARK" WIRE.

In a Letter from the Inspector of the Boston Fire Underwriters' Union, he states: "A Thoroughly Reliable and Desirable Wire in Every Respect."

For Switchboard, Railway and Motor use, we make all sizes of Stranded and Flexible Wire and Cables with Clark's Insulation.

The Clark Wire has been before the public and in use for the past nine years, and has met with universal favor. Thousands of miles of this wire have been sold, and are in use throughout the United States and Foreign Countries, and the demand for it is constantly increasing because it always gives perfect satisfaction.

than any alternating machine on the market.

SELF-STARTING TWO PHASE MOTORS,

superior in many ways to direct current motors.

THE BEST TRANSFORMER.

These are the essential elements in our

TWO PHASE SYSTEM,

which is the only practically completed system in operation to-day for furnishing light and power from the SAME ALTERNATING GENERATOR AND CIRCUIT.

STANLEY ELECTRIC MFG. CO., PITTSFIELD, MASS.

Western Office, No. 307 Dearborn Street, Chicago, Ill.

WHY DO YOU ADVERTISE?

Do you pay out several thousand dollars every year "merely to be represented" along with your competitors, or do you expect it to bring you business?

WHO ARE YOUR CUSTOMERS?

Are they college professors and theoretical electricians, or are they the Central Station managers, the street railway men, and the artisan?

HOW MANY

Artisans, capitalists or business men can understand a purely technical paper, however valuable it may be to its scientific constituency? How many Central Station men have the time or the taste to wade through intricate formulae, or to trace the thread of mathematical logic?

ARE NOT

These questions worthy of your consideration? Can you afford to continue firing into the air?

TO SECURE RETURNS

Place your advertisements in papers read by the men who buy the goods. ELECTRICITY is the only Electrical Journal which professes to handle the subjects of which it treats so as to bring them within the scope of all; it is *the only popular electrical weekly in this country*—popular, practical, yet technically correct,

ELECTRICITY NEWSPAPER CO. 6 PARK PLACE, N. Y.

THE WELSBACH LIGHT,

CRITICISMS SHOWING ITS FAULTS AS AN ILLUMINANT.

N. E. L. A.—The next annual meeting of the National Electric Light Association will be held at Cleveland, O., February 19-21, 1895. Every concern interested in either lighting or railway work should be represented in the membership of this body, and should have at least one representative at the Cleveland meeting. The Secretary is Mr. Geo. F. Porter, 136 Liberty street, New York.

EDITORIAL NOTES.

An Important Decision. Judge Gaynor's decision in the mandamus proceedings against the Brooklyn Heights Railroad Company, when carefully studied, must command the respect of even the most partisan advocates of the corporations themselves.

He brushes aside all other questions, and presents the duty of the companies to the public. That duty is to run cars. The question of proper wages has nothing to do with the case, neither has the lawlessness of the strikers. If property is destroyed through want of protection, the companies have redress against the city in a lawful and regular proceeding.

It is not contended by the companies that they *can not* run cars, but that they would lose money by meeting the demands of their striking employees. Judge Gaynor holds that it is not for the courts to see that these companies do not lose money. The city does not guarantee profits in granting charters. The charter is a contract in which the companies agree to give proper service to the public. This service they must perform.

The suggestion that they may hire men at lower wages, one by one and as fast as possible, providing a new force if need be by degrees and *without stopping their service*, is not only good law, but it is common sense. It is a policy which would go a long way towards abolishing strikes.

It need not be pointed out that the relations of railroad corporations to the public are entirely different from those of the private employer of labor. The latter may close his works indefinitely. The former should not be allowed to discontinue their service for one hour from reasons of economy.

On the other hand, we must consider the position of the striker. Even if he be partly in the wrong in the beginning, he usually starts out with the sympathy of the public. But as a complainant he must come into court with clean hands. He cannot invoke the law's protection against a practice of which he himself is proven guilty. It is the unfortunate outcome of all strikes that sooner or later, no matter how just his cause at first, the striker commits offences against the law that put him beyond the pale of its protection. Doubtless much of the lawlessness attending strikes is committed by outside parties, but it is not always the case, and it has been proven in many cases, as in the Brooklyn trolley strikes, that some of the strikers themselves have been guilty of some of the most flagrant of the offences. It may be stated as a law that public opinion will eventually turn against the infractors of the law, and without the sympathy of the public no cause can be successful. The American public is proverbially good-natured and long-suffering, but when it learns from repeated experience that strikes are invariably accompanied by riotous proceedings and other infractions of the law, it must turn against the institution, and the side which is least conspicuous in its public infractions will have the most sympathy. Mayor Schieren is certainly right in the stand he has taken, that the period of riots is not the time for arbitration. That should take place before mob law takes sway. If unfortunately it cannot be arranged for at that time, then the opportunity is gone until the disturbances have ceased. Arbitration with the revolver is not arbitration and can never result in ultimate good to either side.

As we go to press, a very clever scheme is announced on the part of the strikers, the outcome of which will be awaited with interest. In order to disarm the Brooklyn Heights Company, should they be called to answer a charge of contempt in not obeying Judge Gaynor's order, Master Workman Connelly has addressed a letter to President Lewis, offering the services of all the men he needs upon the terms in force during 1894. In addition to this, it is reported that a large number of individual motormen have sent letters, offering to go to work again upon the terms suggested by Connelly.

It is claimed that according to Judge Gaynor's order there are only two sufficient excuses for not running cars on regular time. Mob violence is one, and the inability to engage men another. Judge Gaynor claims that the company has sufficient protection against the first, which however is likely to be disputed, whereas if President Lewis claims he cannot get men, copies of these letters will be put in evidence against him, and the enforcement of the mandamus be demanded by the Knights of Labor. The unfortunate thing for the Knights, however, is that there has been, and still is, at present writing, mob violence. Until this ceases absolutely the strikers' case has no ground to stand on.

* * *

New Scientific Periodicals. It is something unusual for us to be called upon to give space the same week to the review of two new claimants for public favor in the line of periodical literature, but it so happens that this is the case now, for in this issue we discuss two new periodicals at considerable length. The claims which these two periodicals have for our attention are based, however, upon entirely different premises. While the one deserves comment because it is so good, the other deserves equal attention because it is so utterly bad. That the two reviews are brought so strongly into contrast is purely the result of fortuitous or other chance, and not of design. In the case of the *New Science Review*, we have nothing of a commendatory nature to say. The best that can be said is that it had a splendid opportunity, but has recklessly thrown it to the dogs. With a splendid appearance, fine make-up, clear typography and a broad field almost unoccupied before it—starting out with a few names that would challenge respect and attention wherever those names were heard, it has deliberately forfeited that respect, brought odium upon its attractive title and belied the promises of its prospectus by giving place to a class of articles that should find no place in literature of any kind, much less that going under the head of Science. We had heard it rumored that the magazine in question was to be the organ of the Keely-motorites as represented by their at present most prominent mouthpiece, Mrs. Bloomfield Moore. We were loath to believe this at first, but the appearance of the third number lends strong confirmation to the report. We have no criticism to make of Mrs. Moore as an individual, but as a philosopher, to use a homely expression, she is as clear as mud. A good second to her is Henry Clay, or his materialized spirit, who discourses glibly in the same number of such things as "oppositions being proportionally equilibrated," and "the average harmony" and "sympathetic portion of the vibration, that with which it (the light rays) may be in harmony," etc., etc. It is hardly conceivable that any sane editor could accept such trash as having any meaning, and the only recourse left us is to assume as true the rumor that this is to be the repository of all such nonsensical twaddle as writers of this stamp, faith-curists, spiritual mediums and that ilk delight to indulge in. We fancy that the reputable contributors whose names have unfortunately been connected with the journal will regret their connection with it, and withdraw entirely, so that the twaddlers may have full sway and unrestricted room in the issues that are to come, if indeed the publication can survive another issue.

Of quite a different class is the second publication, which in name is old, but in form and nearly everything else is new. We refer to *Electric Power* in its magazine form.

Under the Searchlight.

Views and Opinions on Timely Topics.

The Bate Refrigerator Case.

The Bate Refrigerator case, which was argued before the U. S. Supreme Court November 15, 16 and 17, 1894, and upon which a decision has been expected every Monday since the Court reconvened, has not yet been decided. The next recess will begin February 4 and will last for a month. This recess is taken for the purpose of giving the Judges time to write their opinions, and it seems probable now that nothing further will be heard of the case until after the February recess. The slump in General Electric on Monday, which brought the stock down to 29⅜—the lowest figure yet reached—was therefore due in no way to a decision as many supposed.

* * *

The Roll of Honor.

A recent pamphlet issued by Mr. W. J. Johnston, the man who not only wants to run his own business but everybody else's, gives a list of concerns who advertise "only" in the *Electrical World*, and also a list of those who advertise in other papers. The first list, as is customary with both the printed and spoken remarks of the gentleman named, is a lie, containing as it does a large number of regular patrons of other journals.

Apart from the inaccuracies, the list is a good one for advertisers to study.

It shows that every concern of consequence patronizing the *World* exclusively has a competitor, doing twice or even ten times the business, advertising in other papers, included in list No. 2.

The moral to this is as old as the business of advertising: The wise man scatters his advertising and increases his business.

* * *

Organized to Abet Crime.

Some weeks ago when ELECTRICITY had thoroughly exposed the electro-medical fraud Electropoise, and called the attention of the leading religious journals and the monthlies to the fact that they were assisting in the promulgation of a fraud upon their readers, the advertising agents of these various publications held a meeting to discuss the situation.

It was finally decided that they would continue to publish the advertisements of the Electropoise as long as they could get paid for it, regardless of the merits or demerits of the article. They held that it was not their business to decide as to the quality of the article advertised, and that ELECTRICITY's publication could not injure them much, the paper being in a different field.

This is about the tone of morality and decency which might be expected to find expression at a meeting of Tammany politicians, but scarcely what we have a right to look for from the leading religious organs of America.

At slight expenditure any of these journals could make an examination similar to the one ELECTRICITY made, but this would stop their income from a criminal business, and this they have no intention of doing. The source of the income is of small moment; even if they sell their souls to get them, they must have advertisements. Thus they grow rich and pose as pillars of the church which they disgrace.

The *Churchman*, the *Observer*, and the other religious journals which have persisted in printing the advertisement of the Electropoise since ELECTRICITY's analysis, and also the *Review of Reviews*, the *Literary Digest*, and other secular journals, have shown conclusively that they would print lottery or green goods advertisements, Scotch Oats Essence testimonials, or anything else in the shape of fraudulent advertisements, IF THEY DARED.

Conscience does not guide them; they come just as near the line of being excluded from the mails as they dare.

They want money and evidently hold that the money of the swindler is as good as any other.

* * *

G. E. Directors Will Take Notice.

The indictment of Messrs. Henry B. Beecher and Vincent R. Schenck, charged with issuing a false report of the affairs of the American Casualty Company in 1891, is a wholesome sign.

It is of course not fair to assume that these men are guilty of the crime charged. If innocent they will be vindicated. But the incident shows that there are stockholders in, and creditors of, some companies with backbone and courage enough to try and secure the punishment of those believed to be responsible for public misrepresentations.

Section 611 of the Penal Code provides that "a director, officer, agent or employè of any corporation or joint stock association who knowingly concurs in making or publishing any written report, exhibit or statement of its affairs or pecuniary condition containing any material statement which is false is guilty of a misdemeanor."

Did the G. E. directors have this in mind when they resolved that casual statements don't go, and that all recent statements (favorable and unfavorable) regarding the company's affairs were false?

But how about the first annual report? Is that to go into history as a "casual statement?"

* * *

New York is the Place.

The suggestion made in ELECTRICITY two weeks ago, that New York should be the next meeting place of the N. E. L. A., has met with nothing but favorable comment from all quarters. Those who have visited the Grand Central Palace are enthusiastic in their opinion that no other building in the country presents so many advantages for the Convention proper, for the exhibitors, and for a memorable social event.

* * *

All There Is in the Classics.

Read Homer's Iliad, Virgil's Æneid, and then read the *Western Electrician's* phillipic on Pudd'nhead Johnston in the issue for January 13, and you have all there is of essential importance in the classics.

* * *

THE commercial instinct displayed by a couple of Cleveland gentlemen in mixing up the local entertainment committee with the sale of space to exhibitors is worthy of a neighborhood a great deal nearer the New York City Hall than is the Hollender Hotel.

* * *

IF there is any remaining space for exhibits in the Hollender House at the time the Convention meets, it would seem as though late comers should get it at regular rates.

Resolved,

That Giving Out Incorrect Statements is Becoming Dangerous.

Casual Statements Don't Go.

At a meeting of the Board of Directors of the General Electric Company held in Boston on the 22d the following resolutions were adopted:

Whereas, Various printed statements (favorable and unfavorable) regarding the company and its business have heretofore appeared, most of them reading in a manner calculated to give the impression that they are issued either with the sanction of this company or from information furnished by its officers and directors, and

Whereas, In point of fact, and almost without exception, such statements are unofficial, and while often having some foundation in fact, are so inexact as to be to a great extent misleading; now, therefore, be it

Resolved, That the Board of Directors desires to caution the public against assuming that any casual statements, whether favorable or unfavorable, emanate from sources competent to furnish information respecting this company.

Resolved further, That the Board now states for the information of stockholders that the company is entirely free from floating debt. Since the date of the last annual report the company has purchased $1,127,000 of its debenture bonds, using for the purpose the proceeds of various accounts and assets which have been liquidated since the date of the said report.

What will the flunkeys of the daily press say to this? For months they have been printing all the stuff which came to them from "A director," "A man close to the management," "An officer of the company," etc., claiming large business, huge profits, retirement of bonds out of profits, 4 per cent. earned on the $34,000,000 of stock; and now the directors themselves, in solemn conclave, in the sacred city of Boston, have kicked holes in all the rosy pictures which have been drawn.

The financial writers have not been paid much for their puffery—perhaps an occasional cigar or a pat on the back from the Magnetic Man—and now the burden of deceit is thrown upon them.

We would like to hear an expression of honest opinion on these resolutions from the Boston *Advertiser*, the New York *Commercial Advertiser*, the *Recorder*, the *Wall Street Journal*, the Boston *News Bureau* and several others among our esteemed contemporaries.

As for ELECTRICITY, our work and our statements stand sure—indisputable and unanswerable.

We are not compelled to rely on either the casual statements of individual directors or the official reports of the Board. We get our information from the records of that concern, and they are better than "official"—they are correct.

But, after all, are not these resolutions a trifle mysterious? What director is it whose "casual statements" are unworthy of belief? Certainly not the one who told the Boston *Herald* that the bonds had not been retired out of profits, but out of the proceeds of assets sold. The "casual statements" of most gentlemen are as much to be relied on as any other statements. Whoever this rascal is he should be turned out.

The following from last week's issue of ELECTRICITY are worth reprinting:

(From Electricity, Jan. 2.)

But admitting that the debts are paid, that bonds have been retired, how has it been done? From profits in the business? Certainly not. They (the G. E. Co.) have sold during the year a large amount of local securities, have cleaned up a number of bad accounts, and with the proceeds from these two sources they have reduced their debts and retired some bonds.

(Inspired Financial Paragraph, Jan. 3.)

The allegation that the $1,000,000 bonds retired last year were not paid out of earnings is declared to be untrue, as the company now depends upon its earnings rather than new capital for all its expenditures. This has been true ever since the St. R. and Ill. Properties issue.

Twenty days afterward the honorable Board of Directors resolves that ELECTRICITY was correct.

"Since the date of the last annual report the company has purchased $1,127,000 of its debenture bonds, using for the purpose the proceeds of various accounts and assets which have been liquidated since the date of the last report."

The situation is encouraging. If our memory serves us correctly this is the first official information ever issued by the company for the enlightenment of the stockholders and the public, except in the annual reports.

Let the good work go on, Messrs. Directors. You have now answered one portion of one question asked in ELECTRICITY three weeks ago. Now answer the remaining portion of that question and a few of the others.

No casual statements, remember; nothing but official resolutions will go hereafter.

Some of the questions were as follows:

Have not the treasury assets sold during the year (including notes collected) amounted to more than the notes payable wiped out and bonds retired?

Did not the company lose practically $2.000,000 by the defection of the Fort Wayne Company?

Is it not liable for nearly $2.000.000 as a stockholder in Northwest General Electric?

Is there not a penitentiary job for some one if the affairs of the Northwest Company are ever aired in the courts?

Is it not a fact that the $8.000,000 of patent assets would be marked off the books in any honest company?

Are not half the $9,000,000 of notes receivable claimed in the last report worthless?

Was not the inventory account of last year carried at least $1.000,000 too high?

Could the stocks of manufacturing companies, carried at $2,700.000, be sold for $500,000?

Is a dividend possible for the next twenty years under present conditions of cost, selling expenses and price received?

Will not the next annual report show a further deficit of $6,500,000 at least?

Has not the gross business of the company fallen from $20,000,000 to less than $10.000,00, at the same time that selling prices have been reduced one half?

Has not the company paid out within 60 days nearly $70,000 to make good some of its guarantees on stocks and bonds sold to a financing company? What is the extent of the possible liability in this direction?

And another very important question to answer before the stockholders meet in April is:

Why were the United Securities Company and the Street Railway and Illuminating Properties allowed to return worthless securities to the G. E. treasury, taking in exchange therefor the best they could find, months after the original sale and agreement was made and signed?

And another:

By whose authority was the treasury of Northwest General Electric emptied?

These questions will probably be asked in a truly official manner before many months.

Personal.

Mr. Henry F. Kellogg, of the Whitney Electrical Instrument Company, Boston, was in New York last week in the interests of his company.

Mr. A. C. Garrison, secretary and treasurer of the Columbia Incandescent Lamp Company of St. Louis, is a visitor to New York this week.

A Richmond (Va.) paper states that Mr. Cecil P. Poole, general superintendent of the Lynchburg Electric Company, has tendered his resignation to the company for the purpose of accepting a position on the editorial staff of the *Electrical World*.

The Cleveland Convention.

The arrangements for the entertainment of the N. E. L. Association are in the hands of a well selected committee with C. W. Wason as chairman. The other members are: Myron T. Herrick, W. H. Lawrence, Horace A. Andrews, E. P. Roberts, F. De Hass Robison, Charles F. Brush, Robert Lindsay, W. B. Cleveland, S. H. Short, C. Corlett, J. P. McKinstry, M. A. Hanna, S. M. Hamil, C. H. Rockwell, J. Potter, Frank Billings, N. S. Possons, E. L. Babcock, Samuel Scovil, E. P. Sperry, A. V. Kurtz, George M. Hoag and S. C. D. Johns.

The criticism having been made that previous conventions had been rendered less beneficial to the attendants by outside attractions, it is proposed that the ensuing one be devoted more to business than pleasure; and it will be the aim of the committee, while omitting nothing that can contribute to the personal enjoyment of all, to give such direction to the proceedings as will tend to give them the fullest practical value.

National Electric Light Association.

The following bulletin is issued by the secretary in regard to the Cleveland meeting of the N. E. L. A.:

In addition to the list already furnished of papers to be read at the Cleveland meeting of this association, February 19, 20 and 21, there will be one by Nelson W. Perry, E. M., entitled "The Storage of Energy Essential to Central Stations: How it May be Accomplished and the Economies Resulting." Professor Langley of Case School, Professor Stine of Armour Institute, Chicago, and others, will take part in the discussion.

The topic, "How to Light Large Cities," will be discussed by Frederic Nicholls, Charles R. Huntley, Frank H. Clark, J. Frank Morrison, T. Carpenter Smith, George A. Redman, E. F. Peck and others.

The Brooklyn Electrical Society.

The Brooklyn Electrical Society will give an entertainment and *smoke*, January 31, at 815 Washington street, Brooklyn, the object being to raise funds for the establishment of suitable headquarters, library, etc., for the use of its members. Meetings are held at present at the Edison Assembly Rooms, Tuesday evenings, when papers are read and discussed.

When the necessary funds are raised to start the club-rooms, a library and laboratory and other conveniences are in order.

This idea will bring the individual members who are engaged in the various electrical branches of the trade, as well as steam engineers, into closer acquaintance with one another and so make the meetings more and more enjoyable.

Interior Conduit and Insulation Company's Annual Report.

The report of the above company presented at the annual meeting on January 17 shows a prosperous year for 1894.

The business of the year has been as follows:

Net sales Conduit Mfg. (Dept. "A")	$328.531.01
Net sales Electric Mfg. (Dept. "B")	206,181,33
Total net sales	$534,712,34
Gross profit	$101,768.85
Bad debts written off	756.14
Net profits	$101,012.71

The net sales for the years 1892, 1893 and 1894 were as follows:

Net sales, 1892	$356,061.06
Net sales, 1893	478,652.15
Net sales, 1894	534,712.34

A plan was presented to enable the company to increase its working capital $100,000, to make possible the adding of other lines of manufacture, thereby allowing the profits to be distributed among shareholders instead of being diverted to increased plant. This plan involves the reduction of the common stock from $1,250,000 to $1,000,000, and the issuing of $600,000 preferred stock.

It is the intention of the company to engage in the railway motor and generator business on a large scale, operating under the Johnson-Lundell patents.

COMMUNICATION.

THE NATIONAL SCHOOL.

To the Editor of ELECTRICITY.

DEAR SIR: The reply to your letter of December 21 has been unavoidably delayed on account of pressure of other duties. If you will consult the files of ELECTRICITY you will find published a letter from me, dated May 29, 1894, stating that my connection with the National School of Electricity is bona fide. Since that time I have no sufficient reason for discontinuing the same. I have assisted in the organization of classes in Minneapolis, St. Paul and Cincinnati. At each place the methods and purposes of the School were fairly and clearly presented. At each meeting I attended it was distinctly emphasized that the School did not claim or expect to produce trained electricians, but that it did intend to give the students a thorough grounding in the elements of the subject and open the way for them to grow into a better knowledge. In no case were the people told or led to believe that they could become famous inventors or engineers because of the knowledge imparted by the National School.

I hear occasionally from the classes in Minneapolis and St. Paul, and learn that the students are more than satisfied with the National School of Electricity. I have learned directly from the employers of some of those men that as one result of their study they have done much better work in the shop, and some of them have become efficient workmen who had been in imminent danger of discharge for incompetency.

I might say further that I am preparing the weekly lessons for the special courses among street railway employees, being engaged at present on Lesson No. 26 of the street railway course. The proofs of these lessons are sent to other members of the honorary faculty, and each week I receive copies returned by them with suggestions and criticism. The lessons are then revised in accordance with these suggestions and are then returned to Chicago where electrotypes are made for printing the copies which are sent out to the classes. I also receive proof copies of lessons prepared for the general course by Prof. Jackson and of the electro-therapeutic course prepared by Dr. W. J. Herdnan. These are returned with such suggestions as occur to me.

Very truly yours,

GEO. D. SHEPARDSON.

The University of Minnesota, Minneapolis.

Long Distance Transmission.

The Snoqualmie Falls Electric Power Company of Seattle, Wash., appends to its prospectus a letter from the Westinghouse Electric and Manufacturing Company in regard to the transmission of electric power over long distances which contains the following: "One of the oldest power transmission plants is that of the Roaring Fork Electric Light and Power Company, Aspen, Col., transmitting several hundred horse power three to four miles, about six years. The Gold King Mining Company, Telluride, Col., transmits 1,000 horse power ten miles, selling power to several stamping mills. The San Antonio Electric Light and Power Company transmits light and power fifteen miles to Pomona and thirty miles to San Bernardino, and the Portland plant transmits power from the Willamette falls to Portland, a distance of about fifteen miles. There are many more plants in operation and a large number in course of construction, the most important of which is the Niagara Falls plant, which will be 15,000 horse power to start with and will transmit power to Buffalo, twenty-two miles or over, and the company contemplates a much larger transmission when they have the nearer market supplied."

THE DISTRIBUTION OF ENERGY IN THE SPECTRUM OF THE GLOW LAMP.*

(PRELIMINARY MEASUREMENTS.)

BY EDWARD L. NICHOLS.

I.

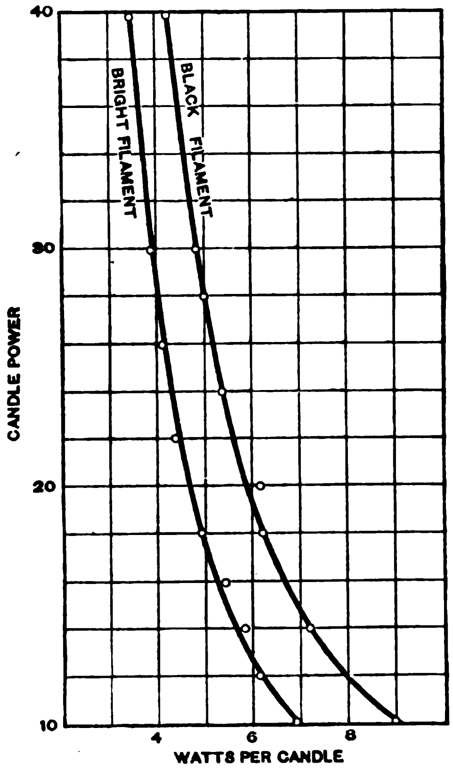
The glow lamp affords an interesting subject of study. In the first place, it is possible by varying the current in the filament to secure a very wide range in the temperature of the radiating surface, extending upwards to temperatures considerably higher than those of ordinary luminous gas flames, and to maintain more constant the condition of incandescence during the progress of each set of measurements than is possible in the case of any other source of light. In the second place, the study of the spectrum of the incandescent lamp affords an answer to certain questions of considerable practical importance.

In 1885, Messrs. Siemens & Halske, of Berlin, published the results of measurements for the purpose of showing the superiority of the silver-gray surface obtained by treating filaments of glow lamps by bringing the same to incandescence in an atmosphere consisting of volatile hydro carbon. In the following year Mr. Mortimer Evans† described comparisons of the radiation from bright and black incandescent lamp filaments in which the superiority of the former was very clearly demonstrated. Evans selected two filaments of similar size and structure, one of which he subjected to a surface deposition obtained by flashing in an atmosphere of ordinary coal gas, the result being a hard coating of carbon of the color of lampblack. The other filament was flashed in an atmosphere of volatilized hydro-carbons, by which means the usual silver-gray surface was obtained. The two filaments were then mounted and exhausted to the ten-thousandth of an atmosphere, and characteristic curves were made, showing (1) the relationship between the efficiency of the lamps, expressed in watts per candle, and candle power (see Fig. 1); (2) the relation between the total watts consumed in each lamp and the candle power. These curves show a very much greater amount of light for the energy expended in the case of the filament with bright surface.

Subsequently, two filaments of close, firm structure and of equal size were obtained which possessed the usual dull, dead black color resulting from carbonization without treatment. The characteristic curve of one of these was obtained after mounting the same in the usual manner and securing a good vacuum, after which it was removed from the lamp and was flashed in hydro-carbon vapor. After exhaustion it was again tested, measurements showing marked increase in efficiency; then it was removed from the bulb for a second time and flashed in coal gas, by which process a new surface of the color of lampblack was obtained. Having been remounted in this final condition and thoroughly exhausted for the third time, another characteristic curve was obtained. This curve was found to coincide quite closely with that of the original untreated filament. These three curves are given in Fig 2.

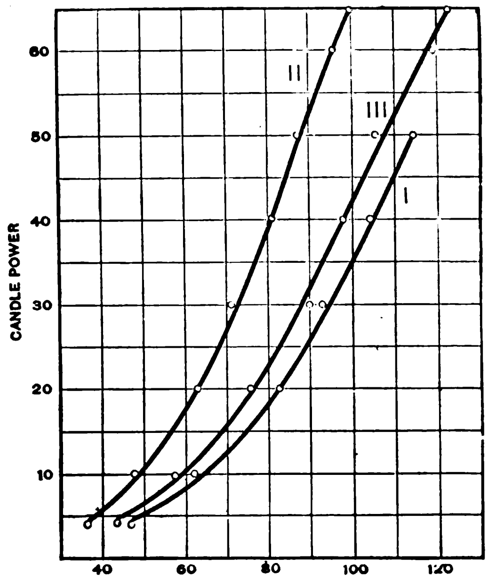
Mr. Evans's experiments seem to leave no question as to the fact that the bright surface obtained by flashing in hydro-carbon vapor possesses properties which fit it peculiarly for the production of light. Evans noted the fact that the lamp bulbs containing the black filaments were much hotter than those which surrounded filaments with a silver-gray surface, and he remarks: "I have little doubt that the loss of efficiency when black was due to the energy supplied being radiated in large quantities as heat waves from the blackened surfaces, which these surfaces when bright would not emit."

That the *total* radiating power of carbon in the form of lampblack is very much greater than that of the silver-gray graphitic form obtained by flashing in hydro carbons has been shown by H. S. Weber in a paper read before the Electrical Congress in Frankfort in 1891.* Weber, who tested thirty-three varieties of glow lamp filaments, found for the black carbon a coefficient of total emission lying between 0.0000169 and 0.0000174, and for treated filaments with bright surface, coefficients lying between 0.0000127 and 0.0000132.



Efficiency of Black and Bright Filaments (after Evans).

FIG. 1.



I. An Untreated Filament.
II. Same, after treatment (bright).
III. Same, after treatment (black).
(After Evans.)

FIG. 2.

During the winter of 1891-92, Mr. John C. Shedd† made a large number of comparisons of commercial lamps with treated and untreated filaments, for the purpose of further testing the conclusions reached by Evans. His method consisted in studying the visible spectrum of such lamps by means of the horizontal-slit photometer. The lamps were maintained for this purpose at various degrees of incandescence.

---

* "Physical Review."

† Evans, Proceedings of the Royal Society, Feb. 18, 1886.

* Weber, Verhandlungen des Internationalen Elektrotechniker-Congresses zu Frankfurt am Main, 1891, II, p. 49. See also "Physical Review," Vol. II.

† Thesis: In Library of Cornell University, 1892.

Mr. Shedd's results were in the main confirmatory of the higher efficiency of bright carbons, but they indicate clearly that the efficiency of the incandescent lamp is dependent upon other factors than the character and radiating power of the surface of the filament. He found, for example, that the vacuum especially has much to do with the relationship between the energy developed in the lamp and the candle power.

His comparisons between glow lamps, at different stages of incandescence, and the gas flame, bring out two facts which are of interest in the comparative study of treated and untreated filaments.

(1) Spectro-photometric measurements with lamps of untreated filaments of vegetable fiber showed that the light was of the same color as that from gas (in the argand burner) when the lamp was being operated at an efficiency of 6.8 watts per candle. All efficiencies lower than this showed relatively higher intensities in the red, while all efficiencies above 6.8 showed a light which was bluer than that of the gas. The relative intensities of the various wave lengths in the light emanating from such filaments were found to vary quite rapidly as the incandescence rose. Such a lamp, for which the ratio $\frac{\text{glow lamp}}{\text{gas flame}}$ for the region of the D line was unity, gave for wave length 0.4 μ about 1.6

(2) In the case of treated filaments with bright surface, on the other hand, equality with gas light as regards whiteness was reached only at somewhat higher efficiencies, viz., between 4 and 6 watts per candle. The changes in the color of the light from such lamps appeared, moreover, to be much less marked than in the case of filaments with black surface. The variation in quality, indeed, was frequently scarcely noticeable when the lamp was brought up from 7 to 4 watts per candle. It would appear from Mr. Shedd's measurements that in the case of black filaments the increase in the intensity of short wave lengths with temperature was much more rapid than in the case of the longer wave lengths; whereas with bright filaments all the wave lengths of the visible spectrum gained in intensity at very nearly the same rate.

II.

A study of the results obtained by Mr. Shedd made it evident to me that the influence of the vacuum of the glow-lamp was so great as to render all comparisons unsatisfactory between different lamps in which the pressure was an unknown factor. In the hope of overcoming this difficulty I had some lamps constructed, through the kindness of a friend engaged in the manufacture of glow lamps, by means of which this difficulty could be obviated.

Two lamp filaments as nearly identical as possible were taken. These were brought to identity as regards resistance by the usual method of flashing in hydro-carbon vapor; one of them was then given a coat of black carbon by smoking. They were mounted in bulbs of the usual form, the two being connected by a glass tube as shown in Fig. 3. The pair of lamps thus connected were placed upon a pump together, and were exhausted in the usual manner, after which they were sealed. These lamps could be brought to incandescence separately; but since there was permanent communication between the interiors of the two bulbs, whatever changes in vacuum occurred in the one would be shared by the other lamp.

Upon measuring the candle-power, voltage and current in the case of these two lamps throughout a wide range of incandescence and platting the characteristic curves, it was found that the difference in efficiency as expressed by watts per candle was very great indeed. The efficiency of the smoked filament was extraordinarily low. Inspection of the results obtained made the cause of this difference obvious, the fact being that the mantel of carbon obtained by smoking was of extremely high electrical resistance. The result was that when the same current was sent through the two lamps, the total watts generated in each were identical (see Fig. 4); but since the radiating surface of the smoked filament was very largely increased, the temperature of the lamp was greatly lowered. The consequence was that the black lamp required a higher voltage and a correspondingly greater amount of energy to bring it to a given candle-power than did the bright filament, which was without the superficial non-conducting layer of carbon. It seems probable that something of the same kind may have occurred to vitiate the experiments made by Mr. Evans, although, doubtless, the non-conducting film in the case of his lamps was much thinner than in the pair of lamps now under consideration. Although it was impracticable to compare these lamps with one another by the mere determination of the candle power and the watts per candle, they afforded excellent material for the study of the laws of radiation of these two widely different carbon surfaces. I accordingly subjected them to detailed measurements as regards the distribution of energy in the infra-red of the spectrum through a very wide range of temperatures, making use, for this purpose, of a method nearly the same as that described by E. F. Nichols in the first volume of this Review.* Indeed, in many of these measurements, Mr. Nichols did me great service, bringing to bear upon what was in many respects an operation of unusual delicacy the skill attained by long practice in a similar research.

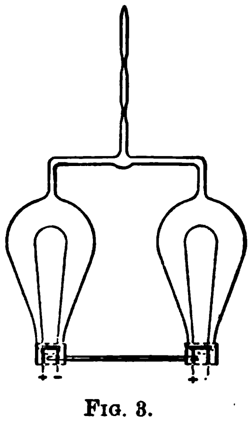


FIG. 3.

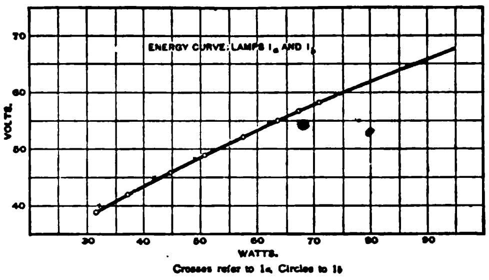

FIG. 4.

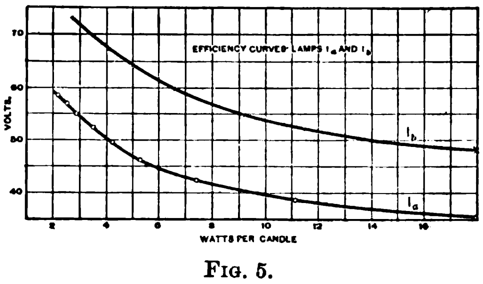

FIG. 5.

III.

The apparatus used in the study of the spectrum of these lamps was that described by Mr Nichols in the paper just cited. It consists of a spectrometer, in place of the eyepiece of which is inserted a linear thermopile of antimony and bismuth, the edge of which had been filed down until only a very narrow strip was exposed to radiation. Dispersion was obtained by means of a prism of carbon bi-sulphide contained between glass walls. This substance was selected because there is reason to believe that it obeys more closely than any other available material Cauchy's law for dispersion.

The use of the spectrometer with glass lenses, and of a prism the walls of which are of glass, in the study of the distribution of energy in the spectrum, is open to the serious objection that both glass and carbon bi-sulphide exert selective absorption upon the rays of light which pass through them. The only substitute for a prism and lenses would be a concave grating, or a plane grating used in connection with a concave mirror. The feebleness of the spectra produced by means of the grating offers in itself a serious hindrance to its use in bolometric work. The theory of the diffraction grating, as given by Rowland, is, moreover, conclusive as regards the unfitness of ruled gratings for the determination of energy in the spectrum, and it had been previously shown experimentally by Paschen that the exploration of the spectrum of incandescent lamps by means of the grating and bolometer led to results which were full of the most serious errors. No more striking verification of the theory can be given than the curves exhibited in Paschen's paper. So serious, indeed, are the vagaries of the diffraction grating in this respect that it would seem as though all work involving absolute measurements of the distribution of energy in the spectrum, in which diffraction has been made use of, must be discarded and the work done over by other methods.

As regards the fitness of the material used in the apparatus with which the experiments to be described were made, it may be noted that Angstrom has studied the absorption of carbon bi-sulphide in the infra-red and has found it to be transparent as far as wave length 3.0 μ, beyond which lie two strong absorption bands. Since, however, my measurements do not extend beyond 3.0 μ, there seems to be every reason to assume that no serious errors will be introduced by the passage of the rays under investigation through this medium.

Ernest Nichols, in the article just cited, has studied the diathermacy of glass. His curve for the percentage of light transmitted by a plate of glass (see "Physical Review," Vol. I, p. 8) indicates great uniformity in this material up to the longest wave lengths to be considered. The diminution of light due to the interposition of the specimen of glass which he tested is scarcely greater than the losses by reflection at the two faces of the plate, and while there is evidence of very slight decrease in the transmitting power as we pass from 2.0 μ to 3.0 μ, the change cannot amount to more than one or two per cent. Under these circumstances, it seems quite safe to assume that no serious errors will result from selective absorption of the rays of the infra-red spectrum of glow-lamps, either by the glass of the lenses and the walls of the prism, or by the contents of the prism itself.

The most serious objection to the use of the bi-sulphide prism lies in the fact that the dispersion is very small for the longer wave lengths. The shortening of the spectrum in the infra-red is such that measurements beyond wave lengths μ are of questionable value.

---

* Nichols, "Physical Review," Vol. I, p. 1, 1893.

The choice of the thermopile, the width of the face of which was something more than half a millimeter, instead of a more strictly linear instrument such as the bolometer, is open to criticism. In point of fact, the thermopile showed itself to be so much more sensitive than any bolometer which Ernest Nichols and the writer were able to construct that we were led to adopt it in spite of this objection. It seemed quite certain, moreover, that there was but little of interest to be found in the spectrum of glow-lamps beyond the regions which it was possible to explore with the thermopile, so that it did not seem worth while to expend a great deal of time in the construction of a bolometer.

Our experience appears to differ from that of others who have worked in this field; but it may not be without interest to state that we both tried bolomoters constructed of the platinum cross hair wire, used by Snow in his exploration of the bright line spectra of the alkalies—an investigation which would seem to demand the very highest delicacy; also bolometric strips of iron, nickel, aluminium, etc. We were not able within the time at our disposal to construct a bolometer the sensitiveness of which for the purpose of our measurements was greater than one-twentieth of that of the linear thermopile.

The galvanometer used in these studies was he one briefly described by Ernest Nichols in his article already cited. It was built in the instrument shop of the department by F. C. Fowler, but the moving parts were made by Mr. Nichols, to whom also I owe the very careful study of the bi sulphide prism.

(To be continued.)

ON THE UNITS OF LIGHT AND RADIATION.*

BY A. MACFARLANE, D.SC., LL D.

One of the recommendations made by the subcommittee of the Institute in the programme for the International Electrical Congress at Chicago was that the practical unit of illumination should be defined as the illumination produced by the bougie-decimale at the distance of one meter, and that this unit should be denominated the bougie-meter. To this definition little objection was made, excepting that Prof. Nichols pointed out that it involved an arbitrary standard of light which had no relation to the C. G. S. system of units. More general objection was taken to the notation for the unit.

The London *Electrician* for February 3, 1893, objected to the "bougie-meter," that all other such compound names imply a product of the components, while in this case the former component is divided by the latter, or, more correctly, multiplied by the square of its reciprocal; and suggested, half seriously, that instead of 'candle-foot" we ought on the "mho" principle to speak of "candle toof-toof."

M. Hospitalier made the same objection, that "bougie-meter" according to existing usage means a product, and suggested "bougie-at-a-meter," or, if that were inadmissible, the use of a new term such as "lux." M. Blondel favored the single term "lux," and Mr. Lockwood the single term "davy."

Consider the philosophy of the substitute suggested by the *Electrician*. If we attempt to formulate the "mho" principle we find that it may be expressed as follows: The reciprocal of a given unit may be denoted by writing the name for the direct unit backwards. It supposes that the given unit can be expressed as the ratio of two other units; thus, ohm is the single name for the ratio, volt per ampere. The reciprocal idea is ampere per volt, and there is a convenience in not introducing a new and independent word, but in denoting it instead by the direct term written backwards.

It appears to the writer that here we have a principle which might well be adopted in mathematical analysis, for we have all felt the want of a suitable notation for a function which is the reciprocal of a given function; for example, the reciprocal of *tan* or *sin*. English and American writers use tan^{-1} and sin^{-1}, a notation which is half word, half symbol, which cannot be pronounced, and which suggests the reciprocal quantity instead of the reciprocal function. Continental writers use "arc tan" and "arc sin," which are too long and periphrastic. On the "mho" principle, the reciprocal of "tan" is "nat" and that of "sin" is "nis." Let $x = \tan y$, then $y = \text{nat}\, x$; let $a = \sin b$, then $b = \text{nis}\, a$. According to Lord Kelvin, who, I believe, introduced the "mho" notation, the expression for a function should consist of three letters; and, it may be added, the middle letter ought to be a vowel, the other two consonants. Such a syllable notation when inverted remains a syllable. This notation would have the advantages of being short, unambiguous, articulate and logically connected.

But in the case of a fundamental unit, such as the foot, is there any reciprocal idea? It is true that there are physical quantities which have the dimension l^{-1}; but on examination they will be found to express a physical ratio of some kind. For example, the unit of curvature has the dimension l^{-1}; it is expressed by radian per foot. The reciprocal unit is foot per radian, having the dimension l; it is not a measure of length, but of flatness.

The difficulty experienced in expressing the intensity of a candle or other spherical source arises from the want of a name for the unit of solid angle. Just as the natural unit for plane angle is meter of arc per meter of radius, so the natural unit for solid angle is square meter of spherical surface per meter of radius squared. The name "radian" given to the former unit (Everett's "Units and Physical Constants," 1879) has been very useful in expressing exact ideas; a recognized name for the latter unit would also be highly useful. For this purpose the word "steradian" was introduced by Dr. Halstead in his Metrical Geometry in 1880, and I have used it in my work on Physical Arithmetic. Though not faultless from the point of view of the etymologist, it is sufficiently expressive to the physicist.

How, then, is the unit of illumination properly expressed? Suppose that by "bougie" is meant the current of light which streams from a uniform standard candle through one "steradian," then the illumination anywhere may be expressed in terms of bougie per square meter, where the former component refers to the current and the latter to the cross-section. But in the case of light streaming from a point source, the illumination may be expressed in terms of (bougie per steradian) · (steradian per square meter), where the former component refers to the intensity of the source, and the latter to the solid angle subtended at the source by one square meter of cross section. If "lux" is the single term for this unit we have

lux = bougie per square meter
=(bougie per steradian) · (steradian per square meter).

Hence, candle per square foot or (candle per steradian) · (steradian per square foot) is the proper expression for the candle-toof-toof of the *Electrician*.

According to the above definition of "bougie," the total current from the candle would be 4π "bougies." But if "bougie" is defined to mean the total current from the candle, and by "lux" is meant the same quantity as before, we should have

$$\text{lux} = \frac{1}{4\pi} \text{ bougie per square meter.}$$

We cannot logically avoid the 4π; exclude it from the source, it appears in the intensity, and *vice versa*. This point is overlooked in the established system of magnetic units, and forms the basis of Heaviside's rational system.

The use of the hyphen to denote a product unit is not very appropriate, for it suggests the sign minus rather than the sign of a product. It would be better if it were omitted altogether and the two component units amalgamated as in footpound and kilogrammeter; for then the nomenclature would correspond to the algebraic convention which leaves the sign × to be understood, and in addition the hyphen would be set free to denote any compound unit other than the product or quotient.

If we consider the general subject of radiation we shall be led to distinguish the following ideas with their corresponding units:

TABLE I.

Idea.	C. G. S. Unit.
1. Quantity of radiant energy	Erg.
2. Current	Erg per sec.
3. Strength of source	Erg per sec.
4. Intensity of spherical source	Erg per sec. per steradian.
5. Intensity of cylindrical source	Erg per sec. per (cm.-radian).
6. Intensity of plane source	Erg per sec. per cm².
7. Density of source	Erg per sec. per cm².
8. Intensity of current	Erg per sec. per cm².
9. Time flow	Erg per cm².

Quantity of radiant energy of whatever kind can be expressed in ergs, and a *flow* in ergs per second. By *strength of source* is meant the whole quantity of radiant energy which leaves the source in a given time divided by the time; the appropriate unit is erg per second. The *intensity of a source* is differently expressed, according as the radiation is spherical, cylindrical, or plane. In the first case it is the ratio of a current through a solid angle to the solid angle, and hence it is appropriately measured by the erg per second per steradian. In the second case it is the ratio of a current through a wedge-angle to the wedge-angle. There is no recognized unit of wedge-angle, as it involves the radian in one plane and a length along the perpendicular to that plane; it may be expressed by cm.-radian. Hence the intensity will be expressed in erg per second per (cm.-radian). If the radiation proceed from an infinite plane, its intensity is measured in terms of erg per second per cm².

By the *density* of the radiation at any point of a source is meant the ratio of the flow normal to a small surface to the small surface, and is expressed in terms of erg per second per cm². By *intensity of current* anywhere, is meant the ratio of the flow through a small cross-section to the cross-section, and is also expressed in terms of erg per second per cm². By *time flow* is meant the ratio of the energy which has passed through a cross-section to the cross-section. It is expressed in terms of erg per cm².

---

* Paper read before the American Institute of Electrical Engineers, January 16.

TABLE II.

Idea.		Unit.	Symbol.
French.	English.		
1. Quantité de lumière...	Quantity of light..........	Rad.; lumen-hour...........	Q
2. Flux lumineux...........	Luminous flux..............	Lumen......................	F
4. Intensité lumineuse.....	Luminous intensity.........	Pyr........................	I
7. Radiation Intrinseque.	Intrinsic radiation........	Lumen per cm²..............	R
8. Eclairement.............	Illumination...............	Lux........................	E
9. Illumination............	Quantity of illumination..	Phot.......................	L
Eclat intrinseque.........	Intrinsic brightness.......	Pyr per cm²................	E

The above is the appropriate system of C. G. S. units for any kind of radiation measured simply as energy. But in the case of light the eye exercises a selective power, not only singling out a certain range of wave-lengths, but discriminating among them as to amount. If one of the units is defined with reference to this discrimination exercised by the eye, then the other units of the light system can be defined in terms of it, and the units of length and time.

Recently M. Blondel has published (*La Lumière Electrique*, July 7, 1894,) an ingenious and logical system of units of light with corresponding practical units. When the ideas are arranged in the same order as in Table I, we obtain the system exhibited in Table II.

By "pyr" is meant a luminous intensity equal to one-twentieth part of the luminous intensity of the Violle standard. By "lumen" is meant the current of light through a steradian, the spherical source having a uniform intensity of one pyr; that is,

lumen = pyr-steradian.

By "lux" is meant the illumination produced by a current of one lumen falling perpendicularly on a surface of one square-meter; hence,

lux = lumen per square meter.

The idea of No. 9 is expressed in French by illumination, but this word in English means éclairement; hence it has been proposed by M. Hospitalier to introduce "lumination" into both the French and English languages to express the idea in question.

The "phot" is defined as equivalent to "lux-second." By "rad" is meant the unit of quantity of light. It is defined by

rad = lumen-second

just as the coulomb is defined by

coulomb = ampere-second.

The "phot" and the "rad" are said to be of special use in photography. But it may be asked whether the actinic system of units is not independent of the optical system. Is not the "pyr" then defined by the actinic effect instead of the optical effect? If so, we have two complete systems of units, both different from but parallel to the radiant energy system.

M. Blondel does not introduce Nos. 3 and 5. Let "bougie" denote a spherical source having a uniform intensity of one pyr; then we would have

$$\text{bougie} = 4\,\pi \text{ lumens.}$$

The symbols given in the last column of Table II have been proposed by M. Hospitalier, and he asks for criticisms. In the system of symbols and abbreviations recommended by the Congress, all quantities are denoted by oblique letters or script letters, and units and abbreviations for units by perpendicular letters. The proposed symbols, from their perpendicular character, will not harmonize well with the other symbols of quantity. Also they are already in use to denote vector quantities.

The Northwestern Electrical Association's Annual Convention.

The annual convention of the Northwestern Electrical Association, at Milwaukee on January 15 18, was attended by nearly 100 members, and those who were fortunate enough to be present found much to enjoy in the proceedings incident to the occasion. The papers submitted included "Interior Conduit and Interior Winding," by Charles E. Burton; "Hints Upon Daily Work About a Dynamo Plant," by Pliny Norcross; "Incandescent Lamps vs. Welsbach Burners," by William Goeltz; "Some Characteristics and Economies of Accumulators as Applied to Central Lighting and Power Stations," by John R. Markle; "Incandescent Lighting on the Meter System Compared With the Contract System," by G. L. Cole; "Competition," by John Schuette; "Electrical Business," by C. E. Gregory; "College and Station," by Prof. D. C. Jackson; "Common Councils," by P. K. Korst; "Water Power," by G. A. Davis, and "Profits," by Geo. Grimm.

President C. C. Paige's address at the opening session dealt disparagingly with governmental ownership of railroads, telegraphic, electric and kindred public services, and particularly with oppressive municipal enactments which fettered enterprise.

The following officers were elected for the ensuing year: President, H. C. Thom, Madison; first vice-president, George Grimm, Jefferson; second vice-president, Pliny Norcross, Janesville; secretary, William Goeltz, Milwaukee; treasurer, John Schuette, Manitowoc; directors, F. A. Copeland, La Crosse; E. M. Highland, Clinton, Ia., and O. M. Rau, Milwaukee.

On the second evening a banquet was provided at the rooms of the Deutcher Club, and the last day was taken up with visits to the great breweries and electric light stations.

The following new members joined: George S. McLaren, C. D. Wyman, John D. McLeod, Milwaukee; H. C. Higgins, Marinette; A. A. Forman, Iron Mountain, Mich.; C. D. Wilkinson, Chicago; W. F. Collins, Wausau; Willis D. Jameson, Chicago; J. W. White, Peoria; Richard A. Dix, Wauwatosa; E. P. Ingham, Fargo; Fort Atkinson Lighting Company, Fort Atkinson; James Montgomery, Wausau; J. E. Heaton, Reedsburg; Charles W. Rodman, Ravenna, O.; Hiram Stedman, Berlin; J. Wolff, Max A. Berg, J. H. Cooke, Chicago; Lewis Brittain, Waukegan; G. H. Strong, Richland Center; E. M. Highland, Clinton, Ia.; F. S. Copeland, La Crosse; M. B. Austin, Channing T. Gage, John Valentine, R. H. Pierce, Chicago; M. A. Warren, Baraboo.

BOOK REVIEWS.

ELECTRIC POWER: A Monthly Magazine devoted to the Theoretical, Mechanical and Financial Interests of the Electrical Transmission of Power. HORATIO A. FOSTER, Editor; MAX OSTERBERG, Associate Editor. 96 pp. $2.00 per year; 20 cents per copy. Publication office, 36 Cortlandt street, New York.

For some time past the reading public have been on the *qui vive* for the appearance of our old friend, *Electric Power*, in magazine form. The new magazine, for such it practically is, is now at hand and fully justifies the high expectations aroused for it. The question as to whether or not the time was ripe for an electrical magazine has agitated the minds of many for several years. Many have thought that it was, and several attempts have been made to fill the aching void, but the results in such cases have seemed to indicate that the aching void either did not ache very much or the panacea that was applied was not suited to that particular kind of an ache.

The writer has been one of those who, having given this subject much thought and study, came to the conclusion that the time *was* ripe for the right kind of magazine, and although he has not been one of those who have attempted to fill the bill, he is one of the many who will rejoice when the bill is filled. We have believed that a thoroughly high-grade publication conducted on liberal lines would pay. We have believed that well-matured editorial views covering the events of a past month, and especially the living questions of the day, should form a most valuable feature which the weeklies in the unavoidable rush to get to print cannot hope to fulfil in any complete measure. We believe that such editorials to have the highest value should not all emanate from the same mind, for one man's opinions, however valuable they may be in the direction of his specialty, cannot be of equal value in other directions. It would therefore be the province of the editor-in-chief to select editorial writers specially competent to speak on questions on which he might not be fully informed. We do not recall a single technical or semi-technical magazine of to-day in which the editorial page has sufficient merit to make its omission entirely a noticeable loss. With the weeklies not so much is expected, and the shortcomings of the editorial page are therefore less marked. We have thought, and still think, that in this direction lies the greatest chance for improvement. It is a field at present practically unoccupied, and one which if judiciously and properly worked should be more prolific of good results than any other now open to the electrical editor and publisher.

None of the sciences are so closely and tangibly interwoven with our everyday lives as the comparatively new one of electrics. It may be truthfully called *the* popular science, and in its ramifications and extensions may be called the science of *doing*, the science of *seeing*, the science of *hearing*, and when electro-therapeutics has thrown off its swaddling clothes it may prove itself the science of *being*.

The exponent of this science to meet the popular demand should therefore take on the garb of the people, and, so far as is consistent with strict accuracy of statement, speak in the language of the people. Its function in the science should be that of Franklin's kite and string in the lightning experiment, viz., to bring it down out of the clouds that we may see what it is and understand its nature. Severely technical articles should have no place in such a magazine, nor have they, we conceive, in the weeklies. Such articles have indeed an immense value among a certain limited circle, but their place is in the

Transactions of those societies composed of individuals who can understand them.

It has always seemed to us somewhat in the nature of an imposition for a journal that depends for its subsistence upon a constituency largely composed of manufacturers and laymen, in contradistinction to scientists, to offer them week after week and month after month pages and pages of the most abstruse mathematical logic, which none care to understand even if they were qualified by training to follow the reasoning out to its end, and then as a sop to this very class print page after page of free advertising puffs which too often express no one's opinions, not even those of the one they are intended to benefit and in whose handwriting the original copy most often is.

The bane of electrical journalism as it exists is its subserviency to supposed trade considerations. The editor is less to blame for this than the powers behind him, but the pressure is so great that he may not speak his mind without first looking around to see whom he is going to hit, and if he finds that he is an advertiser or a possible advertiser the truth must be left unsaid. This condition has become so engrafted upon trade journalism that it is probably too much to expect its abolishment at this late day, but in a monthly magazine it has no place and there is no excuse for it. In fact a monthly electrical magazine cannot be a trade journal and succeed.

In *Electric Power* in its magazine form we find the nearest approach to our own idea of what such a journal should be of any of the attempts thus far made in this direction, and the personnel of the editorial staff as well as that of other departments is such as to inspire the utmost confidence in a continuance of the good promises held out by the prospectus and the first issue. We therefore welcome the coming of this new aspirant for public favor and bespeak for it all the success which it may deserve.

THE NEW SCIENCE REVIEW: a Miscellany of Modern Thought and Discovery. Quarterly. Single numbers, 50 cents; per annum, $2. New York, London, Philadelphia: The Transatlantic Publishing Company.

In the announcement of the above we find the following:

> There are many scientific periodicals. "The New Science Review" differs from all of them. It is new in every sense—new in its appearance, new in its methods, new in its aims. It does not attempt to supersede the older and more conservative periodicals, but to supplement them. Those address themselves to the specialist, this to the public at large. While yielding to none in the scientific value of its material, it strives to present it in a popular style. It does not assume that the reader already has an esoteric acquaintance with the matter in hand and start from that standpoint,—it supplies him with a standpoint; it explains before it demonstrates. Thus it occupies a position midway between the ponderous scientific journals and the lighter magazines. It is as valuable as the first, as interesting as the latter. But it conflicts with none. It has a distinct individuality.
>
> The quarterly method of publication has been chosen because it has been thought that this affords ample time for the exploitation of every new theory, invention or discovery that may hold the public attention during the interim. When "The New Science Quarterly" speaks, it will speak with authority. It will have weighed the evidence impartially. Its decisions, if not infallible, will be in accordance with the latest development of modern thought.

That there is a field for a periodical planned on the lines indicated above no one will deny, and it was with anticipations of pleasure that we awaited the appearance of the first issue in July. "When 'The New Science Quarterly' speaks, it will speak with authority. It will have weighed the evidence impartially. Its decisions, if not infallible, will be in accordance with the latest development of modern thought." These words implied much,—led us to expect much—perhaps too much to render possible the full realization of our expectations. We were prepared for disappointment, but not for such as we experienced in looking over the first number, for here we found twenty-seven pages of good paper devoted to a defence of Keely and his motor, entitled "A Newton of the Mind." This is from the pen of Mrs. Bloomfield Moore, who, it will be remembered, came into notoriety not long since through the publication of a book on the same subject. We paused to ask, in face of the announcement, "Are Mrs. Bloomfield Moore's views on the Keely motor and mechanics in accordance with the latest development of modern thought?" and we answered ourselves that we hoped not.

The publication of this article in the initial number was enough to condemn the magazine for all time with intelligent people, but we withheld criticism, wishing to give to our contemporary opportunity for reflection and a chance to do better.

The second number was a decided improvement in that it not only contained considerable really good matter, but the bosh and trash that so characterized the initial number was largely absent. Our hopes were raised again and we were preparing to say a kind word for our new contemporary when, alas! the January number made its appearance. In its table of contents appear four titles which at once attracted our attention —three of them on "What Electricity Is," by Mrs. Bloomfield Moore, C. J. Reed and Henry Clay, and another, "Pre-Scientific Electricity," by Horace Hayden, Jr. The latter is indeed a very readable article and well fulfils the promise of its title. But the first three—well! we know who Mrs. Bloomfield Moore is, and we are not surprised that it is the Keely motor she is talking about instead of electricity. We don't know who C. J. Reed is, but in trying to criticise an anonymous writer in the October issue, who offered some suggestions as to the nature of electricity, he gets hopelessly mixed up in his chemistry and contributes nothing to our knowledge of the subject in hand. Henry Clay we do know as a historical character of great prominence in the United States in years gone by, and we presume that the present contributor is his materialized spirit. We come to this conclusion for the reason that it is of the general character of other reputed spirit communications from great men—meaningless and trivial.

There are always a lot of cranks who think they have, or try to make the world think they have, at one fell swoop upset modern philosophy, and they usually pride themselves upon presenting unanswerable arguments. Their arguments are unanswerable usually for the reason that they present nothing to answer, but they themselves cannot see this. They fondly imagine that they are leaders of modern thought, and if this class of literature, such as Mrs. Bloomfield Moore and the shades of Henry Clay are contributing, is "in accordance with the latest development of modern thought," then "The New Science Review" is fast gaining a reputation as an exponent of it; but we fancy that the few responsible writers who, misled by the prospectus to believe that the "Review" was to be conducted on rational thought, have contributed to its pages, will ask to be counted out in future issues. Certainly if "The New Science Review" is to be the organ of those believing in the doctrine of Keely *et id genus omne*, as seems probable from the issues now before us, reputable writers who have reputations to lose will keep out of it. We believe that "The New Science Review" has committed suicide by the admission to its pages of such scientific rot as that which is offered as argument or reason in the articles by Mrs. Bloomfield Moore and Henry Clay. If this is the best it can offer in the way of modern thought, it cannot be buried too soon.

London Notes.

(From our London Correspondent.)

Transformer Chambers in Public Streets.

Within the past few months there has been a nervous and unnecessary outcry in London against electricity supply companies being allowed to erect transforming chambers under public thoroughfares. The parties who protest against these powers being possessed by the companies are the London County Council and a number of public bodies governing districts in the suburbs of London. The Board of Trade was appealed to to take some steps in the matter, and accordingly arranged for a conference which was duly held in the middle of December last. Expert evidence was given by Dr. John Hopkinson, Sir Benjamin Baker, Mr. James Enright (of St. Mary's College), Prof. Henry Robinson, Sir Frederick Bramwell, Prof. Silvanus P. Thompson, Dr. J. A. Fleming, Mr. A. J. Lawson and others.

The Board of Trade has since gone very fully into the matter, and the result of its inquiry, which is now published, is that it has adopted the advice given by Sir Courtenay Boyle, that if proper precautions are taken to secure the public safety the department would not be justified in forbidding the use of transformer chambers in the way suggested. This seems the only reasonable decision that could have been arrived at. Any other decision would doubtless have hindered the progress of electric lighting, and the Board of Trade appears to have no particular desire in that direction.

What with transformer chambers and light railway conferences, and the inquiries regarding the main box explosions in Cannon street and St. Pancras districts, the Board of Trade is very busy in electrical matters. As the outcome of the inquiries into the cause of these explosions the London County Council now proposes that plans for street boxes should be approved only on the condition that provision is made for their adequate ventilation.

LECTURES ON THE ELECTRIC CURRENT AND THE ARC LIGHT.

The lecture season is now in full swing. Prof. J. A. Fleming has been interesting juvenile audiences at the Royal Institution of Great Britain with a course of six lectures on the "Electric Current." These lectures attracted very full audiences on each occasion. They were delivered in popular language and illustrated by simple experiments, including some of Faraday's.

Prof. Silvanus P. Thompson commenced on January 14th a series of three Cantor lectures before the Society of, Arts on the "Arc Light." In his first lecture the Professor, after remarking that much about the electric arc is still very obscure and little understood, discussed when and by whom it was first observed, and came to the conclusion that in the first year or two of this century Davy and other investigators found they could get sparks visible in daylight between well-burnt charcoal points connected each with a pole of the newly discovered voltaic pile. These early experimenters did not clearly discriminate between a continuous arc and a succession of sparks, but in 1808 this distinction was certainly known. In 1820 the hard carbon deposited in gas retorts came into use, and in 1846 the first mechanical arc lamp was devised. Professor Thompson then exhibited the arcs formed between various metals, and briefly pointed out their different characteristics. He afterwards confined his remarks almost entirely to the arc produced between carbon conductors, carbon being the only material as yet known that is suitable for the industrial production of the electric light. He then proceeded to consider the physics of the arc. He discussed the conditions necessary for its formation, the point from which the greatest light is emitted, the relations between electromotive force and length of arc and between amount of current and size of arc, the temperature of the crater, the fall of potential in the arc, and the question of the transfer of material from one carbon to the other, concluding, with regard to the last point, that material is transferred in one direction only—from crater to peak. He then showed an arc formed by an alternating current of 2,000 volts, though this, he said, was not a true arc, but of the nature of a flame. In the true arc there is combustion of the air with the production, as Professor Dewar has shown, of carbon monoxide and dioxide, and of various nitrous compounds, whose smell may sometimes be noticed.

LEGAL NOTES.

Interior Wiring Patent Decision.

The United States Circuit Court of Appeals, New York, Judges Lacombe, Wallace and Shipman presiding, on the 22d inst. confirmed the decision of Judge Coxe in the case of the Interior Conduit Company against the Eureka Electric Company, denying the application for injunction. Complainants' claims were, in brief, as set forth in the following:

"1. In house-wiring for electric light, the combination of a pipe of insulating material, a pair of wires insulated from each other and placed in close proximity to each other within said pipe, and each forming one side of an electric lighting circuit, and a safety catch interpolated in said circuit, substantially as set forth.

"3. In house-wiring for electric light, the combination of a pipe of insulating material, a pair of insulated wires twisted together within said pipe, each wire forming one side of an electric lighting circuit, and a safety catch interpolated in said circuit, substantially as set forth."

Judge Coxe had said in summing up his opinion:

I have examined the patent with care to discover what new idea it has contributed to the art, and am compelled to think that the art of electric lighting would have lost nothing tangible if the statements of the patent had never been made public.

Judge Call has rendered a decision refusing the motion for an injunction in the suit brought by the Jacksonville Electric Light Company against the city of Jacksonville, Fla. The suit was based principally on the ground that the General Electric Company's bid for an electric lighting plant for the city was not the lowest, and that plaintiffs' contract with the city barred the city against engaging in the lighting business.

Chancellor McGill, of New Jersey, has denied the application of Samuel K. Wilson for a receiver for the Trenton Passenger Railway Company, and the company has now brought suit against Mr. Wilson for $160,000 which it claims he owes it.

In the U. S. Circuit Court at Boston, on the 22d inst., Judge Carpenter overruled the plea in bar set up by the respondent in the equity suit of the Westinghouse Electric and Manufacturing Company against William Stanley, Jr. The defendant will have to answer the complainant's bill. The suit is brought for an injunction to restrain the defendant from an alleged infringement upon patent No. 469,809, granted March 1, 1890, for an improvement on the system of electrical distribution.

A suit has been filed in the U. S. District Court at Detroit, Mich., by the Detroit Motor Company against the Jenney Electric Motor Company of Indianapolis. In the complaint the plaintiff alleges that Harry H. Blake is the inventor and patentee of an electric switch for motors and that he sold the invention to the Detroit Motor Company. The plaintiffs allege that the Jenney Electric Motor Company has infringed their patent, and they ask for damages and an injunction against the company.

Boston Notes.

Several new red range lights for the use of captains of vessels entering Boston harbor are about to be erected. They are in every instance to be electric lights, and bids for their erection will shortly be called for by the Lighthouse Board.

The well known fixture manufacturing firm of Horn & Brannen Co., of Philadelphia, has been awarded the contract for equipping with gas and electric fixtures the new and handsome public building at Lowell, Mass.

Some of the suburban electric light companies are being badly mixed up just now and are being placed in the hands of receivers or being wound up in other ways owing to their inability to pay interest on their bonds. These different concerns are among the undertakings established by the T.-H. Company a few years ago, when they were in the heyday of popularity as "financial wonders." It is likely that at the approaching town meetings which are held in March more than one lighting contract will fail of renewal, which means the closing of the papier-maché concerns.

The New England Telephone and Telegraph Company has announced that after February 1 next it will offer to subscribers for telephone connection and service in its Boston and suburban exchanges, measured service rates, with metallic circuit and long distance wall equipment, within one mile of the central office, which are likely to prove very acceptable to subscribers, as they will thereby secure excellent service of a special character at much below regular rates.

The fifth annual ball of the Massachusetts Electrical Engineers and Mechanics' Association, held in Odd Fellows' Hall on the evening of the 21st, was a brilliant success. The immense building was gorgeously illuminated, both on the exterior and interior, by several thousand colored arc and incandescent lamps. By the means of an immense switchboard, constructed for the purpose, some singularly beautiful effects were produced in the ball room, which was a blaze of vari-colored lights. There were nearly 2,000 guests present, and dancing was kept up until four o'clock in the morning.

A spirited effort is now being made in the State Legislature to kill the entire subway project for Boston. Should its opponents succeed, public opinion will once more be directed to the reconsideration of the Meigs overhead electric railway plan. Meantime Boston is paying out money lavishly for a solution of the rapid transit problem.

There is likely soon to be an important consolidation of electric railway interests in the northeastern part of Massachusetts. If it is consummated, it will be one of the biggest railway deals for some time. The company will have $2,000,000 capital, 150 miles of track. Boston would be in direct electric communication with Newburyport, some forty-five miles away, and all intervening and adjoining cities and towns would be included. A number of wealthy capitalists and prominent railway men are interested, and the deal is likely to go through.

The Berlin Iron Bridge Company.

The Berlin Iron Bridge Company, of East Berlin, Conn., have closed their purchasing agent's office in Philadelphia, and hereafter all purchases will be made from the office of the company at East Berlin. Mr. W. E. Stearns, who lately occupied the position of purchasing agent, has severed his connection with the company and accepted a position with the Pennsylvania Steel Company.

Redlands, Cal.—The Redlands Electric Light and Power Company has voted to issue $100,000 in bonds, $50,000 of which is to be used in taking up the original bonds, and $50,000 to be spent in permanent improvements.

General News.

What is Going on in the Electrical World.

Phillipsburg, N. J.—$18,000 is said to be already pledged for the establishment of an electric lighting plant in this town.

Newport News, Va.—Preparations are being made for important extensions of the electric railway system in this place.

Gladstone, Mich.—A committee of the city council has been appointed to secure estimates on the cost of a municipal electric lighting plant.

Three Rivers, Mich.—The village council have under consideration the question of establishing an electric light plant to be owned by the village.

Lansing, Mich.—A bill is to be introduced in both branches of the Legislature providing an appropriation for an electric light plant for the Capitol building.

Bayonne, N. J.—The council has passed an ordinance granting a franchise to the Hudson County Electric Company to establish an electric light plant in Bayonne.

St. George, S. I.—The officials of the Staten Island Rapid Transit Company are considering the advisability of changing their motive power from steam to electricity.

Corsicana, Tex.—An Eastern syndicate has made a proposition to our citizens to put in an electrical railway here at a cost of $150,000 providing liberal franchises are given.

Dallas, Tex.—A franchise has been granted to L. S. Berg, C. L. Wakefield and associates to construct, maintain and operate an electric light and power plant in the city of Dallas.

Springfield, O.—A franchise for an electric railway between Springfield and Cedarville, via Clifton, has been granted to C. S. Courson and associates by the county commissioners.

Stroudsburg, Pa.—The Delaware Valley Electric Railway has passed into the hands of receivers. M. F. Coolbaugh and Edward H. Peters, of Bushkill, have been appointed.

Chelsea, Mich.—A proposition is to be submitted to a vote of the people of this village on the question of substituting arc lights for the incandescent lights at present in use here.

Nebraska City, Neb.—The stockholders of the street railway company have instructed their officers to secure estimates for an electric system, The road is now operated by animal power.

Lowell, Mass.—The Hon. John C. Burke, of the law firm of Marshall, Burke & Marshall, has recently been elected to the presidency of the Bradbury-Stone Electric Storage Company.

Dansville, N. Y.—The Dansville Electric Light Company's plant has been sold by the referee to C. H. Rowe for $8,000. The plant was sold subject to a mortgage of $10,000 held by a local bank.

Los Angeles, Cal.—E. E. Peck has filed a petition asking the council for the right to erect poles and wires for the purpose of furnishing arc and incandescent electric lights in the southwest portion of the city.

Wellsville, O.—The Citizens' Electric Light Company's plant has been purchased at receiver's sale by Homer Laughlin, of the Laughlin Pottery Company, East Liverpool, for $9,050. It was appraised at $9,900.

New York.—J. and W. Seligman, representing a syndicate of capitalists, hold an option on the stock of the Second Avenue Railroad, and if the deal is consummated the road will be changed into a cable or electric system.

Hartford, Conn.—The Hartford Light and Power Company is setting up at its works on Pearl street a new 2,000 light Westinghouse dynamo, to supply current for a large number of new lights recently contracted for.

Lexington, Ky.—The proposition to light Lexington more fully by electricity is meeting with much favor. The gas company, under the present arrangement, lights about two-thirds of the city, and the Central Electric Light Company the remainder.

Chattanooga, Tenn.—The mayor is quoted as being in favor of the city owning an electric lighting plant capable of thoroughly lighting all the streets and public places. The contract under which the city is now lighted expires in about four months.

Kingston, N. Y.—A member of the Morse Electric Economy Company of New York City has been locating the water powers in the vicinity of Rosendale with the purpose of establishing a manufactory of electrical storage batteries and switches under patents of Lansing Morse.

Reading, Pa.—The Reading and Womelsdorf Electric Railway Company has given to the Lancaster Electric Construction Company the contract to build the road from the western bank of the Schuylkill to Womelsdorf, and they are to complete it ready for operation by June 1.

Chester, Pa.—The Media, Middletown, Aston and Chester Electric Railway Company has paid Chester City $3.000, and to Chester township $1.100, and now has the right complete from Llewellyn via Village Green and Concord road to Chester city line. Operations will begin, it is said, in the spring.

Cape May, N. J.—A syndicate composed of ex-Mayor James M. E. Hildreth, ex-Collector James E. Taylor, Logan M. Bullitt and Thomas Robb, of Philadelphia, are arranging for the establishing of an incandescent electric lighting plant here. These men control the present electric light company.

Manitowoc, Wis.—The city council has directed the city attorney to prepare a bill to be presented to the Legislature empowering the city to own and operate its own electric light plant. The present plant here is owned and operated by John Schuette, whose five-year franchise expired some time ago.

Greenfield, Mass.—A temporary organization has been effected here for the purpose of getting an electric railroad built to Turner's Falls. N. S. Cutler, E. A. Hall, F. A. Pond and F. Lowe were placed upon the temporary board of directors with some Boston people, and measures will be taken to push the enterprise at once.

Clinton, Me.—A bill to incorporate the Clinton Water and Electric Company has been introduced in the Legislature. The purpose is to supply Clinton with water and electric light. The capital is not to exceed $100.000. The incorporators named are A. Rowell, S P. Felker, B. P. Porter, Geo. Leonard and W. T. Haines.

Waynesburg, Pa.—The H S. Sands Electrical Company of Wheeling has received the contract for lighting this town with 1,200 C. P. arc lights. There was very close competition between the Sands Company and the General Electric Company. The Sands Company will use Westinghouse machines.

Schoharie, N. Y.—There seems to be no doubt of the construction of an electric railway between Albany and Schoharie Court House at an early day. Local and other capitalists have been considering the scheme and are favorably impressed with the outlook. Several villages would be linked in such a line, and all would be benefited.

Milwaukee, Wis.—President James Petley of the Milwaukee and Wauwatosa Motor Railway Company says that if the council grants it a franchise to extend its line to the Northwestern depot, it will turn its entire system into an electric road, increase its capital from $200,000 to $500,000 and have the down-town line in operation by July.

Hughesville, Pa.—The Citizens' Electric Light and Power Company has been organized here and will apply for a charter. It will furnish electric light and probably power to the people of Hughesville and Picture Rocks. Among those interested in the new company are J. K. Rishel, James K. Boak, Milton Bodine, William Frontz, Peter Reeder and Howard Lyon.

Lagrange, Mich.—One of the most extensive electric plants in the State is being put in here to supply power for the Round Oak Stove Works and a commercial lighting circuit at Dowagiac. Lagrange has one of the best water powers in the State, and the electric current generated thereby will be transmitted over the intervening five miles to Dowagiac on heavy copper wires.

Springfield, Ill.—The bond given by the Standard Electrical Company of Chicago to the Capital Electric Company of this city, with the American Surety Company as security, covers the construction of the municipal light plant and guarantees it for two years. If the machines fail to give satisfaction the bond guarantees that the Standard Company will put in new machines of any manufacture the company may designate.

Binghamton, N. Y.—At a meeting of the stockholders of the Binghamton, Lestershire and Union electric road held at Union a few days ago the town commissioners signed the papers granting the company permission to construct and operate a street railway west from Lestershire through the streets of Union. It is expected that work upon the proposed road will be commenced as early in spring as the weather permits.

Brooklyn, N. Y.—The Brooklyn Electrical Society will give an "electrical smoking concert" at the hall, 315 Washington street, to-morrow (Thursday) evening, the proceeds of the entertainment to go toward the establishment of a headquarters for electrical men in this city.—The employees of the trolley roads are still on strike. Some ten or twelve of the lines are enabled to run a portion of their cars under military protection. Several regiments of militia have been guarding the stations for nine or ten days past.

Buffalo, N. Y.—The increase in the city's valuation of $50,000,000 in the last four years is attributed principally to the Niagara Falls power scheme.—Bids will be received at the Department of Public Works until February 5 for repairing and keeping in order all electric bells, pull bells, gongs, etc., at present in use in the various public schools and annexes in this city from February 1, 1895, to February 1, 1896.—The Real Estate Exchange has decided in favor of municipal distribution of the electrical energy transmitted from Niagara Falls.

Attleboro, Mass.—The Boston Safe Deposit Company, under a deed of trust, has conveyed to Edward R. Price, cashier of the Mutual Bank at North Attleboro, as trustee, all the property of the Attleboro, North Attleboro and Wrentham street railroad, the consideration being $50,000. Coupled with this is the sale by W. H. Haskell, of Pawtucket, of the North Attleboro Steam and Electric Company to the Attleboro Steam and Electric Company for 647 shares in the stock of the latter company, subject to a mortgage of $10,000. This means an immediate starting up of the electric road in this town.

Detroit, Mich.—H. A. Everett, general manager of the new Detroit Railway Company, announces that cars will be running over a portion at least of the new tracks on July 4 next. The company has contracted with the Westinghouse Electric Company for 50 motor cars, which are to be delivered at the rate of 15 cars every 30 days beginning April 11 next.—The franchise for an electrical railway line through Royal Oak township, in Oakland County, granted to the Hendrie syndicate, has been drawn up. The fare for a round trip from Royal Oak to Detroit will be 25 cents.

Worcester, Mass.—Dr. Arthur G. Webster of Clark University has received notice that he has won the Elihu Thomson international prize of 5,000 francs for the best treatise on electricity. The subject of Dr. Webster's thesis is "An Experimental Determination of the Period of Electrical Oscillations." The contest was originally instituted by the city of Paris for the best electric motor and was awarded to Prof. Elihu Thomson. With the desire that the sum should serve for the development of theoretical knowledge in electricity, he requested the general manager for Europe to offer it as a prize for the best work on a theoretical question in electricity.

Hackensack, N. J.—The National Trolley Company has filed articles of incorporation in the county clerk's office of Bergen County, N. J. The capital stock is stated to be $50,000. Ex-Assemblyman Delos Culver, of Jersey City, is the president of the company. The company will operate under the charter of the New Jersey and New York Bridge Company and will establish electric roads between Fort Lee and Englewood and the latter place and Hackensack. The Bergen County Traction Company have plans to establish trolley roads over the same route and there may be a conflict between the two companies.

Seattle, Wash.—The prospectus of the Snoqualmie Falls Electric Power Company, which proposes to transmit power from the falls to this city, has just been issued and thoroughly explains the advantages, cost and prospective revenue of the enterprise. It provides that the capital stock of the company shall be $2,000,000 in 20,000 shares of $100 each, and first mortgage bonds, $650,000, of an authorized issue of $1.000,000. The directors are Daniel H. Gilman, of Seattle; Hon. Watson C. Squire, of Seattle, United States Senator; Griffith Davis, postmaster of Seattle; Hon. Smith M. Weed, of New York, and Charles D. Wells, of Brown & Wells, of New York.

Grafton, W. Va.—Representatives of a syndicate of Baltimore capitalists have been making an investigation as to the feasibility of building a system of electric railways to connect ten of the largest towns in central West Virginia. They have gathered data concerning population, highways, traffic of existing railways, etc., and will report the plan entirely practicable. It is estimated that fifty miles of railway, built along the county roads already in existence, can reach 70,000 people and bring five county seats into communication with each other. The gentlemen who are back of the scheme are already largely interested in suburban trolley lines and want to extend their holdings.

Harrisburg, Pa.—A bill has been presented in the State Senate which provides for the establishment of a board of electrical inspectors who "shall have supervision over and the regulation of corporations supplying light, heat and power to the public; of fixing the maximum charges, and for testing the meters and measuring supply. The bill provides for one chief inspector at a salary of $4,000 per year and four assistants, one of whom shall be a practical electrician and another a chemist, at a salary of $2,000 per year each. Illuminating and fuel gas companies are included among the corporations subject to the new department." This remarkable bill has a number of other provisions, and taken altogether it would practically place every electric and gas company in the power of this board of inspectors.

Albany, N. Y.—Assemblyman Wilcox has introduced in the Legislature a bill requiring street railway companies to have the front platforms of all cars propelled by electricity or cable inclosed or screened during the months of November, December, January, February and March, except cars attached to the rear of other cars. The purpose is to shield the motormen from wind and storm while in the performance of their duty.—A bill has been introduced in the Assembly providing for the licensing of motormen and for a board of electrical commissioners in all cities of the first class in the State. The act creates a board of electrical examiners, the members of which shall receive no pay, but shall be paid their necessary expenses by the city, who shall employ an expert electrician at a cost of $10 a day, for thirty days, to conduct the examinations. Applicants for positions as motormen shall be citizens of the United States, who have resided in the State for one year and the county for three months before making application, the restrictions as to residence and citizenship not to apply to men who have been steadily employed for three months. The successful candidates for motormen are to be given licenses for which they shall pay fifty cents each. Provision is made, in case of emergency, for the board to appoint three additional expert motormen to conduct examinations, at a salary of $10 a day each. Railway companies may only employ licensed motormen where a knowledge of electricity is required, under penalty of $100 or thirty days' imprisonment.

Telephone and Telegraph.

The Orient and New York Telephone Company has begun putting up a line from Riverhead to Orient, L. I. It will extend from Orient to Riverhead, from Riverhead to Wading River, from Wading River to Oyster Bay, and then on to New York, taking in all villages on its route. The president of the company is James A. Gildersleeve, of Mattituck; secretary, John A. Bagshaw, of Riverhead; treasurer, O. B. Goldsmith, of Cutchogue.

The Telephone Company has introduced in Boston a method by which subscribers may base their contracts for service upon the amount of service desired, and pay accordingly. Small users may be charged according to the new "measured service" rates, under which the price is graded according to the amount of use, the minimum number being 500 calls per year. The price per call decreases as the number of calls increase. Every one adopting this will be supplied with the best known equipment, viz., a metallic circuit and a full long-distance outfit.

The telephone companies in Indiana towns are indulging in a rate war, and in consequence the users are being benefited. At Lafayette recently the Central Union Telephone Company cut prices from $4 per month for office and store service to $1.50, and from $3 for dwelling-houses to $1 a month. The Harrison Telephone Company has been for several months at work getting its system into operation there, and was just beginning to give the people service. They had secured a large percentage of the patrons of the old company, and the indications were that the Central Union would be without patrons. The Central Union has expended, in rebuilding and refitting its lines, adding new switchboards, etc., almost as much money as the new plant. The stockholders of the Harrison Telephone Company have decided not to make any reduction in rates to meet the cut of the Central Union Company.

The Phoenix Telephone Company of New York will put in a $11,000 plant in Dunkirk, N.Y., early in February. A representative of this company has been conferring with prominent capitalists at Jamestown, N. Y., with a view to putting in a new telephone system in that city. Jamestown has a population of 25,000.

It is reported that the Troy, N. Y., Telephone and Telegraph Company will not declare a dividend at the annual meeting, February 11th. It has been able to declare a dividend of only 2 per cent. in four years. The blizzard in 1891 damaged the lines to the extent of $70,000. The new switchboard and other improvements last year cost $30,000, and as a consequence no dividend will be paid.

Sioux City, Iowa, is getting to be quite a telephone center. Besides being headquarters for the Clark Automatic Telephone Company, the Electrical Supply Company is now making regular Bell 'phones and the Brass Works have just closed a contract for twelve automatic central telephone exchange equipments for an out of town company.

The franchise recently granted by the council of Hamilton, O., to a corporation to string wires, etc., for telephone and telegraph purposes in that city has, it is said, been sold to a newly organized company whose officers are: Jos. B. Hughes, president; F. W. Whittaker, vice president, and Thos. M. Boyd, treasurer.

The Troy *Times* has placed in its working departments the Colvin interior telephone system. The system used consists of five wall sets and a desk set, which allow communication between the editorial, counting, press, job, composing and artist's rooms.

A new telephone company in process of formation at Denver, Col., has applied for a franchise. The new concern claims to have a telephone which is just as good as the Bell and that it is now in use in many towns and cities of Iowa and Illinois. The applicants propose to incorporate for $500,000 and charge just half the rates exacted by the institution which has so long had the field to itself.

The Boston City Hospital buildings and grounds are to be equipped before long with a complete outfit for electric light and power, bells and speaking tubes, and with a telephone system of its own, which will connect all the buildings, and will consist of sixty-seven stations. There will also be a complete system of bells and speaking tubes. No official estimate can be had of the cost of this work, but it will probably range from $50,000 to $100,000.

A communication from the business men of Grand Rapids has been received by the mayor of Marshfield, Wis., asking for co operation in the establishment of a telephone line between the two places. The matter has been turned over to the Business Men's Association, and, as the proposition is heartily approved, the line will undoubtedly be built this winter. The distance is about thirty miles.

Thomas H. Epperson, a telegraph lineman, has been given a verdict in Judge Scarritt's court, Kansas City, Mo., for $4,000 against the Postal Telegraph Company. In September, 1891, Epperson was stringing wires for the Postal Company near Indianapolis, Ind. He received a shock from a live wire and fell from the cross bar to the ground, a distance of thirty feet.

It is reported that some New Yorkers are organizing a new telephone company for the District of Columbia. It is surmised that John W. Mackay is interested in the scheme.

A new telephone company at Appleton, Wis., is canvassing for subscribers. The rates are $2.50 a month for offices and $1.50 for residences. The company will start up in sixty days if 255 subscribers are obtained.

Electrician Wyman, of Boston, acting for the Central New York Telephone and Telegraph Company, is expected in a few days to begin operations in Syracuse for establishing the subway system there.

The police department of Rochester, N. Y., have made arrangements to install the Gamewell Fire Alarm Company's system in the new police building.

The Cumberland Telephone Company is preparing to run a line from Nashville, Tenn., via Culleoka to Fayetteville.

The Harrison Telephone Company, having secured a large number of subscribers in Flint, Mich., will put in a first class telephone plant in that city.

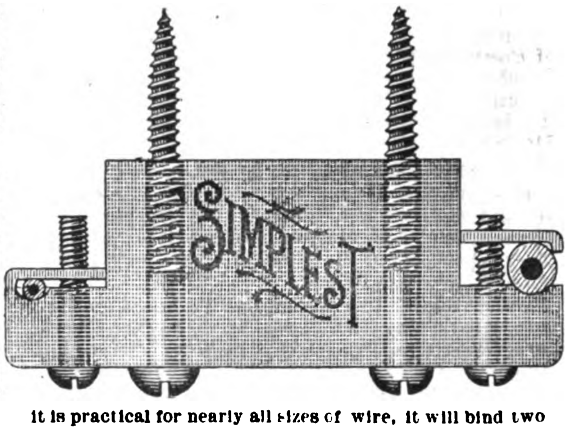
A telephone line is being erected between Magnolia, Miss., and Tylertown.

The Citizens' Mutual Telephone Company's application for a franchise is before the council at Lockport, N. Y.

The Mutual Telephone Company, a new organization, has been granted a franchise to construct and operate a telephone system in Elizabeth, N. J.

The "Simplest" Cleat.

The accompanying cut is an illustration of a new style of Porcelain Cleat recently placed on the market by the Electric Heat Alarm Company of Boston, and judging from reports the trade throughout the country is learning to appreciate its merits, numbers of good orders being daily received for it. The owners of this device explain their reason for naming it the "Simplest" by claiming that it is in one piece, it anchors the wire, it doesn't break, it doesn't cut or bend the wire, it can be put up independently of the wire, it gives perfect insulation of the wires, it is practical for nearly all sizes of wire, it will bind two different sizes of wire at the same time, and further, that it has more merit than any other cleat now in use. It goes without saying that a cleat for which so much is claimed ought to be in demand everywhere, for a first-class cleat has long been a desideratum. The electrical fraternity knows a good thing when it sees it, and doubtless the Electric Heat Alarm Company of Boston, which is already well known for other high-grade specialties, will enjoy a constantly increasing demand for what they have introduced as the "Simplest" Cleat.



The Keystone Electric Company.

The Keystone Electric Company opened the new year with prospects of the largest business they have ever had. They have just closed a $50,000 contract with the Smith-Hill Elevator Company, of Quincy, Ill., for electric motors, the contract to be completed during the year. The order is gratifying evidence of the thoroughly reliable service rendered by the Keystone motors, and is also to be taken as evidence that productive industry is on the up grade.

Notice of Removal.

The Electric Storage Battery Company, manufacturers of the well known Chloride Accumulator, announce a change in their New York offices from 45 Broadway to the Manhattan Life Insurance Building, 66 Broadway, Room 65.

It will be remembered that we announced not long since that this company had acquired all the patents and patent rights concerning the manufacture of storage batteries of the General Electric, Edison Electric Light, Thomson-Houston Electric, Brush Electric, Accumulator, Consolidated Electric Storage Battery and the General Electric Launch companies, and in this way have disposed of the legal complications which have so hampered the industry heretofore. Mr. Chas. Blizard, the New York sales agent of the company, will be found in attendance at the new quarters.

The Warren Engine-Dynamo Company, 307 Dearborn street, Chicago, has issued a handsome pamphlet containing a full illustrated description of the engine-dynamo it manufactures and calling attention to the advantages it affords in the economical and efficient production of electrical energy.

The Boudreaux Dynamo Brush Company.

The above company have established a plant in Chicago for the manufacture of the Foliated Dynamo Brush. They have all standard sizes in stock and are prepared to make special size brushes to order on short notice.

Annual Meeting of the Standard Underground Cable Company.

The Standard Underground Cable Company held its annual meeting at Pittsburg on Tuesday, January 22, 1895, and the old Board of Directors was re-elected as follows: George Westinghouse, Jr., Mark W. Watson, J. W. Dalzell, James H. Willock, John B. Jackson, George B. Hill, John Moorhead, Jr., Robert Pitcairn and Joseph W. Marsh.

The gross business for the year 1894 was $963,464, which is an excess of $101,551 over the business for the year 1893.

Out of the net profits for the year the company paid four quarterly dividends of 1½ per cent. each, or $60 000 in all. The capital stock is $1,000,000, fully paid up, with a surplus of $531,000. The company has practically no debts, except for current purchases for the months of December and January.

The prospects for the year 1895 are very good. The unfilled orders carried over from last year amounted to $58,000, in addition to which the third annual contract with the Philadelphia Traction Company for lead-covered underground feeders has just been secured, besides an annual contract with an Electric Light and Power Company for electric light cables, which two contracts give promise of at least $250,000 worth of business during the year. The Philadelphia Traction Company has bought from the Standard Underground Cable Company about $700,000 worth of feeder cables (practically underground, but also some overhead) in the last three years, and, owing to special patented devices furnished by the Cable Company, the Traction Company has an extremely satisfactory and flexible system.

In order to relieve the crowded condition of the factories the company erected during the past year a two story and basement building adjacent to its former factories, at the corner of 16th street and Allegheny Valley Railway, in the city of Pittsburg, and this building will be ready for occupancy in a few weeks. The company also expects to erect early this spring a large four story and basement building on the site of one of its present factory buildings, and when this is completed it will have an extensive and conveniently arranged plant, with sufficient capacity to keep up with any demands that may be made upon it for a good many years.

RECENT COMPANY ELECTIONS.

Edison Electric Light Company, Philadelphia. Directors: L. D. Brown, Arthur Colburn, C. A. Coffin, Samuel B. Huey, D. S. Lindsay, Amos R. Little, John Lucas, Wm. D. Marks, Chas. M. Swain, Wm. T. Tiers, H. Blake Tyler.

Market Street Consolidation Railway Company (Metropolitan branch), Easton, Pa. President, E. P. Vining; vice-president, Richard Gray. Directors: Richard Gray, C. E. Greene, W. Mills, A. N. Towne, E. P. Vining.

Card Electric Motor and Dynamo Company, Cincinnati. President and treasurer, J. W. Wilshire; vice-president, George Bullock; secretary, J.S. Neave. Directors: George Bullock, J. W. Wilshire, James W. Bullock, Capt. Geo. N. Stone, S. R. Burton, P. R. Mitchell and J. S. Neave. The only change made in the old board was the election of J. S. Neave to fill the vacancy caused by the removal to New York of Col. L. C. Weir.

Salem Electric Lighting Company, Salem Mass. President, Charles H. Price; treasurer, Henry M. Batchelder. Directors: Charles H. Price, James F. Almy, Israel P. Harris, Benjamin W. Currier, George M. Harris, C. A. Gallup, Joseph N. Peterson.

Waushara Telephone Company, Berlin, Wis. President, John Moffatt; vice-president, Mahlon Safford; secretary, Matthew Whitney; treasurer, L. E. Davis. Directors: M. Safford, J. J. Wood, Jr., Berlin; James Spencer, Auroraville; John Moffatt, Poysippi; Charles Kimball, Pine River; John P. Pederson, Mt. Morris; George P. Walker, Wautoma. C. G. Starks was appointed superintendent.

Manchester Electric Light Company, Manchester, N. H. President, Alonzo Elliott; vice-president, James A. Weston; treasurer, Walter G. Africa; clerk, J. W. Hildreth; superintendent, J. Brodie Smith. Directors: James A. Weston, Alonzo Elliott, Walter G. Africa, J. Brodie Smith, Joseph C. Moore, Harry E. Parker, John B. Varick, Frank Dowst, Joseph W. Hildreth.

Youngstown Street Railway Company, Youngstown, O. President, James Parmelee; vice-president, Silas Shook; treasurer and general manager, A. A. Anderson; secretary, John E. McVey. Directors: J. G. Butler, Jr., Silas Shook, A. A. Anderson, G. E. Herrick, James Parmelee, B. F. Miles and W. H. Lawrence.

Mahoning Valley Electric Railway Company, Niles, O. Directors: C. F. Clapp, R. G. Sykes, G. E. Herrick, B. F. Miles, Andrew Squire, A. A. Anderson and John E. McVey.

Wilkesbarre and Wyoming Valley Traction Company, Wilkesbarre. President, B. F. Meyers; general manager, John B. Graham; secretary, W. G. Eno. Directors:

B. F. Meyers, Harrisburg; J. W. Hollenback, Wilkesarre; J. J. Patterson, Lancaster; Robert McMeen, Miflin; John Graham, Wilkesbarre; Benjamin Reynolds, Wilkesbarre; Patrick Russ, Harrisburg; S. P. Light, Lebanon; W. G. Eno, Wilkesbarre.

Cleveland Electric Railway Company, Cleveland, O.—President, Horace E. Andrews; vice-president, Henry A. Everett; secretary, R. A. Harmon; treasurer, James Parmelee; general superintendent, J. J. Stanley; electrical engineer and purchasing agent, Charles W. Wason. Directors: Tom L. Johnson, Horace E. Andrews, Henry J. Davies, Henry A. Everett, R. A. Harmon, Hiram Kimball, James Parmelee, J. J. Stanley, Charles W. Wason and J. F. Whitelaw.

Cleveland Electric Illuminating Company, Cleveland, O. President, James Parmelee; vice-president, Samuel Scovil; secretary, S. C. D. Johns; general superintendent, Robert Lindsay. Directors: James Parmelee, Hubbard Cooke, Charles A. Otis, Horace E. Andrews, George Foster Peabody and Samuel Scovil.

Hartford Light and Power Company, Hartford, Conn. Directors: David Henney, W. F. Henney, E. G. Whittlesey, J. Henney, W. E. Goodwin, P. H. Quinn.

Reading and Temple Electric Railway Company, Reading, Pa. President, Benjamin F. Owen; vice-president, Matthias Moyer; secretary and reasurer, Frank G. Livingood. Directors: Matthias Meyer, W. S. McKnight, William McIlvain, Frank G. Livingood, Jonathan C. Leinbach.

Reading and Womelsdorf Electric Railway Company, Reading, Pa. President, John A. Rigg; secretary and treasurer, M. C. Aulenbach. Directors: John A. Rigg, Samuel E. Rigg, Richmond L. Jones, A. B. Hawk and M C. Aulenbach.

Metropolitan Electric Light Company, Reading Pa. President, John A. Rigg; secretary and treasurer, M. C. Aulenbach; general superintendent, Jerome L. Boyer. Dirctors: John A. Rigg, Robert N. Carson, Richmond L. Jones, Wm. R. McIlvain, R. Nelson Buckley.

Bethlehem Electric Light Company, Bethlehem, Pa. President, James Thomas; secretary and treasurer, C. A. Wolle. Directors: James Thomas and Daniel Milson, of Catasauqua; J. S. Hess, of Hellertown, and F. W. Leinbach, T. M. Dodson, Alvin Hill and C. A. Wolle, of Bethlehem.

Central Union Telephone Company, Chicago. Directors: C. H. Brownell, R. C. Clowry, C. R. Cummings, Arthur G. Fuller, F. H. Griggs, W. A. Jackson, J. Russell Jones, M. G. Kellogg, Henry B. Stone John F. Wallick and Norman Williams.

Chicago Telephone Company, Chicago. Directors: Arthur G. Fuller, John Le Koven, J. Russel Jones, John B. Drake, C. E Perkins, W. A. Jackson, Henry B. Stone, Norman Williams, Robert T. Lincoln.

At a recent meeting of the stockholders of the Franklin Electric Illuminating Company, of Sea Cliff, L. I., four new directors were added. They were Messrs. James Norton and Louis T. Duryea, of Glen Cove, and H. F. Noyes and John Tichborn, of New York City.

Schenley Park and Highlands Railway Company, Pittsburg, Pa. Directors: Richard G. Wood, president; Thos. A. Noble, F. G. Kay, S. J. Macferron, Alan D. Wood, John T. Davitt and E. M. Fulton. The Homestead and Highlands Street Railway Company elected Richard G. Wood, Messrs. Noble and Macferron and Jacob Trautman and Louis Rott as directors.

Lock Haven Electric Railway Company, Lock Haven, Pa. President, L. M. Patterson; vice-president, W. H. Mayer; general manager and secretary, R. H. Irvine; treasurer, John A. Seeley. Directors: Wilson Kistler, J. H. Fredericks, L. M. Patterson, W. H. Mayer, all of Lock Haven; C. O. Baker, Jr., J. A. Seeley and P. J. Bennett, of New York City; A. J. Belden, of Syracuse, N. Y. and Geo. Porter, of Philadelphia.

Waverly, Sayre and Athens Electric Traction Company, Waverly, N. Y. President, A. N. Broadhead, of Jamestown; vice-president, Dr. F. M. Stephens, Sayre; secretary, A. C. Wade, Jamestown; treasurer, F. K. Harris, of Athens. Directors: W. L. Watrous and W. Quigley, of Waverly; S. B. Broadhead, Jamestown; Wm. Christie and James Christie, Jr., of Akron, O., and A.C. Robertson, Athens, Pa.

Norristown and Perkiomen Creek Electric Railway, Norristown, Pa. President, Thomas H. Regan; secretary and treasurer, Paul W. Smith. Directors: Josiah Thompson, Harry E. Parsons, Jas. J. Regan.

Sanatoga, Royersford and Collegeville Electric Railway, Norristown, Pa. President, Josiah Thompson: secretary and treasurer, Paul W. Smith. Directors: John C. Lynch Clark Dillenbeck, William C. Lynch.

Philadelphia and Rosemont Railway Company, Philadelphia. President, Lincoln L. Eyre; secretary and treasurer, Arthur W. Depue. Directors: Harry Parsons, John C. Lynch and Edward H. Faulkner.

Jenkintown Electric Railway Company, Jenkintown, Pa. President, C. F. Fox. Directors: R. N. Carson, Wm. H. Shelnerdine, George S. Fox, Caleb F. Fox. D. C. Golden.

INCORPORATIONS.

The State Harrison Construction Company, Chicago. Capital stock, $100.000. Incorporators: James H. Talbot, Henry L. Talbot, William R. McLaren and John F. Talbot.

The Fulton Electric Light and Power Company, Fulton, Ill.—to operate an electric light and power plant and to furnish the citizens with electric light and power. Capital stock, $20,000. Promoters: C. C. McMahon, Ed. Wyatt, H. S. Remer.

The Wellston and Jackson Belt Railway Company, Wellston, Ohio—to construct or acquire and operate a railroad to be operated by steam, electric or other motive power. Capital stock, $500.000. Promoters: Harvey Wells, J. C. Clutts, Charles L. Currier, A. D. Lutz, F. H. Alfred.

The Jackson, Wellston and McArthur Railway Company, Wellston, Ohio—to build or acquire and operate a railroad to be operated by steam, electric, horse or other motive power. Capital stock, $$10,000. Promoters: Isaac E. Adams, Daniel J. Ryan, Edwin R. Sharpe, Chas. Kinney, Edw. B. McCarter.

The Phillips Electric Motor Company, Paterson, N. J.—to construct, establish and operate plant for supplying light, heat and power, etc. Capital stock, $100,000. Promoters: Simeon L. Phillips, New York City; Francis H. Leonard, Jr., Paterson, N. J.; Floyd B. Wilson, East Orange, N. J.

The Dravosburg and Elizabeth Electric Street Railway Company, Pittsburg, Pa.—to construct and operate a street railway. Capital stock, $40,000. Promoters: H. W. Juergen, Pittsburg, Pa.; Jno. Shrader, McKeesport, Pa.; J. R. McQuaide, Duquesne, Pa.

The Rawson Electric Company, Elyria, Ohio—to purchase, sell and manufacture telephones, electrical supplies; construct telephone lines, etc. Capital stock, $50,000. Promoters: H. C McKinley, J. B. Coffinberry, T. M. Brush.

The King Solomon Mining and Power Company, Chicago, Ill.—to develop and locate mining property; furnish light, heat and power, electric or otherwise: construct railways, tramways, etc. Capital stock, $1,000,000. Promoters: Jno. Cassleman, Arthur B. Lewis, Harry C. Igel.

The Lindner and Remig Manufacturing Company, New York—to manufacture machines wherewith to manufacture gas, electric, water, steam and other fittings and fixtures. Capital stock, $100,000. Directors: Ernst Lindner, of New York; Theo. H. Mulch, of Mount Vernon, and Philip W. Remig, of Brooklyn N. Y.

A bill to incorporate the Merrimack Valley and St. Lawrence electric road has been presented to the New Hampshire Legislature. The incorporators are Thomas Sanders, Chas. Corliss, E. B. Fuller, B. F. Sherburne and C. H. Hoyt. The road is the scheme of Chas. Corliss, of Haverhill. The road will pass through Salem, Windham, Hudson, Nashua, Litchfield, Merrimack, Londonderry, Bedford, Manchester, Hooksett, Suncook, Allentown, Pembroke, Bow, Concord, Canterbury, Boscawen, Northfield, Franklin, Sanbornton, Hill, Alexandria, Briston, New Hampton, Bridgewater, Plymouth, Ashland and other towns to the boundary line between the United States and Canada.

The Vicksburg Electric Light Company, Vicksburg, Miss. Capital stock, $125,000. Incorporators: Joseph Hirsh, Charles E. Armstrong, Murray F. Smith and others.

The Molyneux Electric Manufacturing Company, Buffalo, N. Y. Capital stock, $80,000. Directors: H. Walter Webb, Edgar Vanetten, Arthur G. Leonard, of New York City; Frank Hammond, John P. Trible, Barton S. Molyneux and Lawrence T. Hammond, of Buffalo; Frank L. Darrow and John W. Cobb, of Minneapolis.

The Mutual Automatic Telephone Company, Chicago. Capital stock, $1,000,000. Incorporators: Athol R. Mackin, Joseph Kelley and James F. Dubig.

The Natick Gas and Electric Company, Natick, Mass.—to manufacture and sell electricity for light, heat and power. Capital stock, $125.000. Promoters: Guy Wilkinson, Arthur E. Appleyard, Crayton N. Wilkinson.

The Missouri Telephone Manufacturing Company, St. Louis. Capital stock, $2,000. Incorporators; Isidor J. Kusel, Russell Parker and George J. Chapman.

The White River Water Power Company, Newark, N. J. —to develop water for commercial purposes and operate plants for furnishing light, heat and power. Capital stock, $1,500,000. Promoters: Edward Henry Brush, Brooklyn, N. Y.; Thomas A. Quillin, Hoboken, N. J.; Thos. F. Brothers, West Orange, N. J.

The Metropolitan Register Company, New York, N. Y.—to make and sell mechanical and electrical registers and indicators. Capital stock, $10,000. Promoters: J. H. Carson, New York City; J. B. Benton, Elizabeth, N. J.: J. M. Stoughton, Yonkers, N. Y.

The Westchester County Central Electrical Railway Company, White Plains, N. Y.—to build and operate a street surface railroad three miles in length in the village of White Plains and to Silver Lake Park in the town of Harrison. Capital stock, $75,000. Directors: Charles A. Johnson, Frederick H. Reed, George N. McKibbin, Charles M. Nichols, Lloyd McK. Garrison, of New York City; S. H. Gainsburg, E.C. Sniffin, and J. Henry Carpenter, of White Plains, and George W. Mansfield, of South Norwalk, Conn.

The Metropolitan Register Company, New York City—to manufacture and sell either mechanical or electrical registers or indicators. Capital stock, $10,000. Directors: John Henry Carson, New York City; John B. Benton, Elizabeth, N. J., and Joseph M. Stoughton, Yonkers, N. Y.

The E. S. Karoly Electrical Construction Company, Chicago. Capital stock, $12,000. Incorporators: E. S. Karoly, V. Merriman and J. H. Weber.

The Grand Island Light and Power Company, Grand Island, Neb.—to erect, construct, operate and maintain an electric incandescent light power, etc. Capital stock, $50 000. Promoters: H. T. Julius Fuehrman, Henry C. Joehuk, W. H. Thompson.

The Rushville Electric Light Company, Rushville, Ill.—to furnish electric light and power. Capital stock, $12,500. Promoters: C. W. Wainman, Jno. Foote, Chas. B. Griffith, J. P. Clarke, Chas. H. Wells, Jno. D. Little.

Woven Wire Brushes.

The Belknap Motor Company of Portland, Me., are the patentees and manufacturers of the best Woven Wire Brush on the market.—[*Adv.*

ELECTRICAL PATENT RECORD.

LETTERS PATENT ISSUED JANUARY 22, 1895

ELECTRIC RAILROADS AND APPLIANCES.

582,812. Trolley Wheel. Benjamin O. Paine, Millbury, Mass. Filed June 11, 1894.

582,905. Trolley Breaker. Wm. B. Potter, Schenectady, N. Y., assignor to the General Electric Company, Boston, Mass. Filed Aug. 4, 1894.

ELECTRIC LIGHTS AND APPLIANCES.

532,760. Incandescent Lamp. Mark H. Branin, Lynn, assignor to the General Electric Company, Boston, Mass. Filed April 10, 1893.

532,797. Flash-Light Device. Thomas H. Macdonald, Bridgeport, Conn. Filed April 28, 1894.

DYNAMOS, MOTORS, ETC.

582,776. Apparatus for Bending Armature Bars for Dynamo-Electric Machines. Henry Geisenhoner, Schenectady, N. Y., assignor to the Thomson-Houston Electric Company, Boston, Mass. Filed Oct. 28, 1894.

532,782. Magnetic Brush Holder. John C. Henry, Westfield, N. J. Filed Dec. 11, 1894.

582,789. Electric-Fan Motor. Joseph L. Ketcher, New York, N. Y., assignor of one-third to William L. Beadnell, same place. Filed April 26, 1894.

532,795. Armature for Dynamo-Electric Machines or Motors. Hermann Lemp, Lynn, Mass., assignor to the Thomson Electric Welding Company, of Maine. Filed March 29, 1890.

532,814. Electric Safety Device. Charles T. Penton, Christopher C. Gartland and Patrick J. Casserly, Buffalo, N. Y. Filed Feb. 2, 1894.

582,820. Machine for Assembling Laminæ of Armatures. John Riddell, Schenectady, N. Y., assignor to the Thomson-Houston Electric Company, Boston, Mass. Filed Oct. 19, 1894.

582,821. Machine for Winding Armature Coils. John Riddell Schenectady, N. Y., assignor to the Thomson-Houston Electric Company, Boston, Mass. Filed Oct. 19, 1894.

582,861 Regulator for Dynamo-Electric Machines, Louis Bell, Boston, Mass., assignor to the General Electric Company, same place. Filed Dec. 18, 1893.

532,925. Frictional Driving Gear for Bicycle-Dynamos. Ernest Tilmann, New York, N. Y., assignor of one-half to Charles K. Lexow, same place. Filed Nov. 30, 1894.

533,038. Commutator Brush. Maria R. Hirsch, Milwaukee, Wis. Filed May 31, 1894.

TELEPHONE AND TELEGRAPH APPARATUS.

532,769. Call Generator Connection. Frank B. Cook, Chicago, Ill., assignor to the American Bell Telephone Company, Boston, Mass. Filed Nov. 27, 1894.

532,979. Telephone Transmitter. William A. Mason, Sumter, S. C. Filed Oct. 26, 1894.

533,015. Telephone Switching Apparatus and Circuit. Joseph J. O'Connell, Chicago, Ill., assignor to the American Bell Telephone Company, Boston, Mass. Filed May 1, 1894.

MISCELLANEOUS.

532,790. Electrical-Display Apparatus. Joseph L. Ketcher, New York, N. Y., assignor of one-third to William L. Beadnell, same place. Filed April 26, 1894.

582,796 Electrical Conductor. Edward D. Lewis, Savona, N. Y., assignor of two-thirds to Fred S. Lewis, Lewis H. Hill, Adelbert D. Dusinberre, Horatio S. Johnson, Charles A. Van Housen, and Charles W. Gillmer, same place. Filed June 16, 1894.

532,798. Electrically-Operated Clutch. Thomas H. Macdonald, Bridgeport, Conn. Filed April 28, 1894.

582,826. Galvanic Battery. Charles B. Schoenmehl, Waterbury, Conn., assignor of one-half to Clark M. Platt, same place. Filed Nov. 14, 1893.

532,838. Electric Welding Apparatus. Elihu Thomson, Lynn, Mass., assignor to the Thomson Electric Welding Company, of Maine. Filed Aug. 13, 1889.

582,839. Electric Meter. Elihu Thomson, Swampscott, assignor to the General Electric Company, Boston, Mass. Filed Aug. 10, 1894.

532,860. Electric-Alarm Mail Box. Edward C. T. Belding, Chicago, Ill. Filed Feb. 17, 1894.

582,868. Electrical Annunciator. John S. Bull, New York, N. Y. Filed April 23, 1894.

582,909. Electric Stove. Charles E. Roehl, St. Joseph, Mo. Filed Jan. 4, 1894.

582,973. Screw-Press for Forming Insulators. Seraphin Cribs, Brooklyn, assignor to William Brookfield, New York, N. Y. Filed Sept. 6, 1894.

ELECTRICITY.

Published every Wednesday by the

ELECTRICITY NEWSPAPER CO.

B. E. GREENE, Pres't. L. J. MONTGOMERY, Sec'y.

PUBLICATION OFFICE:

6 Park Place - New York

EDITORS: NELSON W. PERRY.
BURTON E. GREENE.
R. H. WILLOUGHBY.

SUBSCRIPTION RATES:

United States, - - - - - $2.50
In Clubs of Five or More, - - - - - $2.00
Foreign Countries, - - - - - - $4.50
Single Copies, - - - - - - - 10 Cents

ADVERTISING RATES:

As Electricity reaches all classes interested in electrical work, its value as an advertising medium can be readily appreciated. Rates will be sent on application.

Changes for advertisements should reach the office not later than the Saturday preceding the date of publication.

Entered at the N. Y. Post Office as Mail Matter of the Second-Class.

N. E. L. A.—The next annual meeting of the National Electric Light Association will be held at Cleveland, O., February 19-21, 1895. Every concern interested in either lighting or railway work should be represented in the membership of this body, and should have at least one representative at the Cleveland meeting. The Secretary is Mr. Geo. F. Porter, 136 Liberty street, New York.

EDITORIAL NOTES.

Modern Theories as to Electricity. In our issue for January 9 we reprinted from the *Engineering Magazine* Prof. Henry A. Rowland's article on "Modern Theories as to Electricity," and editorially commented upon it, calling attention to some of the radical differences between his opinions and those held by Prof. Oliver Lodge as expressed in his work, "Modern Views of Electricity." We also questioned the sufficiency of the "Vortex Theory of Magnetism," as held by Kelvin, Maxwell and others, and asked for more light on this perplexing question. In our ignorance of the subject, it seemed to us that the observed facts controverted the idea that magnetism could in any way be a kinetic phenomenon as the vortex theory would seem to imply. It seemed to us that if it were kinetic, then the presence of a magnetic substance in a magnetic field should constitute a drag upon that energy which would require a constant supply of energy from without to maintain it at undiminished strength. This retarding effect on the vortex would be entirely separate and apart from that which might be attributable to molecular friction or to hysteresis, and would, it seems to us, have to be provided for in any kinetic theory of magnetism. As a matter of fact, however, in a permanent magnet, be it either of highly tempered steel or of the softest iron, the magnetism seems to remain unimpaired in strength as long as work is not done on the metal to discharge it. We are speaking now of magnetism as evinced in ferric substances. In non-ferric substances such as air, the phenomenon would seem to be clearly kinetic, requiring a constant expenditure of energy to maintain it even in air, but a still greater expenditure in the presence of magnetic substances which act as a drag on the supposed vortex. Thus in the phenomena of heat which is generally believed to be kinetic and due to molecular vibrations, we find all other cooler substances acting as a drag upon these vibrations until they and the originally hotter body have both been brought to the same temperature. According to Kelvin's theory of matter, the atoms are themselves nothing but vortex rings of the ether. It postulates a frictionless medium, else these vortices would themselves die out, and we would have the phenomenon, which is contrary to experience, of the destructibility of matter. But however difficult it may be for us to accept this theory of matter, and it seems thus far to be the most tenable of any yet presented, let us assume that matter has this construction—and there is no difficulty in the assumption—still we are met by the fact that *one* kind of vibration of this vortex matter, such as heat, is capable of retardation, and so are all forms of radiant energy when impinging upon matter. How then can magnetism, if a phenomenon of the same order, be explained? It is not enough to advance the theory of molecular magnets any more than it is enough to advance the theory of molecular vibrations as the source of sensible heat—the question still remains, what *maintains* those conditions and how do they in the case of the molecular magnet produce the observed phenomena? A theory that magnetism is entirely static would seem to fill the requirements more fully, and while the explanation would not be ultimate any more than are the current explanations of electrostatic attractions and repulsions, it would bring the two into the same *order* of phenomena, and do less violence to our accepted theory of the conservation of energy than the vortex theory does, *as we understand it.*

In the issue before referred to, we expressed our misgivings with considerable diffidence, assuming that they were due entirely, or at least largely, to the insufficiency of our grasp of the theory rather than to the insufficiency of the vortex theory itself. We had hoped for our own benefit, as well as for that of many of our readers, that Prof. Rowland would clear up the difficulty for us—at least in part—and we addressed him a personal letter on this subject, but as we go to press have heard nothing from him.

It seems, however, that we are not alone in our perplexity, for during the past two or three weeks we have received a number of communications from men who stand high in electrics who are in the same mental darkness on this point as ourselves.

In this issue, we reprint from the London *Electrician* of January 18 a communication from Dr. Oliver Lodge himself, who in reviewing Prof. Rowland's Paper raises very much the same questions that we did in our review of January 9th. In regard to Prof. Rowland's theory of the earth's magnetism, which is but a corollary of the general vortex theory, Dr. Lodge quotes the author thus :

"To account for the earth's magnetism, we must suppose the ether to have such properties that the revolution of ordinary matter in it produces magnetism." . . . "The ether must also account for the earth's magnetism. If we assume that magnetic lines of force are simple vortex filaments in the ether, we have only to suppose that the ether is carried around by the rotation of the earth, and we have the explanation needed. The magnetism of the earth would then be simply a whirlpool in the ether."

Upon this he makes the following comment :

"Now these statements are full *of more than doubtful hypotheses.* [Italics ours.—ED.] First, that magnetism is certainly due to rotation of something, which, although Thomsonian and Maxwellian, *has never been proved ;* next, that rotating ether is the necessary and sufficient whirling material, whereas all that is known is that rotating electrification is sufficient; and lastly, that the spinning of matter on its axis, magnetizes it, against which may be adduced a crowd of specially-directed experiments, all of them *having had a negative result.*"

And further along he says, in speaking of Prof. Rowland's adhesion to the vortex theory of magnetism : "It may be assumed as probable that he had strong reasons for this orthodox Maxwellian belief, and it would be interesting to know them."

This, it will be observed, is exactly the position which we assumed a month ago.

While it is too much to expect at this time an ultimate theory of magnetism that will be acceptable to all, it is only by discussions such as Prof. Rowland's Paper has called forth, and is likely to call forth, that we can hope to approach more closely to the desired end.

Personally, we had hoped to see these great questions, What is electricity ? What is magnetism ? What is the ether ? brought up before the Electrical Congress at Chicago. We believed that although no definite answer could be expected in the present state of our knowledge, still an open discussion would have resulted in a more definite understanding of where science stands to-day on this vital question; that even though no ultimate and satisfactory statement could have been made, it would have given us a new datum from which to build *toward* that which *would* be more satisfactory. That opportunity has passed by, but another one will be presented at the Paris Exposition, and it is to be hoped that preparation for the final discussion may be made by a free interchange of thought through the electrical press during the intervening time.

* * *

The Hopeless Case of General Electric. The friends of General Electric, or rather those who are still making apologies for that rotten concern, tried to excuse away the slump to 29⅝, which its stock took a week ago, on the ground that it was in anticipation of an unfavorable decision in the Bate Refrigerator case. A purchase of some 2,500 shares at a very low figure by Boston parties sent the price up a point or two, but it could not hold at this and has been below 29 part of the past week. At one time it touched 28½, and is going still lower before long. Monday has come again and, as predicted in these columns last week, there is still no decision in the Bate case, and this must go over now until after the February recess. The sales in General Electric during the past week exceeded those of every other stock except American Sugar, being a very good second, however—102,900 for the former as against 126,979 for the latter. In point of decline, however, General Electric refuses to take second place to any other stock. Its only competitors in the downward scale among the more active stocks were L. and N. with a decline of ⅜, Distillers ⅝ and Southern Ry. pref. ¼. General Electric made a net loss of 3⅜ or nearly three times as much as the combined slump of the other three.

The apologists for G. E.—apologists for revenue only, for there is no apology for the existence of this fraud—attempt to account for this showing by the general disturbance of the money market and the uncertainty in regard to a new bond issue. But why should G. E. decline 3⅜ while nearly every other stock of importance on the list advanced ?

There are two very plausible excuses for this slump, which is larger relatively than it is intrinsically, viz., the gradual approach of the annual statement, which must either be falsified or else show the utter worthlessness of the stock or the too evident desire of the Board of Directors to get under cover before the crash comes, as evinced in the extraordinary resolutions which they passed and which we published in the last issue.

Anything more inane or transparent than these resolutions would be difficult to conceive of and the public was not slow in catching on. But desperate cases require desperate measures, and when the penitentiary stares a criminal in the face there is no straw too small for him to clutch at in his vain endeavor to escape the just penalty of his crimes.

Consumption is regarded as a surely fatal disease. Its course is marked by spurts of apparent improvement followed by relapses, each one of which is worse than the preceding. Down, down, and further down the patient sinks until death relieves him of his mortal cares. Is not this a correct diagnosis of G. E.?

Under the Searchlight.

Views and Opinions on Timely Topics.

HAS MR. TWOMBLY GOT ENOUGH ?

It was stated last week in several of the daily papers that Mr. H. McK. Twombly had unloaded a large part of his G. E. holdings, and that this caused the conspicuous weakness of the stock.

Of all the legs in the G. E. Company, those of Mr. Twombly have been the longest and most elastic. It has been said by those who ought to know that he lost over $1,000,000 on the decline. If at last he can see the actual situation of the company, he may save a part of his large fortune.

* * *

Oh, Musha! Musha!

Our esteemed contemporary, the *Electrical Review*, in its last issue mentions by name some of those that ELECTRICITY in a previous issue referred to as having too much self-respect to continue patronizing a sheet that descends to Baxter street methods. We quote verbatim :

> "Four well-known houses—the Armington & Sims Engine Company, the McIntosh & Seymour Engine Company, the Okonite Company, Limited, and the Law Battery Company—have discontinued their advertisements in the *Electrical World*. The impertinent circulars issued from that office did it. The proprietor, W. J. Johnston, with a record of three failures in the past, with a sawdust periodical in the present and a challenge ringing in his ears to produce a few paying subscribers, sends out a pathetic card headed :
>
> "'Tis the wounded bird that flutters.'
>
> "Poor flutterer !"

Other people better fortified in every way than Pudd'nhead Johnston have found that "the public be damned policy" didn't work. Mr.—no, beg pardon—Pudd'nhead Johnston is likely to learn that when a man goes around town with his coat tails trailing on the ground, crying "There's not a gossoon in the village dare tread on the tail o' me coat," it is very likely to be trodden on in time to interrupt the refrain, "and mush, mush, mush toori a laddie, and a mush, mush, mush toori a lay" all the eggs in one basket.

* * *

A generally well-informed Jersey City paper states that the General Electric Company intends to remove the Harrison, N. J., branch of its lamp department to Lynn, Mass. ELECTRICITY predicted some months ago that the establishment at Harrison would soon be closed. This adds another to our predictions concerning G. E. that have been fulfilled. The writing at Belshazzar's feast was not plainer to Daniel than the drift of G. E.'s concerns to ELECTRICITY.

* * *

MR. A. J. DE CAMP will be looking after his probable election to the Philadelphia City Council during Convention week, and will be one of the old-timers missed at the Cleveland meeting.

* * *

IT certainly was not a daily paper attack that played the mischief with G. E. last week.

American Institute of Electrical Engineers.

POSTPONEMENT OF FEBRUARY MEETING.

We are informed by Mr. R. W. Pope, secretary, that on account of dates conflicting with the Convention of the National Electric Light Association at Cleveland February 19, 20 and 21, the regular monthly meetings of the Institute at New York and Chicago have been postponed from February 20 to Wednesday, February 27, 1895.

The paper to be presented on the latter date is by Mr. H. Ward Leonard, entitled "Notes on

Recent Electrical Engineering Development in France and England," being the results of the author's personal observation in electric light, railway, central station and underground practice.

The usual notices will be mailed in advance of the meeting.

National Electric Light Association Convention.

The following have been added to the papers and topics heretofore furnished for the Cleveland programme:

Paper: "A New Method of Measuring Illumination," by Professors E. J. Houston and A. E. Kennelly.

Topic: "Underwriters' Rules vs. National Electric Light Association Rules."

Topic: "Practical Demonstration of Protecting Lines from Lightning," by A. J. Wurtz.

The entire programme for the Cleveland Convention is now completed and only awaits the approval of the president. It will doubtless appear in the next issue of this paper.

In the interests of those who wish to attend the N. E. L. A. Convention, arrangements have been completed with the New York Central and Hudson River Railroad Company for a special train of the Wagner vestibule, parlor, dining room and buffet cars, leaving Grand Central Depot, 42d street, New York, at 9:30 A. M. Monday, February 18, running as second section of the fast mail on the following schedule: Leaving New York 9:30 A. M.; Albany 1 P. M; Utica 3:17 P. M.; Syracuse 4:40 P. M.; Rochester 6:30 P. M.; Buffalo 7:25 P. M. (Central time); Erie 9:33 P. M. (Central time); arriving at Cleveland 11:55 P. M.

Seats can now be secured on this train by applying in person or by letter to the office of the National Electric Light Association, 136 Liberty street, New York.

A special rate has been granted (on certificate plan) of a fare and one-third from all points in the United States east of the Mississippi River, Peoria and Chicago, Ill., to Cleveland. To obtain this rate it is necessary in purchasing going ticket to ask the ticket agent for a certificate, which, when properly viséed and indorsed at Cleveland, will entitle the purchaser to a one-third fare returning.

That the best results may be obtained it is very desirable that delegates should make their application for space on the New York special at the earliest possible moment.

The following gentlemen have charge of transportation in their respective districts, and application can be made to them for all information:

A. C. Shaw, 620 Atlantic avenue, Boston.

H. A. Cleverly, 1018 Chestnut street, Philadelphia.

E. H. Heinrichs, Westinghouse Electric Company, Pittsburg.

E. L. Powers, Monadnock Building, Chicago.

The Brooklyn Electrical Society's "Smoker."

The electrical smoking concert of the above society, on Thursday night last, was a very pleasant affair, and though begun in smoke and carried through amid the fumes from corn-cob pipes, cigars, cigarettes and congeneric stock, yielded substantial enjoyment to about two hundred of the brightest young men in the city.

President Burling opened the proceedings with a few remarks, and was followed by Arthur A. Fisk, chairman of the Entertainment Committee, who in a humorous speech welcomed the crowd to all the amusement they could obtain from what the committee had provided for their benefit.

Under the direction of James H. Mason, "Funny Things from the Phonograph" were given. Then came "The Sheehan Boys," John T. and Dan, and their comic songs and parodies, which were repeatedly encored. Others who entertained the audience during the evening were Thomas A. Ballantyne, the humorist; George J. Gaskin, the Brothers Murray, May Alpine and Harry W. Wright, of Harrigan's, who sang selections from McSorley's Inflation." A vote of thanks was given to the talent, whose services were given gratis, and "A Night Cap for All" concluded what was pronounced by every participant "A night well spent."

The "smoker" was given as one of a series of entertainments to raise funds to open club rooms where members of the society can meet in social as well as educational intercourse, and to make such rooms a headquarters for electrical men in Brooklyn.

Explosion at Brinton.

On Saturday last a laborer at the Brinton Works of the Westinghouse Company held a lighted match in the bunghole of an old barrel to see what was in it. It had contained alcohol, and enough was left to make a terrific explosion. The man was killed and two others seriously injured.

Obituary.

The electrical fraternity will be shocked to learn of the death at Washington, D. C., on January 23 of Mr. Rudolph Eickemeyer, whose name is so well known in connection with numerous important inventions relating to the electrical industry. While Mr. Eickemeyer's health had for a long time been impaired—he was a great sufferer from asthma—his friends had at no time been alarmed at his condition, but in the hope of finding relief he was on his way to the South. He had stopped over at Washington for a few days on a matter of business connected with the Patent Office when his trouble took on a serious turn and the end came as announced.

Mr. Eickemeyer was a Bavarian by birth, but came to this country in 1850, settling in Yonkers, N. Y., where he established a tool repairing shop. The faculty of invention was strongly developed in his nature and he soon found both fame and fortune in the exercise of this faculty. Among his earlier inventions were improvements in the manufacture of hats. A machine for making leather hat bands, now widely used; a sewing machine for sewing these same bands into the hats, and hat blocking machines and bouncers were the chief of these, from which he received large royalties.

With the advent of electrical development he turned to this as an inviting field, and the Eickemeyer method of winding for motors and dynamos was received with great favor. In connection with Stephen D. Field he developed many improvements in electric car equipments, one of which, following steam locomotive practice, consisted in driving both axles from the same motor by connecting the two drivers by means of parallel motion connecting rods. He was an indefatigable worker and his inventions in the electrical line alone are too numerous to mention in this connection. Some of them were of extreme originality and have failed as yet to meet with favor, but others have possessed such unquestioned merit as to stamp him as an inventor of an original and high order. A widow and six children survive him.

Two novel applications of the electric heater have been made in London. One is a wheat dryer in the form of a wooden box containing nineteen electrically-heated plates, which are maintained at about 200 degrees F. Air is forced over these plates by a blower, coming out at about 150 degrees F. The second novelty consists in applying electrically-heated plates to the top and sides of the case of steeple clocks, by which the accumulation of snow and ice on the face is prevented, and the movements of the hands are protected from the interference which would take place from this cause.

London Notes.

(From our London Correspondent.)

THE CHLORIDE BATTERY LITIGATION.

I am pleased to be able to state that the disputes which were likely to lead to lengthy and expensive litigation between the Electrical Power Storage Company, Chloride Electrical Storage Battery Company, Limited, and the Electrical Construction Company, Limited, have been settled on mutually satisfactory terms. Under the agreement which has been arrived at the Chloride Company continue to make and sell their batteries as heretofore.

THE ARC LIGHT.

Prof. Silvanus P. Thompson delivered the second of his Cantor lectures on "The Arc Light" on Monday, January 21, before the Society of Arts. He dealt more particularly on this occasion with the optics of the electric arc. Most of the total light, he said, is given off from the crater, less than 10 per cent. coming from the peak. The crater may be regarded as a flat, self-luminous area. If it could be seen in such a way that the peak never came between it and the eye it would give the greatest light when looked at perpendicularly and the least when the line of vision was parallel with its surface. But the shadow of the peak has to be reckoned with, and it is found that the light given off is directly proportional to the area of crater actually exposed to view, being greatest at an angle of 40° or 50°. In the middle of the crater there may sometimes be discovered with the unaided eye a nebulous patch, rather whiter than the rest, which seems to be in motion. By the use of appropriate artificial means this patch may be seen as a comma-shaped object, which rotates around the crater at very varying speeds and not always in the same direction. It is a question whether this is a true physical rotation of the flame or only an optical effect. As to the efficiency of the arc regarded as a means of transforming energy into light, the lecturer said that of all the rays given off by it only 20 or 25 per cent. are visible to the eye, the rest of the energy consumed is transformed into heat. The light from an alternate current arc is more equally distributed than that from a continuous current arc. As to the comparative efficiency of alternate and continuous arc lights, he thought it wrong to suppose there would be any difference between the two if the same amount of energy were consumed under equal conditions.

LECTURE BY PROF. DEWAR.

At the Royal Institution on Friday, 18th ult., Prof. Dewar, F. R. S., delivered a discourse on "Phosphorescence and Photographic Action at the Temperature of Boiling Liquid Air." The lecturer showed a number of experiments proving that bodies which at ordinary temperatures are very faintly, if at all, phosphorescent, glow very brightly if, after being cooled to the temperature of boiling liquid air they are stimulated in the light of an electric lamp. Among the substances he experimented upon were cotton-wool, feathers, flowers, egg-shells, quinine, acetic acid, and some of the complex platino-cyanides, the latter giving very brilliant effects. He proved experimentally that the stimulating power of the electric lamp lies chiefly, if not altogether, in its ultra-violet rays, and he showed the curious fact that the luminous and heat rays are able to dissipate the luminosity of a phosphorescing body in those parts upon which they have fallen.

The New Westinghouse Works.

The new factories of the Westinghouse Company at Brinton are assuming a business-like aspect. Manufacturing is being done already on a large scale, and one day last week over 100 motors were loaded and shipped.

Popular Electrical Science.

X.

The Microphone or Battery Telephone Transmitter—The Footfalls of a Fly Made Audible to Human Ears—The Great Service Rendered to Science by this Simple Invention.

BY NELSON W. PERRY, E.M.

I have pointed out that the principle underlying telephonic transmisson was an electric current varying in strength in exact harmony with the sound waves which are to be reproduced. In the magneto instrument described in Chapter IX the vibration of an iron diaphragm before a magnet carrying a coil of insulated wire was used to generate this current. The same results can be produced more efficiently, however, if we generate a steady current in a battery and then cause this to vary in strength by adding to and taking away from the line some of its resistance. Prof. Hughes in trying some experiments to find a method of readily varying the resistance of an electrical circuit, filled a glass tube of about 3 inches in length with bronze powder. The ends of this tube he closed by means of dense gas retort carbon plugs, so that the metal powder was pressed gently together. The wires fastened to the carbon plugs formed a closed circuit with a battery and a galvanometer. So long as the tube was untouched the galvanometer needle remained stationary—indicating the passage of a perfectly steady and unvarying current. But when grasping the two ends of the tube in his hands he exerted a pressure or pull, the needle showed a deflection either in one direction or the other. This could only be attributed to an infinitesimal elongation or compression of the tube, due to the manual force applied. Placing this same tube upon a resonance box and inserting a telephone receiver in the circuit, he found that words spoken into the resonance box could be distinctly heard in the telephone. In other words, the sound vibrations imparted to the resonance box had modified the resistance of his tube in such a way that the current which was passing through it was modified in like manner, and this undulatory current was translated back into sound waves by the telephone which corresponded in every particular except volume with those which originally gave rise to them. Prof. Hughes had invented the microphone. After the principle that a very slight variation in the pressure between contact surfaces was sufficient to vary an electric current within the limits of delicacy of the telephone to detect was discovered, and that sufficient variation in pressure could easily be produced by sound waves, a thousand different forms of microphones sprang into existence, and in fact that which had previous to Prof. Hughes's discovery been regarded as so impossible of attainment as to make it seem almost a waste of time to experiment on proved afterward to be the simplest thing in the world. Prof. Hughes himself showed that three wire nails, arranged as in Fig. 1 so that the current passed from one to another by means of a third lying across the two, if placed on a sounding board were an efficient microphone. It seems, too, that we cannot throw a mass of metallic rubbish together even in the most careless and haphazard manner but that it will, if connected in an electric circuit with a telephone, transmit articulate speech if spoken to. It required no new device after the principle was discovered to make that principle operative. The Morse telegraph sounder if adjusted to very light touch is itself an excellent telephone transmitter, and so would have been Reis's transmitter, described some weeks ago, had not the pressure of the contacts been purposely made so light that at every vibration of the diaphragm the contact became broken. In Reis's time, however, there was no instrument delicate enough to detect these slight variations in current. Had there been, it seems extremely probable that to him rather than to Hughes would the discovery of the microphone been accredited. It remained, however, for the telephone to make the recognition of these slight variations possible, and the microphone has in turn contributed much to the efficiency of the telephone—especially where long distances are involved and where volume of sound is essential.

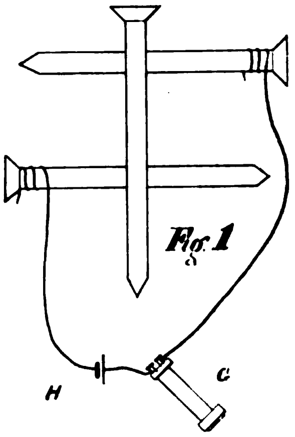

Fig 1

The microphone, therefore, is simply a contact between two conducting substances, the resistance of which is caused to vary by the sound waves which agitate them. If the vibrating parts be very light, the instrument will be very delicate and respond to sounds entirely inaudible to the human ear. If on the other hand they be heavy, or they be held against each other with some pressure, they will respond only to the louder sounds. If the instrument is so delicate as to break contact from the vibrations to which it is exposed, it cannot be used to transmit those sounds, but in many cases it is desirable to make the instrument as delicate as possible. For this purpose the moving contacts are placed upon a sensitive sounding board, so as to magnify the disturbance as much as possible. Where extreme delicacy is required, nothing better in the way of a sounding board can be devised than a thin pine board, and the thinner the better.

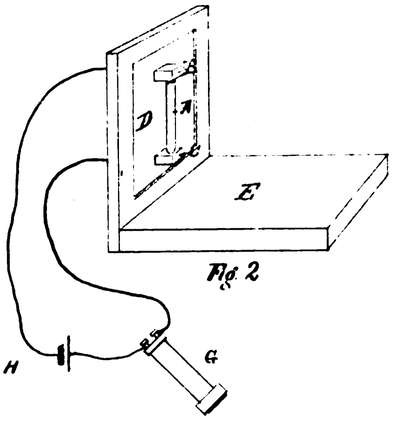

Fig 2

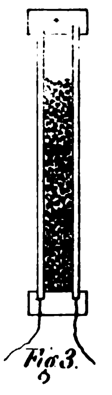

Fig 3

Now as to the material of the contact pieces. While the broad statement that anything that will conduct electricity may be used is entirely true, there is still a great choice, and of all known materials carbon is found to be best. If two small carbon rods be glued to a pine board and a third rested lightly upon these two, and the whole connected up with a battery and telephone as in Fig. 1, a microphone of extreme delicacy will have been constructed. If all the parts be very light, such an instrument will be too delicate for the transmission of speech, simply because the vibrations of the board due to the voice will cause the riding piece to hop and break contact. If this should be found to occur, it is only necessary to replace the light riding piece with a heavier one.

Another and more convenient, and still very delicate, microphone is illustrated in Fig. 2. *E* is a square pine block carefully planed, and varnished if desired. Its dimensions may be 3 inches or 4 inches square and ½ to ¾ inch thick. Nailed to the back of this is a light pine wood frame upon the back of which is glued a pine board *D*, about ⅛ inch thick. Attached to the face of this are two carbon blocks about ½ inch square and ¼ inch thick. These are represented by *B* and *C*. Between these two blocks is placed a light carbon pencil *A*, tapered at both ends and fitting *loosely* into conical recesses cut into *B* and *C*. These latter blocks are then connected in circuit with a galvanic cell *H* and a telephone *G* as shown.

If the parts be made of the dimensions given, this instrument will be too delicate for the transmission of any sounds louder than the softer whispers, but a watch placed on the base *E* will sound something like a trip hammer over a circuit hundreds of miles in length, and the soft musical ring of the mainspring, which perhaps few have ever heard before, will be plainly audible. It is said that the tread of a fly may be distinctly heard under such conditions, and I see no reason why that should not be true if the parts of the apparatus be made light enough and other sounds entirely excluded.

Another type of microphone, known as the "Hunning," is shown in Fig. 3. This consists simply of two thin metal diaphragms set up in a wooden or other non-conducting frame, with the space between the two diaphragms filed in with finely granulated carbon or graphite. These granules are usually about the size of a small pin head. The electric current is caused to pass from one diaphragm to the other *through* the granulated carbon, which normally has a high resistance. So long as the two diaphragms remain perfectly still this resistance remains perfectly constant, but if one of the diaphragms be spoken to it will be set in vibration by the sound waves, and this vibration will alternately bring the carbon particles into greater and less intimate contact with each other, thus varying the resistance and the strength of current that will flow. This type of microphone has some marked advantages for transmitting conversation. In the first place it is exceedingly delicate, and will readily transmit whispers, while at the same time it will transmit the loudest noises without danger of breaking the circuit, which I have pointed out would be fatal to the transmission of speech. It has great range. It has the disadvantage, however, when constructed as shown, of becoming less and less serviceable with use. This is due to the eventual *packing* of the carbon particles. When this occurs, however, it may be brought back to its original sensitiveness by simply inverting it, or shaking it a little so as to loosen the pack. A very large variety of telephone transmitters are made on this principle.

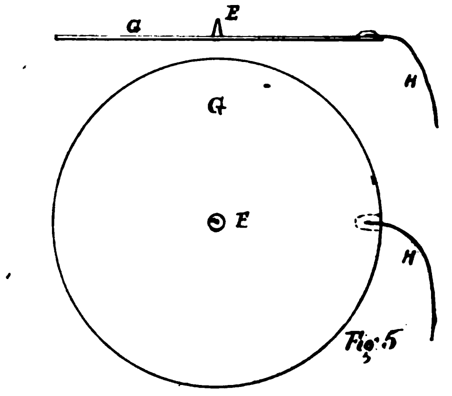

Fig 5

Among the best known of these are the long distance transmitters used on the American Bell Telephone lines between Boston and New York and Chicago. In these the packing tendency is entirely overcome.

Still another type of microphones is that represented by the Blake transmitter, which has heretofore been used almost exclusively by the telephone companies throughout the United States. This is an adjustable microphone, which for a given adjustment has a somewhat limited range, but which is capable of any adjustment desirable, so as to adapt it to the service required. The instrument as installed by the American Bell Telephone Company looks somewhat more complicated than it really is, but could not be reproduced by the amateur unless he had more facilities for manufacture than he usually possesses. I will describe one, however, that I have frequently constructed for myself out of ordinary materials at home, and which works admirably in every respect.

In the first place, take a square block of wood about 4 inches square and an inch thick. In the center of this bore a hole half an inch in diameter clear through, and then cut away on one side a conical or bell-shaped area to concentrate the sound waves. This is shown in section in Fig. 4. Cut out a circular disk of ferrotype plate about 2½ inches in diameter, and after having scraped off the enamel in the center, solder on a metal point, as shown at *E* in section and plan in Fig.5. To the edge of the disk also solder the end of a fine insulated copper wire—having, of course, previously cleaned the disk at that point for this purpose. Then buy at the drug store about 8 inches of soft rubber tubing ⅛ inch or less in external diameter, and slitting it longitudinally along one side, stretch it somewhat tightly around the circumference of the disc just as you would apply a braid to the edges of a piece of cloth, and sew the two ends together so as to keep the rubber in place. The wire *H*, Figs. 4, 5, 7, may be brought out through a little hole punched in the tubing for that purpose, or, better, at the point where the two ends of the tube come together. The object of this rubber braid is, first, to dampen the vibrations at the circumference of the diaphragm, and, second, to form an elastic cushion for the diaphragm when it is placed in position on the block. This diaphragm is then placed centrally on the reverse of the block, as shown in Figs. 4, 6 and 7, in which similar parts are lettered alike. *E* is the point or boss. *O* is the rubber tube.

To hold the diaphragm in position, mount a short piece of heavy clock-spring *M* on the block. Cover the end of this which is to bear on the diaphragm with a short length of rubber tubing, and then screw it down sufficiently so that it will hold the diaphragm fairly tight in place. It would be better if this finger was made of something considerably stiffer than a clock-spring, as its pressure must be firm. All the elasticity required will be given by the rubber cushion on its bearing surface.

We must now have a carbon anvil, whose pressure against the contact point *E* can be regulated at will. This can be conveniently made as follows: Procure an empty pistol cartridge shell and cut it off to about half its length (*A*, Fig. 8). Cut off a piece of clock spring about 2¼ inches long *B*, and solder one end of it to the back of the cartridge. This will make a holder for the carbon button attached to a flexible arm. Drive into the bottom of the cup *A* about ¼ inch of lead in order to give it inertia, and then force into it a carbon button *C*. Draw over the arm *B* a section of soft rubber tubing, shown at *P* in Figs. 4 and 7, and mount the whole on the block, as shown in the same figures, in such a way that of its own weight the carbon button *C* will not come in contact with the point *E*. This may be accomplished even after the spring is mounted by bending back the spring so that it will acquire a sufficient set to hold the button away. Then construct on the block a light wooden bridge *Q*, Figs. 4, 6 and 7, spanning the diaphragm and the spring, and in the center of this bridge insert an ordinary wood screw *L*, so that when screwed down it will press on the rubber covered spring about ⅓ the distance between the anvil and the other end of the spring. Fig. 6 shows a section of this bridge and screw, Fig. 7 a plan of the completed microphone, and Fig. 4 an elevation of the microphone on a plane passing through the spring, anvil, contact point and finger *M*.

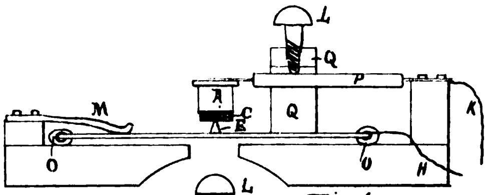

Fig. 4

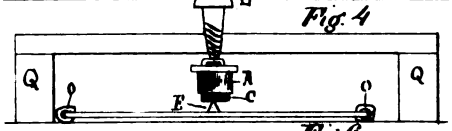

Fig. 6

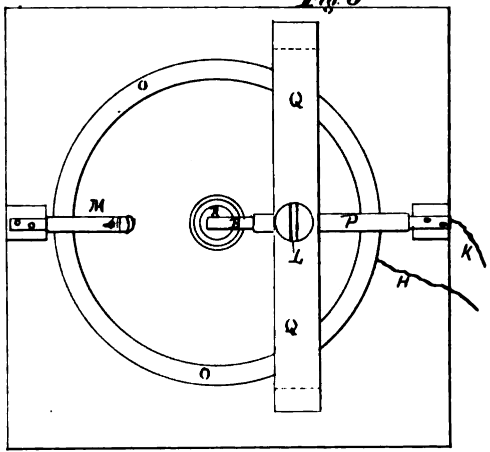

Fig 7

By screwing in or out the screw *L* the normal pressure of the carbon button *C* upon the point *E* may be made anything desired, so that the transmitter may be readily adjusted either to whispers or loud shouts. By attaching a copper wire *K* to the end of the spring the microphone may be easily connected in circuit with a battery and telephone. The course of the current will be through the wire *K*, spring, anvil *A*, carbon button *C*, contact point *E*, diaphragm, and wire *H*, or in the reverse direction.

The object of placing the rubber tubing on the spring is to dampen any vibrations that might be set up in it by the diaphragm when in use, and the object in adding lead to the cup is, as before stated, to give this sufficient inertia, without which the action would be less satisfactory.

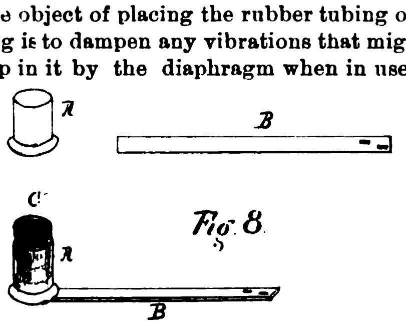

Fig. 8

This particular feature of the instrument is of historical interest. During the celebrated Drawbaugh litigation, in which the endeavor was made to show anticipation by Drawbaugh of the telephone invention and its various adjuncts, a microphone of the Blake type, purporting to have been made and used prior to the issue of Blake's patent, was brought in evidence. The Bell people met this by the claim that the instrument in question was merely a copy, and that in copying from Blake he had omitted the soul of the invention. viz., giving the anvil inertia by weighting it. The Blake patent has now expired, so that instruments such as the ones described may be made by anyone without liability or danger of infringing.

In the next chapter I expect to describe the methods of connecting up the transmitters, receivers and call-bells for service such as is required on private lines.

The Best Metal for Field Magnet Frames.*

BY ALTON D. ADAMS.

Cast-iron, cast-steel and wrought-iron being the materials at our command for field magnet construction, it is an important question to the engineer and manufacturer which will produce a dynamo of given capacity, speed, efficiency and working qualities at the least cost.

I am not aware that any of the works on dynamo construction attempt a definite answer to this question, and the practice of builders is by no means uniform. Economical points of saturation requiring about the same magnetizing force per unit of length in each metal, are for cast iron a little under 40,000, cast-steel, 70,000 to 80,000, and wrought iron about 90,000 lines per square inch.

The cost of cast-steel is fully equal to that of forgings in simple shapes, and as it lies between cast and wrought iron in magnetic qualities, the cost of machines made with it will be between those of cast and wrought iron. A comparison will therefore be made between the cost of the latter two.

To be fairly compared, machines of different materials must be equal as to magnetic flux in field and armature cores, ampere-turns on armatures, field ampere-turns required in air-gaps and as nearly as possible in magnet frames, watts used in windings, and be of the same capacities and speeds.

Taking wrought-iron at a saturation of 90,000 and cast at 40,000 lines per square inch, the section of an equivalent cast will be two and one-quarter times that of a wrought frame, and as the length of the cast-iron frame must be a little greater to give enough winding length, its weight will be about two and one-half times the wrought. A saving is thus at once made in favor of the wrought magnet, as forgings can be had per pound for much less than two and one-half times the cost of cast-iron.

The same number of ampere-turns and watts being required for the coils of the cast as the wrought-iron magnet, and the weight of wire varying as the square of its length, the coils for the cast-iron frame will be much heavier. The armature core may have the same diameter in each frame, but must be longer in the cast frame so as to come under the pole-pieces, thus materially increasing its weight.

As for the same resistance the weight of armature winding increases as the square of its length considerable more wire is required for the armature core of the cast-iron machine. In addition, the purely mechanical parts, shaft and base, must be larger and more costly in the cast-iron machine because of the greater weights they have to carry.

To illustrate the difference in cost of construction, the following data of two machines is presented, each having capacity of 25 K. W. of 1,275 revolutions per minute, the same winding losses, the same ampere-turns on armatures and field ampere-turns in air-gaps equal to about twice the armature ampere-turns active at the pole corners.

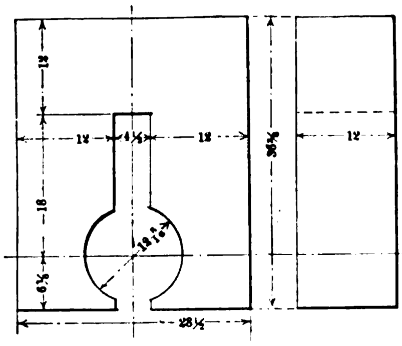
The air-gaps and armature cores of each machine are crossed by 4,320,000 magnetic lines, and allowing a leakage of 25 per cent. the field core must furnish 5,760,000 lines.

---

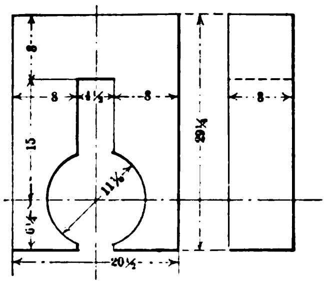
*A paper presented at the 93d meeting of the American Institute of Electrical Engineers, January 16th, 1895.

A wrought-iron field to carry 5,760,000 lines, at 90,000 per inch saturation, requires a section of 64 square inches, which is provided by a core of 8 inches square and a cast-iron field at 40,000 lines per square inch requires a section of 144 square inches provided by a core 12 inches square.

Allowing sufficient length for magnet windings the same air-gap resistance and an armature core of 11 inches diameter for each of these frames, their dimensions will correspond to the following drawings:



Cast-Iron Frame.



Wrought-Iron Frame.

The weights of these frames are :

Wrought-iron frame	1,020 lbs.
Cast-iron frame	2,780 "

For work as shunt motors the wrought-iron machine requires 11,000 ampere-turns in the air-gaps and 2,000 in iron, the cast machine 11,000 ampere-turns in air-gaps and 3,800 in iron.

With 440 watts expended in field coils of each machine, an average length per turn of 38 inches in the coils for wrought iron, and 54 inches in the coils for cast-iron, the weights of these coils are :

Wrought-iron machine	138 lbs. copper.
Cast-iron machine	340 " "

The drum armature for the wrought frame is 11 inches diameter and 8 inches long, that for the cast frame 11 inches diameter and 12 inches long, without allowance for shaft hole.

The weights for armatures are :

Wrought-iron machine	211 lbs. disk.
Cast-iron machine	316 " "

With a loss at full load of 490 watts in the armature winding for wrought-iron machine, and 464 watts in the armature winding for cast-iron machine, these windings require in

Wrought-iron machine	49 lbs. copper.
Cast-iron machine	71 " "

The above indicates plainly the great saving of wrought over cast iron in dynamo construction.

From the user's standpoint the wrought-iron machine seems preferable on account of its lesser weight and bulk, this difference being especially marked in machines for direct connection to engines, and other purposes where slow speed is necessary.

The Swiss Bundesrath is urging the construction of an electric railroad to the very summit of the famous Jungfrau. It is proposed to operate the road by power to be obtained from the Grindelwald glacier or from the water of the Tummel River. Ruskin would have thought this far more sacrilegiously and profanely modern than even the Joppa and Jerusalem Railroad, whose newsboys sell popcorn balls and prize candy to pilgrims on their way to Calvary.

THE DISTRIBUTION OF ENERGY IN THE SPECTRUM OF THE GLOW LAMP.*

(Preliminary Measurements.)

BY EDWARD L. NICHOLS.

IV.

Mr. Nichols, in his paper, has described briefly the calibration of the bi-sulphide prism. Since, in work of the kind under consideration, the accuracy of this calibration is of the utmost importance for the determination of wave lengths in the infra-red, it may be well to give some additional details. The containing vessel of the prism consisted of a block of cast-iron bored through so as to give a cylindrical opening about 4 cm. in diameter. The glass faces of the prism were cemented over this opening, forming an angle of almost exactly 60°. Since the refractive index of carbon bi-sulphide changes greatly with the temperature, it was necessary to have an accurate knowledge of the temperature of the contents of the prism at the time when each measurement was made. The method finally adopted for this purpose was as follows :

At the back of the prism a small pocket was constructed, one side of which was formed by the iron wall of the prism itself. Within this a delicate thermometer was inserted, the bulb of which was surrounded by water.

The dark room within which the spectrometer was mounted was an inside room of the laboratory, containing only one opening, that, viz., through which the rays from the incandescent lamp, which it was our purpose to study, reached the collimator lens of the spectrometer. The temperature changes in this room were very slow, and a comparison of the readings of the thermometer with those of a similar instrument, the bulb of which was placed within the liquid of the prism itself, showed that the difference of temperature within and without, through the very slight range to which both would be subjected, was negligible. Having satisfied ourselves that the indications of the thermometer in the water pocket at the back of the prism might be taken, the other thermometer was withdrawn and the prism was sealed up. Readings of the remaining thermometer were made before and after each set of readings.

The prism was standardized for a temperature of 23.5° C., a reading which represented very nearly the mean temperature of the room, and all observations were reduced to this temperature. The entire range to which the prism was subjected in the course of the measurements was about 3°. The indices of refraction of the prism were determined by Mr. Nichols with great care for temperatures lying within the above-mentioned range, the wave-lengths selected for this purpose being those of the C and F lines of Fraunhofer. The results of this calibration, which are given in Table I of Mr. Nichols's paper, are in close agreement with similar determinations made by Wüllner.

The method of calibration consisted in determining with all possible accuracy the Cauchy equation of the prism from the indices of refraction at the standard temperature for wave-lengths corresponding to the lines A, B, C, and *b* of Fraunhofer. By means of the equation thus obtained a curve was platted extending to the wave-lengths in the infra-red which we wished to measure. This method of determining the longer waves is less satisfactory in some respects than that made use of by Mouton and afterwards by Rubens, but it was believed that the errors thus introduced would not be important in comparison with those which result from other sources.

V.

Briefly stated, the method of experimenting was as follows :

The thermopile already described was placed in close circuit with the galvanometer, the latter instrument having been sensitized to a degree found by previous trials to suffice for the exploration of the region to be tested. The spectrometer was then set to a circle reading corresponding, at normal temperature, to the wave-length in question. The thermometer was then read, the time noted, and the inner room was closed, not to be entered again until the measurements for that region of the spectrum had been completed.

The thermal disturbances produced in the course of these preliminary adjustments lasted in uncontrollable intensity for about thirty minutes, after which time it became possible to bring the galvanometer needle to a position such as to render the scale visible to an observer at the telescope. The drift, still very rapid, would then diminish in the course of ten minutes more to a state of comparative repose, such that readings for the ballistic throw could be obtained. The next step was to close the lamp circuit and to read volts and amperes. The galvanometer was then brought to the proper part of the scale and preliminary calibrating throws were taken. For the purpose of calibration a subsidiary coil was used. This coil was mounted permanently about twenty centimeters behind the needles. It could be thrown into shunt circuit with a compensated resistance through which flowed a very steady current from a storage battery. The current was measured from time to time by means of an accurate mil-ammeter. The swing due to the closing of the circuit of the subsidiary coil gave the relative sensitiveness of the galvanometer. Such calibrations were made before and after every reading of the thermopile throws, and thus all the determinations were rendered reducible to a common scale, although the figure of merit of the galvanometer varied greatly in the course of the experiments.

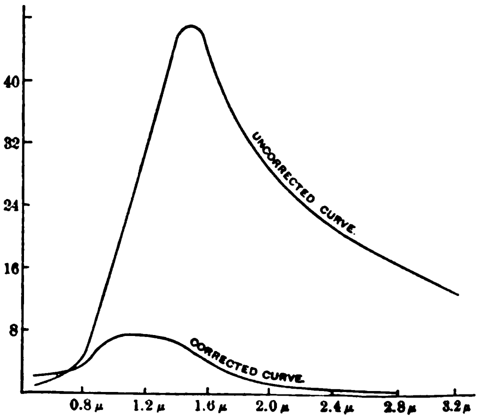


Fig. 6.

After the completion of the preliminary calibration, the radiation measurements were begun, sets of five throws being taken for each condition of the lamp, which was changed stepwise between each set until the entire range to be covered had been included.

When all the readings to be made for the region of the spectrum to which the thermopile was exposed had been completed, the inner room was entered, the thermometer was read and the time noted. The spectroscope was then set to a new wave-length, and after thermal equilibrium had again established itself, the operations above described were repeated. In this way the entire infra-red spectrum between 0.8 μ and 3.0 μ was explored.

The data thus obtained were reduced in the following manner :

---

* "Physical Review."

(1) All deflections were brought to a common scale by reference to the continually repeated calibration throws.

(2) Wave-lengths were determined by correcting the values corresponding to the circle readings of the spectroscope for temperature. These corrections were obtained graphically from calibration curves platted to a large scale.

(3) The deflections were corrected for the width of the face of the thermopile. This was a most important correction, since, owing to the fact that the spectrum was prismatic instead of being normal, the surface of the pile received radiation from a larger and larger number of waves as the wave-lengths increased.

To be comparable one with another in different parts of the spectrum, the deflections should be those obtained by exposure of a surface varying in width with its position, in such a manner as always to receive radiation from a region of unit breadth, measured in wave-lengths. This correction it was possible to apply with satisfactory approximation up to wave-length 3 μ. How important this correction was will appear from Fig. 6, in which a corrected and uncorrected curve are platted to a common scale. In this diagram the width of the thermopile is taken as normal for the region of the D line.

The two lamps described in the second section of this paper were measured throughout a range of temperatures from the red heat upwards to a condition of incandescence beyond which they could not be carried without rapid deterioration. The corrected results are given in the following tables:

Of these two sets of measurements, those upon the lamp with the bright filament were the more complete, being carried down to temperatures much below the red heat. The results may be treated graphically in either of two ways:

(1) By the construction of curves with intensities as ordinates and electrical activity expressed in watts as abscissas, each curve representing a separate wave-length.

(2) By platting intensities as ordinates and wave-lengths as abscissas.

Curves obtained by the former method show the rise in intensity for each wave-length with increase in the energy expended in the lamp. These curves are very similar in form to those for the radiation of platinum as a function of the temperature, as measured by the writer* and also by Violle.

The curves of the second type are shown in Fig. 7, which shows the distribution of energy in the spectrum of the lamp with lampblack-coated filament (1_b), and in Fig. 8, which gives similar curves for the lamp with bright filament (1_a).* It will be seen that the distribution is very different in the two cases, the maximum in the case of the latter being nearer the visible spectrum. Were both sets of curves extended to the shorter wave-lengths, it would unquestionably be found that the area of the portions lying within the range of the luminous rays is larger in the case of bright filaments, a result which would afford a complete explanation of the superiority of such filaments in the production of light, as shown by Evans in the experiments already described.

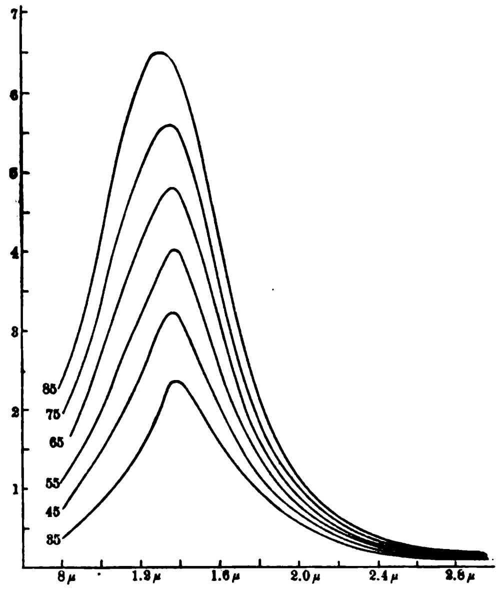

FIG. 7.

Similar measurements to the above were made upon a commercial lamp with untreated filament bamboo. The lamp in question is the one used as a reference light in the experiments of E. F. Nichols upon the infra-red.† It will be seen, by reference to his curves, that the distribution in the spectrum of this lamp was in every respect similar to that in the spectrum of lamp 1_b.

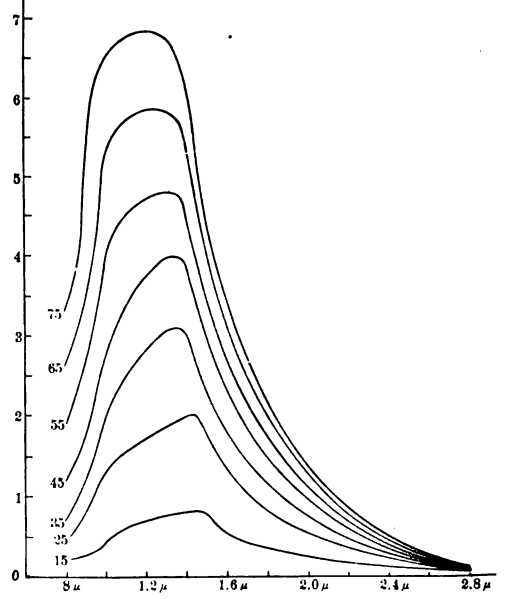

FIG. 8.

The complete investigation of the problem with which this paper deals would involve the direct measurement of the temperatures of the radiating surface. In such an investigation, to which the experiments here described are preliminary, the writer is now engaged. The results are to be given in a subsequent article.

---

* Nichols, Ueber das von gluhendem Platinum ausgestrahlte Licht. Gottingen, 1879.

* The only measurements in any way comparable with these, so far as the writer is aware, are those of Abney and Festing. Their curves are, however, platted with scale readings instead of wave lengths as abscissas, so that it is difficult to make any exact comparison.

Prof. Rowland on Modern Theories of Electricity.*

BY PROF. OLIVER LODGE, F.R.S.

A popular exposition should not be judged by too high a standard of rigorous criticism, nor need it always be instructive to specialists in the department of which it treats; but when a man like Henry A. Rowland, of Baltimore, endeavors to expound modern theories in ordinary language to untechnically instructed readers, the effort is always of interest and seldom fails to yield some modicum of instruction.

In the *Engineering Magazine* of New York for the current month, there is an article by Prof. Rowland bearing the title "Modern Theories as to Electricity." He begins by saying that electricity no longer exists; and that nothing is more certain than that electricity is not a fluid; he also speaks of that unfortunate term "electric current," and says that "even the definition of electrical units, as adopted by all scientists, suggests a fluid theory."

For our part we should not like to have expressed ourselves quite so unreservedly as this. To say that electricity no longer exists, though of course it only means that it is the ether which is now claiming the lion's share of attention, is hardly a helpful statement; and we fail to see how the orthodox electrical units are clever enough to suggest a fluid or any other theory.

As a specimen of exposition, the following can hardly be considered extremely luminous:

> "But the question now arises as to how the lines of electric force can be produced in the ether, or, in other words, how bodies can be charged. In the first place, we know that equal quantities of plus and minus electricity are always produced. As an illustration, suppose it is required to charge two balls with electricity. Pass a conducting wire between them, with a galvanic battery in its circuit. The galvanic battery generates the lines of force; these crowd together around it and push each other sideways until their ends are pushed down the wire, and many of them are pushed out upon the balls."

But the following attempt to explain electrification by friction is rather better:

> "We can consider, for instance, in chloride of silver that the atoms of silver are joined to the atoms of chlorine by lines of electrostatic force, which hold them to each other. If, by rubbing the chlorine of silver, we could remove the chloride on the rubber while leaving the silver, we could stretch them asunder, and so fill space with the lines of electrostatic force. According to this theory, then, each atom has a number of lines of force attached to it, and it is only by stretching the atoms apart that we can fill an appreciable space with them, and so cause electrostatic action at a distance. We come to the conclusion, then, that all electrification is originally produced by separating the atoms of bodies from one another . . . by friction . . . or some other manner."

He speaks of an electric current as the sliding of the ends of these electrostatic lines on matter, and on matter always, and he continues, "but as they cannot end in a vacuum they cannot pass through it. Thus we conclude that a vacuum is a perfect non-conductor of electricity."

Here the phrase "pass through it" must be interpreted "*move* through it," or it will mislead a reader into thinking that a vacuum has no dielectric properties; and thus a novel discovery might be worked up by the newspapers, quite as good as the memorable and much puffed "discovery" of Prof. Dewar, that radiant heat was stopped by a vacuum.

Leaving these more or less verbal criticisms, we arrive at a bold and uncompromising statement, several times repeated, regarding the earth's magnetism.

"To account for the earth's magnetism, we must suppose the ether to have such properties that the rotation of ordinary matter in it produces magnetism."

---

* The "Electrician" (London), January 18, 1895.

And, again:

> "The ether must also account for the earth's magnetism. If we assume that magnetic lines of force are simply vortex filaments in the ether, we have only to suppose that the ether is carried around by the rotation of the earth, and we have the explanation needed. The magnetism of the earth would then be simply a whirlpool in the ether."

Now these statements are full of more than doubtful hypotheses. First, that magnetism is certainly due to rotation of something, which, although Thomsonian and Maxwellian, has never been proved; next, that rotating ether is the necessary and sufficient whirling material, whereas all that is known is that rotating electrification is sufficient; and, lastly, that the spinning of matter on its axis magnetizes it, against which may be adduced a crowd of specially-directed experiments, all of them having had a negative result.

Certain arithmetical calculations as to the strain required in the ether, in order to explain known electric and magnetic forces, may be of interest.

> "1st. It must be able to explain electrostatic attraction. These electrostatic forces are mostly rather feeble as we ordinarily see them. Air breaks down and a spark passes when the tension on the ether amounts to about $\frac{1}{100}$ pound to the square inch. It is the air, however, that causes the breakdown. Take the air entirely away, and we then know no limit to this force. In a suitable liquid it may amount to 500 times that in air or 5 lbs. to one square inch, and become a very strong force indeed. In a perfect vacuum the limit is unknown, but it cannot be less than in a liquid, and may thus possibly amount to hundreds, if not thousands, of pounds to the square inch.
>
> "2. It must explain magnetic action. These actions are apparently stronger than electrostatic actions, but in reality they are not necessarily so. A tension on the ether of only a few hundred pounds on the square inch will account for all magnetic attraction that we know of, although we are able to fix no limit to the force the ether will sustain. No signs have ever been discovered of the ether breaking down."

It might be added that to explain gravitation—after a Maxwellian fashion—the stress that must be borne by the ether amounts to hundreds of thousands of atmospheres in the neighborhood of very large lumps of matter such as the sun.

The most instructive statement here is the emphatic perception that it is the air which causes disruptive discharge. It is the residues of air which are responsible for the break down of condensers, as Tesla found; and in absolute vacuum there can be little doubt that all modes of conveyance of electricity, whether conductive or disruptive, must cease. And this is best expressed, as Prof. Rowland himself has done in an above-quoted paragraph, by saying that the very phrase electric charge ceases to be applicable to vacuum; *charge* is absolutely limited to the surface of material atoms, and accordingly where they are absent there cannot possibly be any conveyance of electric charges, such as is involved in a current of any kind.

Another useful remark concerns the velocity of ethereal rotation in a magnetic field, supposing always, as Prof. Rowland evidently does, that such rotation is a certain physical fact. He points out that the speed of rotation can be estimated from the known value of the Verdet constant; in other words, by the amount of the Faraday rotation of the plane of polarization of light in magnetized transparent substances. He says:

> "The velocity of rotation is immense, the plane of polarization rotating in some cases 300,000,000 times per second."

It is a perception of facts of this kind which has deterred the writer, and doubtless other experimenters, from a serious attempt to rotate the plane of polarization by rotating a transparent substance.

With respect to an explanation of gravitation, he shows how far away we still are from any approach to it. One of the difficulties connected with this subject is the necessity for infinite speed of transmission. Nothing less than a practically infinite speed suffices to account for astronomical facts.

The natural conclusion is that the ether must be incompressible, and must transmit this action by some sort of thrust or tension; and certain facts suggest that the ether really is incompressible, or else is insusceptible itself to gravitational forces; viz., the fact that "light passes in a straight line through space even when near one of the larger planets, unless the latter possesses an atmosphere. This could hardly happen unless the ether was entirely incompressible or else possessed no weight."

Lastly, Prof. Rowland deals with the ether as a conveyer of energy; he does not consider it in its function of a great storehouse or reservoir of energy on which the whole activity of the material universe depends; but he points out that it is remarkably competent to convey, and convey rapidly, much more energy than any known form of matter is.

> "The amount of energy which can be transmitted by the ether in this manner is enormous, far exceeding that which can be carried by anything composed of ordinary matter. Thus, take the case of sunlight: on the earth's surface illuminated by strong sunlight a horse-power of energy falls on every square foot. At the surface of the sun the ethereal waves carry energy outward at the rate of nearly 8,000 H. P. per square foot.
>
> "Again, an electric wire as large as a knitting needle, surrounded with a tube half an inch in diameter, in which a perfect vacuum has been made to prevent the escape of electricity, may convey to a distance 1,000 H. P.—indeed, even 10,000 or more horse-power, there being apparently no limit to the amount the ether can carry.
>
> "Compare this with the steam-engine, where only a few hundred horse power requires an enormous and clumsy steam pipe. Or, again, the amount carried by a steel shaft, which, at ordinary rate of speed, would require to be about a foot in diameter to transmit 10,000 H. P."

He concludes by emphasizing once more his belief that magnetism is due to ethereal rotation, and says definitely that "a magnetic line of force is a vortex filament in the ether." The alternative view, championed by Dr. Larmor, that magnetism may be due to flow and electric current to spin, has evidently not yet impressed him as possessing any force or validity. It may be assumed as probable that he has strong reasons for this orthodox Maxwellian belief, and it would be interesting to know them.

He considers magnetism more simple and easy to comprehend than electrostatics, which again must be considered as a thoroughly Maxwellian position, and it is interesting to see how the great foreign philosophers of the world are all slowly coming to recognize the magnitude of this great teacher. Prof. Rowland, indeed, has long recognized it, and it is hard to speak of members of the Anglo Saxon race as foreigners; but their aloofness from insular prejudice and the bonds of the mother country render their adhesion to the English, instead of to one of the many forms of Continental theory, of special interest.

The domain of electrostatics is evidently regarded by Rowland, as it is also by Poincaré, as the least edifying and satisfactory parts of the present theoretical treatment of the subject, regarded from an ethereal point of view, and almost the concluding words of the article now under notice are the following:

> "Electrostatic action is more difficult to explain, and we have hardly got further than the vague idea that it is due to some sort of elastic yielding in the ether.
>
> "Light and radiation in general are explained when we understand clearly magnetic and electrostatic actions as the two are linked together with certainty by Maxwell's theory."

A Notable Discovery in Electricity.

The year 1894 was not remarkable for epoch-making discoveries in science, but was busily occupied in the prosecution of familiar lines of research, with useful applications of existing knowledge as the chief result. Nevertheless, something has been done to widen the intellectual vision and stimulate thought in new directions. Perhaps the most striking original work of the past year was Mr. Philipp Lenard's application in England of Hertz's discovery that metallic films are transparent to the dark rays issuing from the negative pole in the case of electric discharge in a high vacuum. Mr. Lenard closed one end of a vacuum tube with an aluminum film thick enough to resist atmospheric pressure and studied the rays after passage through the metal. The air outside was seen to glow faintly. All the ordinary phosphorescent effects produced by Crookes in a vacuum were thus readily produced in air. These rays from the negative pole, though not affecting the eye and producing no sensation in the skin, are yet photographically active, and to the tongue and nostrils have the taste and smell of ozone.

Unlike the rays of ordinary light they cannot pass through quartz plates, but do pass through metal films which are opaque to light. In respect to air or gas their behavior is equally novel. Ordinary light passes through a gas as if it were a homogeneous medium and becomes dispersed or makes its path visible only in case there are solid particles, such as dust, floating in the gas. But these rays from the negative pole, or "cathode rays," affect the gas molecules as if they were solid particles floating in a continuous medium. In other words, all gases, however transparent to ordinary light, are turpid to cathode rays, and the degree of turpidity depends wholly upon the density or mass of the gas molecules present, irrespective of their chemical character. Oxygen, for example, under a reduced pressure that brings it to the density of hydrogen, is as transparent as hydrogen, while hydrogen, if brought by pressure to the density of oxygen, becomes as turpid as oxygen.

The cathode rays traverse a perfect vacuum with facility. After passing through the aluminum screen their radiation in air stops at a distance of eight tenths of an inch, but in hydrogen it extends to four inches and in a vacuum to fifty-two inches. While the rarest gas disperses the cathode ray into a blur, as a fog disperses an ordinary ray, its movement in a vacuum is in a straight line. But a magnet brought near deflects it. The question of the nature of matter is raised by some of Mr. Lenard's experiments, the experimenter being of opinion that the fact that every gas molecule acts as a solid obstacle to the passage of the cathode rays is a proof that the molecule is only "a function of the ether itself"—virtually that there is no matter, unless the name can be given to ether, a substance that eludes all tests. Prof. J. J. Thompson, on the other hand, finding that the rate of propagation of these phosphorescence-producing cathode rays is much less than that of ordinary light, but about one hundred times as great as that of the hydrogen molecule, solves the difficulty by assuming that electrified gaseous molecules, rather than the ether, are the seat of this mysterious force.

A practical utilization of the cathode rays has been in the Ebert luminescent lamp. The inventor states that a serviceable light can be obtained by means of his lamp with an expenditure of one-two thousandth part of the energy consumed in the acetate unit lamp. Just what weight is to be given to this claim is in doubt, but it is evident that we have in Hertz's discovery and Ebert's lamp a promise of a new method of electric lighting vastly cheaper than those with which we are at present familiar.—*Baltimore Sun.*

LEGAL NOTES.

The Supreme Court of Michigan has rendered a decision against the city of Detroit in the suit brought by the city questioning the right of the Detroit Citizens' Street Railway Company to the use of certain streets for its railway tracks. Chief Justice McGrath in his decision concisely explains the case thus: "A controversy arose between the city of Detroit and the Citizens' Railway Company as to whether the consent of the city had been given in such a manner as to be available to the present company [some individual changes had been made in the company] and binding upon the city, and the city appealed to the courts, where the matter has been determined. The only question litigated was, whether the consent given survived to the present company." The matter has been before the courts for about two years.

Judge Wright, of the Circuit Court at Baltimore, has rendered a decision in the case of Randolph Barton, receiver, against the stockholders of the old Wenstrom Consolidated Dynamo and Motor Company, holding that the directors of the company only were to be held liable for the difference between what they actually paid for the stock of the company and the par value of $100 per share, according to their holdings, for the purpose of paying the creditors of the company. The indebtedness to outside creditors is about $40,000, or possibly $45,000, and the case will now go to an auditor for the purpose of making up an account. Should the creditors' claims allowed be less in the aggregate than the aggregate sum due by the directors upon their stockholdings, they will be assessed per share of stock only to a sufficient extent to meet the claims.

The Appellate Court in Chicago has reversed the order of the Circuit Court restraining the Northern Electric Railway from erecting an electric line on Central avenue. The decision will result in considerable damages to be paid by the Chicago, Milwaukee and St. Paul Railroad Company. Since the granting of the injunction the defendant company has added to its tracks at the crossing point in dispute. The electric road will have to cross forty-five tracks.

Judgments in the Superior Court in Seattle, Wash., continue to pile up against D. T. Denny and his sons. A few days ago defaults were signed in two actions by the Northwest General Electric Company, and one by W. J. Grambs on assigned promissory notes aggregating $84,791, and a confession was made in a suit on a $9,000 promissory note executed to George F. Gund. The notes held by the electric company are dated March 1, 1893, and are as follows: Northwest General Electric Company, $24,000; L. H. Griffith ($20,000, $12,000, $10,000, $8,750, $5,250), $56,000; F. T. Blunck, $4,134.75; Jacob Furth, $656.25; total, $84,791. The amount with interest and attorneys' fees is now in the three former cases $97,298.52, and in the Gund case $9,455.62, bringing the grand total to $106,758.12. This sum, together with the confessions in the cases of the Puget Sound National Bank and F. T. Blunck, makes a total of $409,372.58.

In the Federal Court at Indianapolis, on the 31st ult., Judge Baker entered a decree of foreclosure and ordered the sale of the Queen City Electric Street Railroad at Marion, Ind. The decree was entered upon the suit of the Metropolitan Trust Company of New York, and the judgment was for $79,551.88. Howard Cale has been appointed special master in chancery to sell the road on March 6. Russell B. Harrison has a claim against the company for $11,000.

The suit of the city of Lockport, N. Y., vs. the Lock City Electric Street Railroad Company to obtain the forfeiture bond of $6,500 and determine the rights of the city in the property of the company and its franchise will be tried in the term of Supreme Court which convenes at Lockport this month.

In the suit brought in Jersey City by E. J. Stanley and J. C. D. Outwater against Edward J. Weiss to recover $2,000 advanced to Weiss to have his invention of an electric motor patented the jury gave a verdict in favor of the defendant. Weiss claimed for his invention that with 200 feet of coil he could produce as much motive power as 2,000 feet used in the ordinary motor. He told Stanley and Outwater of his invention and they entered into a partnership with him and advanced money towards getting it patented. Weiss testified that he had not secured a patent because a lawyer had told him it was not patentable. Experts testified that the invention will do all that the inventor claims for it. Weiss proposes to institute proceedings to cancel the agreement by which Outwater and Stanley were each to receive one-third of the profits of the invention.

Boston Notes.

The West End Railway officials and their employees are discussing an agreement for the current year. The men have submitted a draft agreement making the pay of motormen, drivers and conductors $2.50 per day of nine hours. The best of feeling thus far has prevailed between the conferrees, and it is believed these terms will ultimately be conceded by the company.

An electric snow plow broke loose a few nights ago at Haverhill, Mass., through the failure of the brakes to operate. The machine went on the rampage like a flash, dashing down a steep declivity on Main street and ending its mad career by running into a drug store. The men in charge jumped and escaped injury.

The Swedish Electric Singers, all of whom are employees at the Lynn works of the General Electric Company, held a banquet in Electric Hall last Friday evening. The gathering was a success in every respect. The hall and tables were very tastefully decorated. There were many guests, some fine music, and singing and dancing until a late hour.

The fight over the franchise for the construction of a local line between rival railway companies in Quincy and Weymouth waxed very warm last week, the citizens of the latter town being in a state of excitement over charges made by opposing counsel that the Weymouth company is an illegal corporation. The selectmen are considering how best to dispose of the franchise.

The Edison Illuminating Company of Boston has just closed a long time lease on a piece of land in Bumstead Court, and will use it for the site of an addition to its fine central station on Head Place. A four-story building is to be erected on the site, which will be used for a storage battery plant that will be somewhat of a novelty. At the present time the company has at its Atlantic avenue central station a small battery plant capable of running 6,800 lights for about 2½ hours, while the one to be erected in Bumstead Court will be of sufficient capacity to run something like 30,000 lamps for the same time. The battery plant is of German type, and by its use the company hopes to effect a considerable saving in operating the station.

The extraordinary slump in General Electric stock has started speculators on the outlook for the final tumble that everyone is now satisfied the Trust as a whole will take, the result of which will be a complete smash-up. Reorganization and a capital reduction of at least 50 per cent. are now suggested, and insisted upon as the only possible chance of saving the concern from being completely wiped out of existence.

The case of George F. Bowles and wife of Lynn against the Worcester, Leicester and Spencer Street Railway Company, which has been tried twice and verdicts aggregating $5,983 awarded, not having been appealed, the company will have to pay. The original claims were for $20,000 and $10,000 on account of permanent injuries received by Mrs. Bowles on August 28, 1892.

Personal.

Mr. James S. Humbird, president of the Washington Carbon Company, has been elected a director of the Baltimore and Ohio Railroad at Pittsburg.

General News.

What is Going on in the Electrical World.

San Francisco.—The Market Street Railway Company has decided to encircle the city and county of San Francisco with an electric railroad.

Portland, Me.—The Portland Railroad Company are preparing to do some rapid work after they get permission to change their lines over to electricity.

Charlottesville, Va.—The Electric Street Car Company has purchased the horse car line, and will replace it with electric equipment as soon as the weather will permit.

Croton, N. Y.—Messrs. Freeman & VanDuyne have received permission to erect poles and string wires for the purpose of furnishing electric lights in Croton.

Saugatuck, Mich.—Contracts have been made here for the placing of electric light plants in the steamers Saugatuck and Bon Ami. Both boats will be fitted with Westinghouse engines and dynamos.

Washington, D. C.—Fourteen electric cars were burned by a fire at the Brightwood Street Railway Company's car stables on the night of the 25th ult. The power house and boiler rooms were saved.

Saginaw, Mich.—The Saginaw and Bay City Street Railway Company has been granted a franchise by the common council of Saginaw, and will now press its request at Bay City for a similar favor.

Nyack, N. Y.—The Nyack Traction Company has been granted a franchise for an electric railway in this village and also in Upper Nyack. The River and Valley Traction Company withdrew its application.

Richmond, Va.—The proposition to appropriate $150,000 to establish a city electric light plant, has been defeated in committee. The lighting of the city remains in the hands of a private company.

Fort Clark, Ill.—F. W. Horne, of Chicago, president of the Fort Clark Electric Railway Company, has been appointed receiver of the company under bond of $20,000 with the American Surety Company.

Chicago.—An ordinance has been introduced in the city council authorizing a conduit electric system from Monroe to 69th street and from Halstead street to the lake. It was referred to the committee on railroads.

Readsboro, Vt.—W. S. Kelley, of the General Electric Company, has bought Howe's pond and over 500 acres of land in Readsboro. It is believed that the electric company will build a large electric plant here.

Shelbyville, Tenn.—In connection with the waterworks, the construction of which is under contract, it is now proposed to put in an electric light plant, both arc and incandescent, for the better lighting of this town.

Montreal, Can.—The Royal Electric Company has appointed as general manager in place of Chas. W. Hagar, retired, W. H. Browne, late general manager of the United Edison Illuminating Company of New York.

Allegheny City, Pa.—Mayor Kennedy has signed the resolution awarding the contract for the lighting plant to the Western Electric Company. Mr. Chase, the Western's representative, said work would begin at once.

Bangor, Me.—The promoters of the new Bangor and Oldtown electric road say that "it is worth $10,000 annually to have on their line the city cemetery and the new insane hospital." A rather gruesome consideration.

Weyauwega, Wis.—At the special election held here on the 28th ult., the electric light project was carried almost unanimously. Weed, Gumaer & Company offer to furnish arc lights at $45 per annum each, which proposition will probably be accepted by the village board.

Biloxi, Miss.—At a meeting of the directors of the Biloxi Electric Light plant, E. G. Burklin, the manager, reported that the success of the plant warranted a dividend of 10 per cent. This is more noticeable from the fact that the plant has met with serious drawbacks during the year by accidents.

St. Paul, Minn.—A new electric interurban line is proposed, connecting this city with Minneapolis, either that or to remodel the Fourth Street and Selby Avenue Cable Line and its electric extension and run the whole thing through to Minneapolis.

Jamaica, L. I.—The town commissioners have given the Long Island Electric Railway Company permission to build, operate and maintain a surface railroad, to be run by electricity, on Cherry avenue, Foster's meadow and to and through private property from New York avenue to Springfield.

Kansas City, Mo.—The Gill-Alexander Electric Manufacturing Company has filed a deed of trust with the recorder of deeds, secured on all its property, consisting of patents, contracts, leases, machinery and all fixtures and appurtenances, in favor of A. P. Marty, trustee, to secure a bond issue of $20,000.

Quincy, Ill.—The joint ordinance and light committee have reported an ordinance granting a franchise to the Empire Light and Power Company. The council approved the report. The Empire Company, if it accepts the franchise granted, will enter into competition with the present electric light company.

St. Joseph, Mo.—An ordinance has been presented to the council granting to Walter C. Stewart and his associates the right to construct and operate an electric lighting plant. An ordinance granting Huston Wyeth a similar privilege is still before the council. Mr. Stewart and his associates desire a fifty-year franchise.

Phenix City, Ga.—A charter has been granted the Drake & Stratton Company and the preliminary surveys made for the construction of an electric railroad in this city, and another line along the Crawford road from the Fourteenth street bridge to the Chattahoochee Brewing Company's plant at Columbus.

Brooklyn, N. Y.—The strike of the trolley roads employees is practically ended, the companies having succeeded in filling the places of the strikers on most of their lines. Military protection has been withdrawn, and the lines are now left to the vigilance of the police. The cost of the strike to the city, companies and strikers is estimated at a million and a half.

Stroudsburg, Pa.—Among the latest rumors here is one to the effect that a charter will be applied for for a road to connect at Stroudsburg with the Bangor, Pen Argyl and Wind Gap Electric Railway Company's line, and run over to Lake Poponoming. Henry Fulmer, of Easton, is one of the principal projectors of this new road.

Geneseo, N. Y.—The proposition to build a six-mile electric railroad from Geneseo to Long Point on Conesus Lake to be used during the summer camping and excursion season is being seriously considered by the citizens and the Geneseo Electric Light Company, which has more power than is necessary for lighting the streets and other purposes.

Norwalk, O.—The Norwalk electric light plant, which was placed in the hands of assignees two years ago by request of creditors, has been ordered sold at public auction by Judge Thomas, the sale to take place March 1. The principal creditors are the Huron County Banking Company, who hold $11,000 claims, and R. W. Huntington, of Cleveland, who has claims of about $7,000.

Binghamton, N. Y.—G. W. Davenport, of Boston, and Eugene Griffin, of New York, have been appointed a committee to reorganize the Binghamton General Electric Company. The attorneys of the General Electric Company of Schenectady applied to the court for the discharge of the receiver of the Binghamton Company, and the application has been granted.

Rochester, N. Y.—A new locomotive has just been turned out at the Lincoln Park shops of the B., R. and P. Railway which is fitted with all the modern improvements including an electric headlight capable of lighting the track for nearly two miles. The power for the headlight is furnished by a motor placed back of it and directly in front of the smokestack.

Ottawa, Ill.—The General Electric Company has sold the Ottawa Electric Street Railway to a home syndicate represented by Mayor Schoch, for $40,000 in bonds, the condition of the contract requiring the local men to invest $20,000 additional in improvements. The property will be transferred March 1. It originally cost $115,000 and was the first electric road put down in Illinois.

Elkhart, Ind.—General Manager Myton, of the Indiana Electric Railway, has closed a contract for the purchase of seven miles of steel rails for the completion of the line between this city and Goshen. He has also purchased twenty-five acres of land near the county seat for the purpose of erecting a power house and station.

Hartford, Conn.—The bill forbidding electric railways to cross steam car lines at grade, having passed the Connecticut Legislature, will prove detrimental to the electric roads; but why cannot electric lifts for the cars be erected where the traffic is sufficient to warrant the outlay? Is there not inventive genius enough in the Nutmeg State to devise a method?

New York.—Russell Sage lately, speaking of the future of the Manhattan Elevated Railroad, says: "It is certain that in the very near future we shall replace steam by electricity, and will then be able to accomplish much which for the moment seems impossible. I have always been in favor of electricity; also of elevators at the stations. In time we shall lift passengers to the stations from the streets."

Boonsboro, Md.—A meeting was held last week in the interest of a reorganization of the Boonsboro and Keedysville Electric Railway. It is estimated that it will take $26,000 for its construction. Dr. A. W. Lakin, S. S. Davis, Samuel Knode, A. C. Huffer, J. C. Brining, D. W. Barkman and H. S. Beard were appointed a committee to solicit stock subscriptions.

Pittsburg, Pa.—The Essen Coal Company of Pittsburg has closed a contract with the Independent Electric Company of Chicago for a complete electric plant for mining and hauling the coal in its mines at Hazeltine, Pa. This is said to be the largest plant ever put into a bituminous mine. It will cost between $65,000 and $75,000, and is intended to produce 2,400 tons of mine run coal each day.

Greeley, Col.—A company is being organized for the purpose of furnishing light and power for this city and to operate a system of electric railroads running throughout the country about Greeley, the idea being to transport not only passengers but freight to and from the city. The company proposes to dam the Poudre River several miles up and conduct the water in pipes to the works.

Lambertville, N. J.—Benjamin Mitchell of this place has invented a rat trap from which he expects great things. His idea is that it will find favor with the owners of large buildings who generate their own electric power for lighting purposes. A piece of cheese is attached to the end of a wire. To reach the cheese the rat has to step on a conductor, and when he touches the cheese he completes the circuit—and his career.

Toronto, Can.—Application will be made to the Legislature of Ontario at its next session for a charter for the construction of radial electric railways from this city to different points in the county of Elgin. The company is to be known as the St. Thomas Radial Electric Railway Company, and the applicants are K. W. McKay, Jas. A. Bell, W. R. Jackson, John Campbell, A. E. Domville, James Fulton, John Slacey, C. B. Hunt, E. R. Cameron.

Alexandria, Va.—The Mount Vernon Electric Railway Company is pushing the building of its road from Alexandria City northerly toward the Aqueduct bridge, and the authorities of the road say they expect to reach that point by May or June next. The Washington, Arlington and Falls Church Railroad Company is also grading its road from the Aqueduct bridge to the Arlington estate and surveying and obtaining the rights of way from land owners from Arlington on to Falls Church.

Oxford, Pa.—The prospect is favorable for the early building of an electric railway between Oxford and Newark, Del.—Preliminary movements towards establishing an electric plant at Pine Grove, on the Octoraro, about three miles west of Oxford, have been made. It is stated that 1,000 to 1,400 H. P. can be generated by the water power. The Octoraro flows into the Susquehanna near Rowlandville, Cecil County, Md.

Gilman, Col.—The Tip Top Mining Company has purchased the electric plant on the Eagle River, west of Red Cliff, formerly owned by Charles J. Taylor and others, and will utilize it for the operation of the mill built by it last summer. The plant has been idle for several months because of a disagreement among the owners. Its former use was to furnish the town of Gilman and the mines around it with light. It is operated by water power and is equipped to supply both light and power. The new purchasers paid about $20,000.

Buffalo, N. Y.—A municipal electrical bureau in connection with the Board of Public Works is about to be established here.—The Cataract Construction Company has secured a right of way from Tonawanda to the city line of Buffalo. The route is along the west side of the New York Central's tracks.—The Buffalo Lumber Exchange have passed a series of resolutions favoring generous treatment to the parties who are asking a franchise for the distribution in this city of Niagara Falls power.

Albany, N. Y.—Bills have been introduced in the Legislature having in view the cancelling of the charters of some of the electric railway companies in Brooklyn for violations of their charters in failing to run cars during the strike, and for other reasons that the managers of the strike deem sufficient.—A bill has been introduced in the Assembly compelling street railways to construct on the front of every electric car a guard, fender or sweep raised not more than five inches above the surface of the road.

Gardiner, Me.—The scheme to incorporate the Maine Water and Electric Power Company is said to be one indirect outcome of the building of the Wiscasset and Quebec railway. Mr. Wm. Doe, of Dukesport, Pa., who represents Pennsylvania capitalists, is the principal mover in the enterprise. On the Sheepscot, above Wiscasset, are numerous water powers, and Mr. Doe and his associates have a plan of buying up these privileges and using them to furnish the power to supply electric lighting, and to run street railways in the towns near the river, and also to supply water to the towns.

Herkimer, N. Y.—The formal transfer of the present Herkimer and Mohawk and Ilion street railroads to R. J. McKeever and Jacob L. Hees, supposed to represent the New York Central Railroad, has been completed. The new company will be known as the Herkimer, Mohawk, Ilion and Frankfort Railway Company. J. L. Hees, of Fonda, has been elected president, R. J. McKeever secretary and treasurer, A. D. L. Baker, of Gloversville, J. L. Hees and James L. Stewart directors. The Central Railroad Company has granted the new company the right to cross its tracks in Herkimer. This is regarded as conclusive proof that the Central helped to consummate the deal.

Philadelphia.—The lines of the Philadelphia Traction Company on which the change from horses to electricity will next be made will be the York and Dauphin and Spring Garden and Wallace street lines. In a few days the overhead work will be completed over the routes named.—The new electric machines for softening Harveyized armor, which were built for the navy at a cost of $30,000, have been tried at Cramps' and officially pronounced successful. It has heretofore been found impossible to drill the necessary holes in the Harveyized plates, and work of this kind has practically been suspended for the past three months.

Peoria, Ill.—A bill has been introduced in the Illinois House of Representatives by Mr. Daugherty, of this city, giving cities power to contract with gas or electric light companies for a period of not exceeding thirty years. In cities where such plants are now in operation the authorities may purchase or lease the same. Before the lease or purchase shall be binding, the question shall first have been submitted to the people at a general election—the ballot specifying the yearly rental if a lease or the consideration price if a purchase. If the proposition is defeated at the polls a resubmission cannot be had for ten months. Cities are empowered to borrow money and levy and collect taxes for the purpose of purchasing or leasing plants and maintaining them.

Jersey City, N. J.—The Consolidated Traction Company of New Jersey, has decided to put freight cars on its lines, and in a short time a regular express business will be established. At present the company has three of the proposed freight cars in operation, carrying supplies for the company. They are similar to the express and baggage cars used on steam railroads.—An electric storage battery placed in each car of the Jersey City line of the Consolidated Traction Company crossing the Newark meadows is used as an adjunct in lighting the cars. Under the former system in use, the slipping of the pole from the trolley wire at once put out the incandescent lamps, and left the passengers in the dark. When this happens now, the storage battery at once comes into play and lights the lamps.

Harrisburg, Pa.—Mr. Woodring has introduced a bill in the House which, if it becomes a law, will enable Philadelphia to manufacture its own electric light and likewise to sell it. The bill provides that the provisions of the act of May 20, 1891, shall be extended to cities of the first, second and third classes. The act of May 20 authorized boroughs to manufacture electricity for commercial purposes, and to erect, purchase or condemn electric light plants and apparatus already established. It gives councils the right to purchase electric light works at such price as may be agreed upon by them and a majority in value of the stockholders of the company. In case of a failure to agree the court can be asked to appoint viewers to assess the value of the plant.

Chattanooga, Tenn.—The plant of the Chattanooga Electric Light Company has been sold to satisfy a judgment of the General Electric Company. The plant was purchased by J. H. Levis, of New York, for $75,000. The company had a bonded indebtedness of $145,000, the larger portion of which was held by the General Electric Company. It is understood that a new company will be formed to run the plant.—An application for a charter for the Chattanooga Light and Power Company has been made by F. V. Brown, D. J. O'Connell, F. F. Wiehl, J. B. Nicklin and Frank Spurlock. This corporation, when the charter is obtained, will be the successor of the present electric light company. The application for the charter asks permission to generate and manufacture electricity and sell the same in all its forms, also for power to manufacture and deal in all kinds of electrical machinery and apparatus.

Yuma, Ariz.—A project of grand proportions in electrical plants is being developed here, and is assuming a shape that promises its fulfilment. It is proposed to establish a great electric plant on the Colorado River, to be run by the current of that stream, to supply power for mining, transporting, milling and reducing ores from the great mineral belts that exist on both sides of the river a few miles above Yuma. Also for pumping water with which to irrigate the lands lying along the river and the great valley to the south and west of Yuma, and to run all kinds of manufacturing machinery and a narrow gauge railroad among the mining camps back from the river, which is proposed to be built to a connection with the Southern Pacific Railroad at El Paso and with the San Diego, Yuma and Phœnix Railroad where it crosses the river at that same point, and on to the great deposits of sulphur in the Cocopa mountain range, thence to the gulf at the mouth of the Colorado River, where it will connect with steamers and sailing vessels along the coast.

Telephone and Telegraph.

The Traction Company is putting in a system of private telephones at Middletown, N. Y.

The long distance telephone line between Madison, Wis., and New York and Washington was opened on the 23d ult., with the usual ceremonies.

Galesville, Wis., and North Bend will, it is alleged, be within speaking distance of each other at an early day. A telephone line is projected to connect them.

William Meter—not a common name—has asked for a telephone franchise at Sheboygan, Wis. Mr. Meter sells the instrument at $30 to the users, charges them at the rate of $1.50 per month and promises them a metallic circuit.

The Magneto Telephone Company of Elwood, Ind., has contracted to put in an exchange of fifty telephones at Frankton, and build a toll line connecting that city with Elwood. Work on the exchange and toll line will begin in a few weeks.

Sumter, S. C., has established a telephone exchange. The work was superintended by G. S. Maxwell of Sumter.

The Police Department of Buffalo, N. Y., will in the near future throw out all the telephones it now has in connection with the local telephone company and put in an independent system which, it is alleged, will be "something of a marvel in the way of efficiency and expediency."

High Point, near Greensboro, N. C., is having a telephone system put in.

A telephone exchange has been established at Thomasville, Ga.

A bill has been reported to the West Virginia House of Representatives taxing telegraph, telephone and express companies.

The recent storm at St. Louis was very damaging to telegraph, telephone, electric light and fire alarm wires. Over 1,100 telephone wires went down and many 'phones burned out. Communication with the outside world by telegraph was entirely cut off.

The Chamber of Commerce at Petersburg, Va., have appointed a committee to look into the subject of cheaper telephone service for that city. The committee were to call a meeting for the purpose of giving a hearing to representatives of various telephone companies who are seeking a franchise.

The Century Telephone Company of New York has asked for permission to establish a telephone line in Peekskill, N. Y. It offers to give the Peekskill public a telephone service just as good as the one they now have and at half the cost.

J. Hummel, of J. Hummel & Co., St. Louis, have promised the citizens to put in a first-class system of telephones in Louisiana, Mo., at a monthly rental of $2 for business houses and $1 for residences. Already 100 subscribers have been obtained.

The Hudson River Telephone Company a few evenings ago transmitted a musical programme over its long distance line from the office at Newburg, N. Y., to audiences assembled at Goshen and Middletown, who returned thanks for the enjoyment they had in listening to the selections, every note of which was heard distinctly at both places.

F. L. Humes has applied for a franchise to put in and operate a telephone plant at Oshkosh, Wis. He proposes to use the Berliner patents that are owned by the Bell Telephone Company, which have been rendered void by a recent decision of the courts, but are still subject to the decision of the U. S. Supreme Court.

A telephone war is imminent in Fort Wayne, Ind. The Harrison Telephone Company and the Fort Wayne District Telegraph Company have consolidated their interests, and will unite all subscribers, franchises and systems to fight the Central Union Telephone Company, originally the old Bell Telephone Company. Telephones are to be put in for $1.50 a month.

Three telephone companies have applied for franchises at Bay City, Mich.—the Harrison, the Standard and the Anthony. The Harrison seemed at last accounts to be most in favor with the committee of council having the matter in charge.

The Gloversville, N. Y., Electric Company are about to organize a local telephone company which, though incorporated as a separate company, will co-operate with the electric company to the extent of using their poles for stringing wires.

A telephone bill to regulate charges to subscribers has been introduced in the New York Assembly by Mr. Gerst, of Buffalo, and in the Upper House by Senator Parsons. The bill will be vigorously advocated by the New York Board of Trade and Transportation. A joint committee was appointed to hear the arguments of advocates and opponents of the bill.

The Citizens' Mutual Telephone Company of Lockport, N. Y., consider the franchise which the council committee have reported favorably objectionable in some respects and want the following modifications made in it: They want it optional with the company to renew the franchise at the end of ten years; they object to furnising poles for the city's fire alarm wires in districts outside of the telephone district; they want three years instead of six months in which to complete the plant, on the ground that delays may be occasioned by reason of suits with the Bell Telephone Company; they object to giving any free telephones to the city. It is thought the differences will be adjusted.

The druggists of Chicago, it is said, have guaranteed the Harrison International Telephone Co. 6,000 subscribers, and work on the new system will begin early in the spring. The packers at the Stock Yards propose to put in an exchange of their own. They are arranging for a new system which shall connect all parts of the yards and which will permit a prompt alarm being sent in in the event of a fire breaking out. The present system is owned by a private corporation and it is a matter of considerable expense to the packers.

A rumor was current a few days ago in Minneapolis to the effect that a large corporation, with Mackay, the bonanza king, at the head, would be formed in the near future for the purpose of establishing and operating telephone exchanges in various cities, to compete with those already established. The same rumor connected the name of J. F. R. Foss, of Minneapolis, with the enterprise, as one of the founders of the new company.

The Columbia Telephone Company of New York intends opening an exchange in Salem, Mass., if permission is granted by the authorities and a sufficient number of subscribers obtained.

At Columbia, S. C., the Postal Telegraph Company is now having all the poles in the city painted an olive green. All the poles of the Western Union lines have already been painted white and the fire alarm poles red.

The Michigan Telphone Company has accepted the new underground wiring ordinance passed by the Grand Rapids Council and will put their wires underground in the spring.

The Department of the Interior at Washington, after examining a number of bids for 118 telephones for the Department, has decided in favor of the Western Telephone Construction Company of Chicago, who agree to furnish a Departmental system of telephones for $5,565.76. Edward E. Clement, of the Patent Office, has been designated to superintend the installation of the system.

A new telephone company has been organized at Johnstown, Pa., and will apply at once for a charter. The new company intend to compete with the Bell system now in operation, and will put their rates at a much lower figure.

A Good Fire-Proof Material for Air Shafts, Elevators, &c.

An interesting test was recently made in the presence of the Building Department of Brooklyn, N. Y., to determine if elevators and air shafts could be rendered fire-proof without bricking them up. The method tried was to plaster on Roebling stiffened wire lath and fill the space between the studding behind the lath with Mineral Wool. The results were highly satisfactory, as the 20-foot shaft or chimney was found intact on examination after a brisk fire had burned underneath it for over half an hour. The corrugated copper gaskets manufactured by the United States Mineral Wool Company of New York have enjoyed large sales recently among electric and similar plants, among which may be mentioned the Philadelphia Traction Company, Electric Traction of Philadelphia, Nassau Electric Railroad Company, Brooklyn, N. Y., Allegheny Traction Company, Allegheny, City, Pa., Carnegie Steel Company and Messrs. S. Shoenberger & Co., Pittsburg, Pa. Samples for tests free from the manufacturers.

A New Catalogue.

The old established house of Wallace & Sons, Brass and Copper Rolling Mills, with sample rooms and warehouses at 28 Chambers and 5 Reade streets, New York, and mills at Ansonia, Conn., are about to issue a new Illustrated Catalogue. Their previous efforts in this direction have met with the highest commendation, and we feel sure that their present issue will demonstrate the progressive position this house has for nearly half a century maintained in the Brass and Copper trade.

The proof-sheets show that the book will be a very acceptable addition to the catalogue libraries of hardware merchants, metal workers, etc., etc., and will, on account of its complete price-lists of different articles, as well as its tables of measurements, weights, etc., etc., become a standard book of reference for dealers in their line.

Special attention has been given to details, particularly in revising various price-lists hitherto more or less confusing, and these changes, together with the profuse illustration of the various articles they manufacture, make everything quite clear even to those who may not be thoroughly familiar with the business. The book is also illustrated with cuts showing the improved manner of packing various articles for the convenience and utility of the shelf-hardware trade, such as Star Brand Copper Rivets and Burs, Copper Tacks and Nails, Spelter Solder, etc., etc.

Several pages in the back of the Catalogue are devoted to tables of weights, measurements, etc., etc., of different metals such as Sheet Copper, Seamless Brass and Copper Tubing, Brass and Copper Rods, etc., etc., so as to enable the trade to estimate on goods of this description comprehensively.

The Metropolitan Electric Company, 186-188 Fifth avenue, Chicago, has just taken the agency for the American Carbon Company's products and will carry a full line of this celebrated Carbon. They will have their stock in in a very few days and will be able to meet the demands of the market. This adds another high-class specialty to the Metropolitan Company's list.

RECENT COMPANY ELECTIONS.

Syracuse Street Railroad Company, Syracuse, N. Y. President, G. E. Herrick; vice-president, W. R. Kimball; treasurer, Theo. H. Conderman; secretary, William P. Gannon. Directors: W. R. Kimball, Paul T. Brady and William P. Gannon, of Syracuse; Charles R. Flint and L. R. McClymonds, of New York City; Theo. H. Conderman, of Philadelphia, and W. H. Hazard, H. Clark Ford and G. E. Herrick, of Cleveland.

Berlin Iron Bridge Company, East Berlin, Conn. The following Board of Directors was elected at the stockholders' meeting on January 29: Charles M. Jarvis, Geo. H. Sage, F. L. Wilcox and Burr K. Field, of Berlin, Conn.; S. Howard Wilcox, of Brooklyn, N. Y.; Julius Burr, of East Berlin, Conn., and H. Peck, of Waterbury, Conn. By vote of the stockholders the capital stock of the company was increased from $300,000 to $500,000. The new issue of stock has all been taken by the old stockholders.

Standard Underground Cable Company, Pittsburg, Pa. The Board of Directors held their first regular meeting after the annual stockholders' meeting on January 26, and elected the following executive officers of the company for the ensuing year: President, George Westinghouse, Jr.; vice president and general manager, Joseph J. Marsh; secretary and treasurer, Frank A. Rinehart; auditor, Charles M. Hagen. At the annual meeting of the stockholders Joseph W. Marsh was re-elected as one of the directors in the company. Mr. Marsh is now entering upon the fourteenth year of his connection with this successful corporation, during most of which time he has been its general manager.

Seneca Electric Company, Seneca Falls, N.Y. Directors: S. D. Green, N. S. Wilcox, H. H. Crowell, P. H. VanAuken and B. F. Peach, Jr. A meeting will be held in a few days when it is expected that the reorganization of the company will be completed and important changes made in the management.

Pittsburg Traction Company, Pittsburg, Pa. President, G. W. Elkins, Philadelphia; vice-president, C. L. Magee, Pittsburg; secretary and treasurer, J. G. Traggard. Directors: G. W. Elkins, P. A. B. Widener, W. L. Elkins, C. L. Magee, William Flinn and George C. Wilson.

Mt. Mansfield Electric Railroad Company, Mt. Mansfield, Vt. General Manager, P. D. Pike; auditors, A. C. Raymond, H. W. Barrows and J. A. Stafford. Directors: P. D. Pike, F. O. Burt, W. P. Dillingham, C. L. McMahon, L. C. Moody, C. E. Burt and E. D. Blackwell.

Central Wisconsin Electric Railway, Oshkosh, Wis. Directors: George H. Ketcham, George J. Kobusch, Otto von Schrader, F. M. Ohl, T. E. Ryan, C. T. Lewis and M. L. Campbell.

People's Traction Company, New York City (organized last week). Directors: Franklin A. Wilcox, Edward H. Hobbs, John A. Bensel, Martin J. Keogh, Daniel F. Cohalan, Charles B. Hobbs, John Foley, Jr., Edward Hassett and J. Clarence Davis.

Mascoutah Electric Light Company, Mascoutah, Ill. President, George Postel; vice-president, Philip Henry Postel; secretary, Henry R. Hagist; treasurer, J. E. Postel.

Harrisburg Electric Company, Harrisburg, Pa. President, E. Z. Wallower; secretary and treasurer, H. W. Stone; general manager, C. H. Kinter; superintendent, W. R. Fitzpatrick. Directors: E. Z. Wallower, John I. Beggs, W. O. Bishop, Harris Cohen, T. H. Heist, E. B. Mitchell, H. T. Ross, H. J. Stewart, Joseph Strouse, B. M. Nead and Horace B. Mitchell.

Wissahickon Electric Railway Company, Philadelphia. President, Peter P. Liebert; vice-president, William Flanagan; secretary and treasurer, John Flanagan. Directors: Peter P. Liebert, William Johnston, James Christie, L. M. Jones, John Kenworthy, Benjamin Kenworthy and W. H. Flanagan.

City and Suburban Railway Company, Baltimore, Md. Directors: Nelson Perin, George C. Jenkins, George A. von Lingen, Wm. P. Harvey, Wm. A. Marburg, B. F. Deford and Edward L. Bartlett. The three last named are new members of the board and take the places of John K. Cowen, E. J. D. Cross and Frank Perin, who declined re-election. The stockholders voted to increase the capital stock from $3,000,000 to $4,000,000.

Edison Electric Illuminating Company, Brooklyn, N. Y. Directors: Frank L. Babbott, Le Grand Beers, Charles E. Crowell, Ethan Allen Doty, Julian D. Fairchild, C. N. Hoagland, Darwin R. James, J. G. Jenkins, Martin Joost, Lowell M. Palmer, Edwin Packard, George Foster Peabody and George H. Southard.

Clyde Electric Light Company, Clyde, N. Y. President, D. M. Wright; vice-president, Nathan Shaw; secretary and treasurer, Edward M. McIntyre. Directors: D. M. Wright, Nathan Shaw, Calvin McIntyre, Charles H. Ford, E. M. McIntyre.

Centralia Electric Light and Gas Company, Centralia, Ill. Directors: C. C. Davis, E. S. Condit, G. L. Pittenger, F. Kohl, Jacob Kohl, Seymour Andrews, G. E. Eis and S. Warner.

Brodie Electric Company, Manchester, N. H. President, J. Brodie Smith; treasurer, Walter G. Africa; general manager, Albert L. Clough.

INCORPORATIONS.

The Compton Electric Service Company (incorporated in W. Va.), New York, N. Y.—to manufacture and vend electrical and mechanical devices, appliances, etc. Capital stock, $300,000. Promoters: Geo. L. Thomas, Baltimore, Md.; Melvin Compton, Newark, N. J.; J. Fred. Glasby, Elizabeth, N. J.

The Fort Madison Water Company, Jersey City, N. J.—to construct, maintain and operate water works, gas works and electric light works. Capital stock, $275,000. Promoters: Alfred C. Brown, Louis Hallock, Jr., Rob't H. Dillingham, Herbert F. Hatch, East Orange, N. J.; Charles B. Brown, Jersey City, N. J.

The Westchester County Central Electric Railway, White Plains, N. Y.—to build and operate a street surface road in the county of Westchester. Capital stock, $75,000. Promoters: F. H. Reed, C. A. Johnson, C. M. Nichols, New York City.

The Frederick-McCabe Construction Company, Baltimore, Md.—to carry on a general contracting and engineering business, making a specialty of constructing electric railways and plants, and to manufacture and sell dynamos, motors, lights, accumulators, etc. Capital stock, $50,000. Incorporators: James F. McCabe, Lawrence N. Frederick, Frank H. Sloan, Lawrence P. McCabe, Francis E. Yewell, William G. Stocksdale and Frank Slingluff.

The Mountain Stream Water Company, San Diego, Cal.—to deal in water and water rights; operate water works; operate electric light and power plants. Capital stock, $10,000,000. Promoters: J. M. Howells, Chicago, Ill.; Jno. D. Works, Lewis R. Works, San Diego.

The Lorain and Wellington Railway Company, Lorain, Ohio—to construct and operate a street railroad, to be operated by electricity or other motive power, between Lorain and Wellington, Ohio; to furnish electric light, power and heat, etc. Capital stock, $100,000. Promoters: H. C. Redington, E. M. Pierce, Jno. Staug, Q. Gillmore, J. W. Steele, O. F. Carter, Jas. Nicholl, Jr.

The York Light and Power Company, York, Neb.—to furnish light and power by the use of gas or electricity. Capital stock, $12,000. Promoters: H. C. Page, Geo. W. Shuck, S. H. Sedgwick, Geo. R. Reed.

The St. Louis and Jefferson Barracks Railway Company, St. Louis, Mo.—to construct and operate an electric railway line between St. Louis and Jefferson Barracks. Capital stock, $30,000.

The Nikola Tesla Company, New York City—to manufacture and sell machinery, generators, motors, electrical apparatus, etc. Capital stock, $5,000. Directors: Edward D. Adams, Ernest K. Adams, Alfred S. Brown and William B. Rankin, of New York City, and Charles F. Coaney, of Summit, N. J.

The Boynton Multivolt Battery Company, Brooklyn, N. Y.—to manufacture and sell electrical apparatus, batteries, etc., photographic supplies and materials, etc. Capital stock, $10,000. Directors: Edward S. Boynton, of Brooklyn; Abraham Strauss, Peter Kemble and Charles H. Brigham, of New York City.

The Central Wisconsin Electric Railway Company, Oshkosh, Wis.—to build an electric railway in Oshkosh, and an interurban road between Oshkosh and Kaukauna. Capital stock, $1,000,000. Incorporators: T. E. Ryan, of Waukesha, and M. L. Campbell and W. F. Gruenwald, of Oshkosh. James K. Tillotson, of Toledo, was the promoter of the enterprise.

The People's Traction Company, New York—to build and operate about twenty miles of electric railways in the Annexed District. Capital stock, $1,500,000. Incorporators: Franklin A. Wilcox, Edward Hobbs, John A. Bensal, New York; Martin J. Keogh, of New Rochelle; Edward Hassett, Charles Mobbs, Brooklyn; John Foley, of Sewaren, N.J.; Eugene G. Blackford, Clarence Seamens and a number of other well-known business men.

The Clintonville Electric Light and Power Company, Clintonville, Wis.—to operate an electric light and power plant at Clintonville. Capital stock, $8,000. Promoters, D. S. Stewart, L. M. Stewart, Clintonville; P. A. Stewart, Morris, Wis.

The Suburban Telegraph Company—to operate a line between Westchester villages, New York and Brooklyn. Capital stock, $10,000. Incorporators: William Bryant, James McCullom, T. P. Tighe, Michael McGonigle and George E. Shepherd.

The Ballston Electric Railroad Company—to operate an electric street railway for passengers, express and freight for a distance of ten miles from Ballston Spa to Middle Grove or Jamesville, in the town of Greenfield, N. Y. Capital stock, $200,000. Directors: Thos. Craig and Robert J. Brace, Trenton, N. J.; Charles E. W. Smith, Roland F. Hill, of New York City; J. H. Burke, F. R. Barnes, Thomas Kerley, of Balston Spa; John Leggett and Joseph A. Leggett, of Troy.

The Seneca Light and Power Company, Seneca Falls, N. Y. Capital stock, $100,000. Directors: A. C. Mercer, C. T. Silsby, N. T. Wilcox, J. W. Hammond, of Seneca Falls, and P. M. Kendig, of Waterloo, N. Y.

The Guest-Bates Marine Life Saving Appliance Company, Hoboken, N. J.—to manufacture and sell all kinds of marine life-saving apparatus and especially the electric lighting thereof, etc. Capital stock, $100,000. Promoters: Jas. A. Guest, Edward C. Chew, Washington, D. C.; Jas. H. Bates, Hoboken, N. J.; Chas. J. Bates, Englewood, N. J.

The Oakland Railway Company, Royal Oak, Mich.—to prosecute a general railway business. Capital stock, $50,000. Promoters: Geo. Hendrie, Strathearn Henrie, Crosse Pointe, Mich.; Jno. C. Donnelly, Detroit.

Woven Wire Brushes.

The Belknap Motor Company of Portland, Me., are the patentees and manufacturers of the best Woven Wire Brush on the market.—[*Adv.*

ELECTRICAL PATENT RECORD.

LETTERS PATENT ISSUED JANUARY 29, 1895

ELECTRIC RAILROADS AND APPLIANCES.

533,154. Circuit-Closer for Railway-Rails. Edgar C. Wiley, Bristol, Tenn., assignor to the Wiley Railway Electric Signal Company, same place. Filed May 29, 1894.

533,259. Electric Locomotive. S. Lloyd Wiegand, Philadelphia, Pa. Filed Oct. 23, 1890.

533,261. Bonding Device for Electric Railways. John J. Zimmele and Antoine Bournonville, Philadelphia, Pa.; said Bournonville assignor to said Zimmele. Filed Nov. 30, 1894.

ELECTRIC LIGHTS AND APPLIANCES.

533,100. Electric-Arc Lamp. Hans Swoboda, New York, N. Y., assignor to the General Incandescent Arc Light Company, of New York. Filed March 2, 1894.

533,196. Combined Portable Stand and Wall-Bracket for Incandescent Electric Lamps. Herman Horn, Philadelphia, Pa. Filed Feb. 15, 1892. Renewed June 29, 1894.

533,211. Electric-Arc Lamp. Eugen Conrady, Keighley, England. Filed Dec. 16, 1893.

533,223. Incandescent Electric Lamp. George R. Lean, Cleveland, Ohio. Filed Nov. 29, 1893.

DYNAMOS, MOTORS, ETC.

533,083. System of and Apparatus for Controlling Electric Circuits. William B. Potter, Lynn, assignor to the General Electric Company, Boston, Mass. Filed July 24, 1893.

533,084. Rectifying-Commutator and Method of Making Same. Henry G. Reist, Schenectady, N. Y., assignor to the Thomson-Houston Electric Company, Boston, Mass. Filed Oct. 19, 1894.

533,108. Electric Motor. Charles Wirt, Chicago, Ill. Filed April 23, 1894.

533,146. Apparatus for Smoothing Currents of Dynamo-Electric Machines. Charles E. Scribner, Chicago, Ill., assignor to the Western Electric Company, same place. Filed Jan. 16, 1892.

533,244. System of Distribution by Alternating Currents. Charles P. Steinmetz, Schenectady, N. Y., assignor to the General Electric Company, of New York. Filed April 2, 1894.

533,245. System of Electrical Distribution. Charles P. Steinmetz, Schenectady, N. Y., assignor to the General Electric Company of New York. Filed April 13, 1894.

533,246. Winding for Dynamo-Electric Machines. Charles P. Steinmetz, Schenectady, N. Y., assignor to the General Electric Company, of New York. Filed July 14, 1894.

533,248. System of Electrical Distribution. Charles P. Steinmetz, Schenectady, N. Y., assignor to the Thomson-Houston Electric Company, Boston, Mass. Filed Sept. 24, 1894.

533,318. Controller or Switch for Electric Motors. William J. Pohlman, Woodbrook, assignor of one-half to J. Edgar Orrison, Baltimore, Md. Filed Nov. 17, 1894.

533,323. System for and Method of Electrical Distribution of Energy. William Stanley, Pittsfield, Mass., assignor to the Stanley Laboratory Company, same place. Filed Nov. 3, 1894.

533,378. System of Electrical Distribution. Charles P. Steinmetz, Schenectady, N. Y., assignor to the General Electric Company, of New York. Filed April 5, 1894.

533,379. System of Electrical Distribution. Charles P. Steinmetz, Schenectady, N.Y., assignor to the General Electric Company of New York. Filed April 11, 1894. Renewed Dec. 24, 1894.

BATTERIES.

533.078. Primary Battery. Richard O'Toole, Mechanicstown, assignor of one-half to George W. Smith, Baltimore, Md. Filed Aug. 3, 1893.

TELEPHONE AND TELEGRAPH APPARATUS.

533,142. Telephone System. John I. Sabin and William Hampton, San Francisco, Cal.; said Hampton assignor of one-fourth of the whole right to said Sabin. Filed April 14, 1894.

533,147. Telephone-Switchboard Apparatus. Charles E. Scribner, Chicago, Ill. assignor to the Western Electric Company, same place. Filed May 13, 1892.

533,148. Spring-Jack for Telephone-Switchboards. Chas. E. Scribner, Chicago, Ill., assignor to the Western Electric Company, same place. Filed May 23, 1892.

533,254 Signaling-Telegraph. Frank A. Turner, Chelsea, Mass., assignor to the Gamewell Fire-Alarm Telegraph Company, New York, N. Y. Filed July 27, 1893.

MEASURING INSTRUMENTS.

533,107. Electrical Measuring-Instrument. Edward Weston, Newark, N. J. Filed March 11, 1891.

533,269. Recording Ampere Meter. William H. Bristol, Hoboken, N. J. Filed July 26, 1894.

533,270. Electrical Measuring-Instrument. William H. Bristol, Hoboken, N. J. Filed Sept. 24, 1894.

MISCELLANEOUS.

533,130. Combined Curb, Gutter and Conduit for Electrical Conductors. William Kingsley, St. Paul, Minn. Filed Feb. 1, 1893. Renewed Nov. 15, 1894.

533.183. Automatic Electric Signal. Henry C. Stores, Hartford, Conn., assignor of one-half to Edward R. Faxon, same place. Filed April 20, 1894.

533,398. Automatic Electric Safety System for Railroads. Rene R. Snowden and Albert C. Ives, Ocala, Fla. Filed Jan. 26, 1894.

ELECTRICITY.

·Vol. VIII. NEW YORK, FEBRUARY 13, 1895. No. 5

ELECTRICITY

Published every Wednesday by the

ELECTRICITY NEWSPAPER CO.

B. E. GREENE, Pres't. L. J. MONTGOMERY, Sec'y.

PUBLICATION OFFICE:

6 Park Place - New York

EDITORS: NELSON W. PERRY.
BURTON E. GREENE.
R. H. WILLOUGHBY.

SUBSCRIPTION RATES:

United States, - - - - $2.50
In Clubs of Five or More, - - - - - $2.00
Foreign Countries, - - - - - - $4.50
Single Copies, - - - - - - 10 Cents

ADVERTISING RATES:

As Electricity reaches all classes interested in electrical work, its value as an advertising medium can be readily appreciated. Rates will be sent on application.

Changes for advertisements should reach the office not later than the Saturday preceding the date of publication.

Entered at the N. Y. Post Office as Mail Matter of The Second-Class.

TRADE SUPPLIED BY
THE AMERICAN NEWS COMPANY,
THE WESTERN NEWS COMPANY,
And their Agencies in all Principal Cities.

N. E. L. A.—The next annual meeting of the National Electric Light Association will be held at Cleveland, O., February 19-21, 1895. Every concern interested in either lighting or railway work should be represented in the membership of this body, and should have at least one representative at the Cleveland meeting. The Secretary is Mr. Geo. F. Porter, 136 Liberty street, New York.

EDITORIAL NOTES.

Researches Relating to Electro-Magnetic Oscillations. In another place we reproduce an editorial on this subject, from the London *Electrical Review* of January 25, which consists chiefly of a review of the work of Prof. Minchin on the conductivity of films of metallic powders, and the effects thereon of electro-magnetic oscillations. The results obtained recall to mind the investigation by Mr. Nelson W. Perry of the effect of electro-positive gases upon similar films, in which almost identical results were in many cases obtained.

Mr. Perry published the results of his investigations in the issues of Electricity of December 16, December 23, and December 30, 1891, under the title, "Some Unexplained Electrical Phenomena." Mr. Perry's method consisted in breaking an electric circuit and then bridging over this break by thin films of non-conducting substances, such as pulverized glass, metallic powders, a thin film of shellac, etc., etc. Usually one or both terminals of the conductor were covered with these films, and then brought mechanically together, but not with sufficient pressure to destroy the insulating character of the film. Taking hydrogen gas as a type of electro-positive gases, he applied this, or an atmosphere containing it, to the junction, and obtained results so similar to those obtained by Prof. Minchin that if the word "hydrogen" be substituted for the expression "electro-magnetic field," the editorial in question would in many particulars apply equally well to Mr. Perry's work. He found that after subjecting this bridge for a considerable time to an atmosphere of hydrogen it became highly conducting, but returned to the non-conducting state again upon standing in pure air. The bridge had, however, undergone some change by this treatment, a change apparently exactly similar to that observed by Prof. Minchin; for it was now exceedingly sensitive to hydrogen gas, and would resume its conducting state almost instantaneously upon being subjected to an atmosphere containing as little as .1 per cent. of hydrogen. "In other words, once we have succeeded in driving a current through the metallic powder surface, it responds to very feeble electro-magnetic impulses, whereas it previously failed to respond to strong impulses," has its counterpart in Mr. Perry's article in this: "Such a tube having passed satisfactorily through the preliminary stage (viz., brought to the conductivity state by pure hydrogen and then allowed to go back to the non-conductivity state), which I designated as the process of 'forming,' would respond to the most minute traces of hydrogen. In an atmosphere containing less than one-tenth of one per cent., it would almost instantly change from a resistance so high that several Laclanche cells in series acting through it would fail to show the slightest current on an ordinary galvanometer, to one so low that the deviation of the needle did not perceptibly differ from that obtained when the instrument was not in circuit."

The editorial says: "Let its conductivity now be destroyed, and it will be found after this to respond very easily to the actions which previously produced no effect upon it." Mr. Perry noticed that with his instruments there was a sort of fatigue. They lost their sensitiveness to hydrogen after a large number (40 or 50) applications, and finally refused to respond even to pure hydrogen. He tried a very large number of powders, and found them all to possess this peculiar property in a greater or less degree, but each one seemed to evince some characteristic peculiar to itself. He also studied the behavior of electrodes of different metals, with the same pulverulent material, and noticed some peculiar effects due to these. One of the most peculiar was that when one electrode was of copper and the other aluminium, and the pulverulent material the black oxide of palladium, the combination after having been sensitized or "formed" showed marked æolotropic qualities. Such a combination would always conduct better in the direction in which the current was passing during the forming process, but the difference of conductivity in the two directions varied considerably in different instruments. In some it would conduct *very* well in one direction, while in the opposite it would not pass sufficient current to give any indication on an ordinary galvanometer. This æolotropism also showed fatigue, for it gradually disappeared on repeated reversals of current.

Mr. Perry's phenomena and those described by Prof. Minchin, while very similar in many respects, cannot both be due to the same cause, unless it be to some as yet not understood property of films. Mr. Perry offers no explanation of his results, since no theory that he has advanced seems adequate. In looking for an explanation, he adopted the method of exclusion, and thus one by one his various hypotheses have been abandoned. It would seem that this subject of the electrical behavior of films offers a wide field for research and study.

* * *

The "Progressive Age" and the Welsbach Light.

Our esteemed contemporary, the *Progressive Age*, in its issue of February 1, in replying to a recent editorial in these columns, says: "We decline to continue further in a discussion which is rapidly degenerating into a battle of words more or less sarcastic and bitter." We are not surprised at this announcement for it is the usual refuge of those who, in endeavoring to sustain an argument, have the very ground upon which they stand knocked from under them. It goes on to say: "If there be a kernel to the attack it makes upon us, it is the statement that we make 'absolutely no reply to our (Electricity's) arguments against the Welsbach light.'"

Now our contemporary seems to be laboring under a false impression, which we desire to remove, viz., that our attack has been directed against itself. Nothing has been further from our thoughts than an attack upon such an excellent publication as the *Progressive Age*. Our attack, if such it can be called, has been against the Welsbach light purely and solely. The *Progressive Age*, which seems to be the official organ of the Welsbach, undertook to laud the new light to the skies. So little attention was paid to what it had to say on this subject that it began to take itself seriously, and finally in a leader expressed surprise that its statements had up to that time gone unchallenged. We were at that time looking into the merits of the Welsbach light, and in our issue for November 28 published the first of our editorial comments upon it. We intended to be fair, and gave the truth as we saw it then, and have seen no reasons since to change our opinion. In this editorial we made no reference whatever to the *Progressive Age*.

On December 1 it published the testimony of Profs. Renk and Bunté and Dr. Kruger, and upon this we commented in our issue of December 12 in a way that displeases our contemporary. It says: "We do not recognize any arguments." Well, what can be done with a person who will not recognize arguments? It goes on: "We published the tests of Profs. Renk and Bunté, men of such standing that to criticise their technical methods in the case in point would be presumptuous on the part of any journal." Well, now, if these men are such high authorities that it is presumptuous to criticise them, what is our contemporary going to say when these authorities criticise one another? That is practically what they do. The statements of any one of the three *may* be true, but if the statements of any *one* of the three *are* true, the statements of the other two, or some of their statements, *must* be false.

Our contemporary by publishing these statements puts itself between the two horns of a dilemma, and our *presumption* consists simply in pointing out to our contemporary that the tips of these horns are both equally sharp. It evidently sees that this is true and says, "I won't sit between the two horns because it is dangerous. I won't sit on either one of them because it would hurt. I have been using the Welsbach light until I am blind, and I don't see any horns, and I won't play anyway. So there, now!"

In its last issue it devotes two columns to a report, copied from the London *Lancet*, on incandescent gas lighting, which it fondly imagines settles all the vital questions except that of the expense and trouble attending the light which it champions. It is evidently a firm believer in the adage that "figures won't lie," forgetting that other equally credible assertion that on certain occasions "liars will figure."

Had we not learned from the publication of the testimony of Profs. Renk, Bunté and Dr. Kruger that our contemporary's judgment as to what constitutes good argument to its cause was fallible, we should have expected it to see how shallow, and in some cases erroneous, the conclusions of the *Lancet* report are. As it is, we are not surprised that it publishes it without comment. For the benefit of the *Progressive Age* and our other readers, however, we reprint in this issue the comments of our London contemporary, the *Electrical Review*, on this report, which show how valueless some of its claims are.

The *Progressive Age*, referring to this report, says:

"The further scientific testimony which we publish in this issue is cumulative." [Yes, cumulative.—Ed.] "As these authorities are *also* beyond impeachment by Electricity, . . . it is evident that conviction on our contemporary's part is impossible. We therefore beg to drop the subject."

Our contemporary is again wrong in stating that "conviction" on our part is impossible. On the contrary, the conviction is very rapidly growing that our contemporary made a very poor defence of the Welsbach light. Poor as the light is as a competitor of electricity, it is capable and deserving of a better defence than it has received. Its well wishers should try to save it from its friends, for they, in this instance at least, are doing it more harm than could be credited to its most bitter enemy.

Under the Searchlight.

Views and Opinions on Timely Topics.

All Ready for the Convention.

The management of the Hollenden Hotel at Cleveland have made thorough preparation for the comfort of their guests next week.

A large basement has been newly painted, brilliantly lighted, and fitted for the use of exhibitors.

Owing to the increased liability to illness at Convention times, it is proper to announce that Dr. Charles Betzler, the resident physician of the house, has no superior in his line, and that he can prescribe sure cures in four doses for almost every known ailment. He is an expert in the cure of melancholia.

* * *

THE ROLL OF HONOR.

What it Means if Correct.

There are at present four weekly electrical journals in this country other than the *Electrical World*. In order of age they are the *Electrical Review*, the *Western Electrician*, the *Electrical Engineer* and Electricity. Each has, in its own way, contributed important service in the interests of the development of the art and of the commercial side of the business. Each has a respectable constituency, and is conducted by respectable men. Each is to-day supplying to the workers in the field something which they want. Each has thousands of warm friends. These are truisms.

A few weeks ago Mr. W. J. Johnston issued a pamphlet containing what he termed a Roll of Honor—a list of concerns who advertise only in the *Electrical World*. It was inaccurate, containing many concerns who are regular patrons of other papers; but it contained the names of some concerns who do advertise only in that paper.

So far as we know, however, none of the firms has protested against the situation in which it is placed.

What is the full meaning of this publication? Plainly nothing else than that the companies appearing in this so-called roll of honor have allowed public notice to be served that they have no use for the four papers mentioned above, nor for the men connected with them.

Is it supposed that the publishers and advertising solicitors of these four papers are angels or saints? Are they not just like other men, peaceable when possible, but ready to resent an insult of this nature?

Laying aside the direct value of advertising in the *Electrical Review*, the *Western Electrician*, the *Electrical Engineer* and Electricity, is it good policy to allow an insult of this nature to pass without protest?

* * *

F. W. Horne, of Chicago, was appointed receiver of the Fort Clark Street Railway Company at Peoria, January 24, 1895, representing the Street Railway and Illuminating Properties of Boston. $175,000 stock held by the General Electric Company has gone to find McGinty.

* * *

Brother Johnston says each copy of his paper costs him two cents more than the subscription price. On this basis his weekly loss on 2,500 paid subscribers is $50 plus the loss from those who do not actually pay.

* * *

Every company placing business with the *Electrical World*, after the developments of the last few weeks, offers direct encouragement to methods which would disgrace a Baxter street clothing man.

London Notes.

(From our London Correspondent.)

AN IMPORTANT LONDON INSTALLATION.

Among the first buildings connected to the supply mains of the City of London Electric Lighting Company were the Guildhall Banqueting Hall and the Council Chamber where the governing body of the metropolis meets every week. From time to time the original installation has been added to by the wiring of the Museum, Art Gallery and other premises connected with the Guildhall, so that at the present time there are more electric lights in regular use here than in any other set of buildings in London.

The total number of lamps now fitted is about 1,650, some of these being of 8, 16, 25, 32, 50 and 100 candle power. The total candle power of current consumed when all the lights are on is equal to nearly 25,000.

The following are some details regarding this installation: In the Banqueting Hall there are 14 fittings with 36 lamps of 16 C.P. each. These fittings were designed by Sir Horace Jones. Each is controlled by two switches to turn on alternate lights. The galleries of the hall are lighted by 24 lamps on brackets and pendants. The lighting of the roof of the hall is somewhat novel. It is effected by means of eight 100 C.P. lamps fitted in inverted shades, designed to throw out the beautiful lines of the Gothic roof.

In the Council Chamber, however, is found the chief feature of the whole installation. From the center of the chamber hangs a magnificent bronze electrolier, about 13 feet in diameter. This was formerly used for gas lighting, but it is now arranged with 60 25 C.P. and 18 16 C.P. lamps controlled in sections by 6 switches. On either side of the Lord Mayor's chair there is a standard carrying 9 lights, while looking down upon this chair is another standard carrying 9 lamps which light the press gallery. The corridor around this exquisitely furnished Council Chamber is lighted by 12 pendants. The light has a very brilliant effect upon the variety of colors used in this chamber, and shows up well the pieces of statuary and the gorgeousness of metropolitan officialdom.

The Art Gallery is lighted by means of 2 15-light electroliers and 40 pendants of 50 C.P. each enclosed in cut glass globes. This lighting is so arranged that in no case does the glare from the lamps fall on the varnished surfaces of the pictures.

The Library is lighted by means of 14 3-light pendants (32 C. P. lamps), 56 brackets (16 C. P. lamps), and 120 8 C. P. lamps on special 6 light pendants.

The Museum is lighted by means of 36 3-light bronzed brackets and 50 pendants.

In addition to the above there are nearly 600 lamps arranged on handsome fittings in the various committee rooms, public courts, etc.

The main switchboard is a splendid piece of work, carrying 6 3-pole circuits, 2 armatures and 1 voltmeter to read in each parallel. The current supplied is alternating. The whole of the wiring is carried out on the 3-wire system, viz., 6 (3 pole) circuits from main board to 3-pole branch distributing boards, and then distributed on the parallel system to the fittings, etc. The work has been very creditably carried out by the firm of Lund Bros. & Co. under the supervision of the consulting engineer, Mr. W. H. Preece.

Sight to the Blind.

D. A. Reardon, the superintendent of the printing office in the Perkins School for the Blind in South Boston, has almost perfected an apparatus by whose use the blind can actually see.

Light from Noise.

If that be possible, how much light we ought to have! There is an old saying that "talk is cheap." Will the alleged discovery detailed below extend the meaning of this saying so that it will read "light is cheap?" But if the quality of the light thus produced is of the same character as the talk that is cheap it is probably worse even than the Welsbach light.

According to an Associated Press despatch that is going the rounds of the papers, a convict at the Ohio State Penitentiary has invented a battery that needs only some one to talk to it to set it into action. We do not know whether or not the sending of this despatch around to the editors of the various daily papers was intended as a reflection on the talking abilities of the average reporter, but it looks very much that way. We notice that among the claims made for this acoustic battery is one that by its use a clock might be made to wind itself by its own tick. Now there is nothing so very remarkable about that, but if it could be arranged so that a man could clear up his indebtedness to his butcher or tailor by the tick which the latter had given him, the invention would be one of real and lasting utility. The acoustic battery is described as follows:

"If two dissimilar conductors of electricity which are subject to slight atomic change under the influence of sound are joined together after the manner of a pair of thermopile bars, and the open ends are insulated by a suitable non-conductor of both sound and electricity, a current is generated when sounds are made in the vicinity of the exposed ends. If two or more such elements are connected together we have an acoustic battery, and by increasing the number of elements it is possible to operate an ordinary call bell by simply clapping the hands in front of the exposed ends of the battery."

Thus it would seem to be a device working on a principle very similar to that of the thermo-electric pile, the sound vibrations being in this case substituted for the heat vibrations as a motive force. Levity aside, there is theoretically no absurdity in this, and it seems rather probable than otherwise that a battery capable of converting the energy of sound into electrical energy could be built acting on a principle entirely analagous to that to which thermo-electric currents are due. It will be remembered that Edison in the early days actually patented a device for accomplishing this same conversion, and it worked too, but was of no value whatever commercially. He constructed a huge tuning fork which was to be caused to vibrate in a magnetic field by resonance with its fundamental note sounded on another instrument, and still later Alexander Graham Bell invented the telephone, which is an adaptation of the same idea. The magneto receiver, when used as a transmitter, is a very familiar example of the facility with which sound may give rise to electric currents. The convict's idea, however, does not involve this principle. It would be a more direct method in which magnetism was not essential at all.

If this announcement is authentic, it is one of considerable interest. As a method of generating current for power or lighting purposes, however, it is of course highly absurd.

The Harrison Telephone Co. in the West.

Davenport, Ia., has granted a franchise for twenty years to the Harrison Telephone Company, under these conditions: The wires shall be carried on the poles already erected; the city shall have the use of the company's poles for fire-alarm and police lines; the city shall have use of ten telephones free of charge and the further right to purchase any number of telephones for its fire and police telegraph service at $30 for each telephone; the annual rental shall not exceed $30 per year for business houses or $20 for residences.

Researches Relating to Electro-magnetic Oscillations.

The question of employing impulsion cells, metallic films, and bodies of similar behavior, for detecting the nodes, &c., of electro-magnetic vibrations, has frequently been raised, and we are glad to see it engaging the attention of the Physical Society. Some time ago, Mr. Rollo Appleyard read at one of the meetings a paper describing the electrical properties of rods composed of metallic filings and gutta-percha, which we duly noticed. This has suggested to Prof. Minchin an inquiry into the behavior of certain bodies in the presence of electro-magnetic oscillations, the result of which appeared in a recent issue of the Physical Society. Prof. Minchin has made a few observations on films and metallic surfaces formed by embedding fine metallic powders in thin layers of gelatine, shellac, and sealing-wax, spread out upon plates of glass. Taking the case of sealing-wax, we find that although the prepared surface presents the appearance of a continuous metallic surface, yet when it is placed in circuit with a battery and galvanometer, it behaves as a non-conductor, so much so that if the electrodes connected with the surface are also connected with an electrometer it is found that the surface has an infinite resistance. Now if feeble electro-magnetic oscillations are produced in the neighborhood of the non-conducting surface, it will refuse to respond and remain a non-conductor. Let the field around it be greatly increased, however, or let one of the electrodes be actually touched by a charged body, and then the surface becomes a conductor. Let its conductivity now be destroyed, and it will be found after this to respond very easily to the actions which previously produced no effect upon it. In other words, once we have succeeded in driving a current through the metallic powder surface, it responds to very feeble electro-magnetic impulses, whereas it previously failed to respond to strong impulses. It appears that the behavior of the surface depends upon certain conditions, *e. g.*, in the case of gelatine, if this substance retains any plasticity, breaking of the contact is fatal to its conductivity, or if the substratum be hard, as in the case of sealing wax, and if strong electro-magnetic impulses have been communicated to it, the surface may remain a conductor for a long time, whilst if they have been small, it rapidly reverts to its non-conducting state. In his experiments, Prof. Minchin has observed the following constant relation:—If the surface is in the non-conducting state, and a feeble electro-magnetic field is produced around it, it becomes a conductor; but if, while it is conducting, a strong field is produced around it, its conductivity is destroyed. He thinks it possible that a law of this kind holds for all such bodies. The nature of the change produced in them depends either on the amplitude or on the frequencies of the incident impulses; but, in order to verify the relation, we should be able to deal with a film which from a definite state of non-conductiveness, changes always to a definite state of conductivity; and this, so far, has been impossible. So far this interesting subject has not been investigated very thoroughly, although in addition to these experiments and those of Mr. Appleyard, to which we have alluded, we have read of several described in papers recently communicated by Mons. Branly to the Academy of Science at Paris. The subject is particularly inviting, and, indeed, promising, since the establishment of laws having an important bearing may result from deeper investigation; and it is to be hoped that Prof. Minchin and others who have approached it will be able to see their way to carrying the matter through.—*The Electrical Review, London.*

THE ELECTROPOISE.

We Never Take A Dare.

The following communication speaks for itself, and since it would lose much of its force and beauty if modified in any way, we abstain from tampering with it and give it *verbatim et literatim et punctuatim.*

While the contribution is a gem as a whole, it is dotted here and there with those whose lustre makes them foci of rays of such scintillating beauty as to give added lustre to that which, even without them, would be of incomparable beauty. One of the brightest of these unmatchable gems is the inference broadly stated that the animus of our attack on the Electropoise is that we are in the same business, and that the Electropoise is making more cures than we are:

Phila. Feb. 5th 1895.

B. E. Greene, Prest.
Dear Sir

A pamphlet Book called Electricity, Published Dec. 12th, 1894, on Page 262 the Electropoise. Permit me to say I have an instrument called oxdoner victory Patented by Dr. Sanshe originally It was called Electropoise. permit me to say I am not an agent or interested In its magement In no way but I believe in fair play to every person and thing. of course this instrument may, and does make great inroads to your Electricity. Now if you are a fair business man you will publish this in your Book as you have published other communications, as follows; I James Coleman No. 1,727 Sydenham St., Phila., Pa., after the use of the oxdoner victory of nearly three years use proclaim It the greatest thing I ever struck. I have cured Every case of sickness that has came up in my family In a very short time some cases the doctor could not cure. I was a compleat wreck my self from Blood Poison and I cured my self. as your Book states many cases resulted in death. So does Death result under all circumstances. But I believe the oxdoner victory Is the greatest cure I Ever had the the privilege to have any Expearance with. I have known persons whom have tried Electricity and failed to be cured, But by the use of the Electropoise, now called Oxdoner victory. All your correspondence are perhaps not well posted in the use of Oxdoner victory commonly called (Electropoise) of course any sensible person getting one of these Instruments and using it according to instructions will never trouble your Electricity as a cure reccolect this is from a person that has had the constant use of this instrument for three years reccollect none of your correspondence claim to have made a use of them Now Mr. President dont condem a thing that has not been tried. I dont say there aint no Merit In your Electricity that would be wrong for me to do. So try and be fair to a good thing which I have found Oxdoner victory to be. It cost me $25.00 to get one and I know It has been the best investment I Ever made in my life. I never have to now call in a doctor It cures in a few hours Now Mr. Greene you are at liberty to publish this in your book. But I dont think you will, you aint fair enough to do that.

very Respectfully
James Coleman, 1,727 Sydenham St.,
Philada. Pa.

An Electro-Medical Fraud.

From the Western Christian Advocate.

Electricity, in its issue of November 21, prints an exposé of the "Electropoise," an extensively advertised panacea, with certificates of its effects from men in high places. It turns out, by scientific demonstration, to be the veriest cheat, achieving its magic healing through the imagination of its patrons. It claims to cure by "thermo-electric induction"—a conceit that has no scientific basis, there being no such thing known to electricians—to so polarize the body as to attract the oxygen to its surface and diffuse it through the system. The expert affirms that "neither magnetic nor electric polarization has any effect upon the atmosphere, except to abstract from it the dust; that, if the body were polarized to a million volts, there would be no such attraction," while this "little joker" has but "one-thousandth of a volt." The proprietor alleged that the closed cylinder contained two rare metals no chemist could analyze, while there are no metals which cannot be analyzed.

The exposé is scientific and thorough, and no candid mind can escape the conclusion that the device is devoid of merit, and that "the Electrolibration Company" is advisedly palming off on the afflicted a worthless nothing at an exorbitant cost to the purchaser.

The cheat ranks with the electric brushes, soles and "Perkins Tractors" exposed by Dr. Oliver Wendell Holmes.

As a psychological imposture on the infirmities of cultured minds it is the 'cutest fake of the age. We do our readers a practical service by forefending any tempted to try this costly fraud from losing their money and execrating themselves for their credulity.

Phosphorescence and Photographic Action.

A discourse on "Phosphorescence and Photographic Action at the Temperature of Boiling Liquid Air," was given by Prof. Dewar before the Royal Institution recently. The lecturer showed experiments to prove that bodies which at ordinary temperatures are very faintly, if at all, phosphorescent glow very brightly if, after being cooled to the temperature of boiling liquid air they are stimulated in the light of an electric lamp. Among the substances he experimented upon were cotton-wool, feathers, flowers, egg shells, quinine, acetic acid, and some of the complex platino-cyanides, the latter giving very brilliant effects. He proved experimentally that the stimulating power of the electric lamp lies chiefly, if not altogether, in its ultra-violet rays, and he showed the curious fact that the luminous and heat rays are able to dissipate the luminosity of a phosphorescing body in those parts upon which they have fallen. The latter part of the lecture was devoted to showing how greatly photographic action is diminished at exceedingly low temperatures—even to the extent of 80 per cent.

Economy of Electricity in the Scattered Distribution of Power.

The *Practical Engineer*, in an editorial on this subject, makes the statement that in using electricity as a means of conveying power, regard must always be had to the nature of the power which it is to replace. We are all familiar with shops of one sort and another in which from one or two sets of boilers there are steam pipes carried long distances and individual machines driven each by its own small engine. Now, it is not simply that small engines in themselves are so very wasteful; they rarely have the chance of showing what they can do with good dry steam, and they are rarely indicated to show what amount of fuel they are really consuming. It is, however, to the use in them of steam cooled by exposure in long lengths of pipe that a large proportion of their inefficiency is due. They are employed because steam pipes can be run easier than shafting, and once fixed require no attention, whereas a shaft calls for continual attention in oiling and maintenance. As between a high-class steam engine and short well-protected pipes, and an electric motor taking current from a distant dynamo, it is held that no one would doubt the superiority of the engine. But when the superior engine drives a dynamo, and current is led off to motors at a distance, there is no question but that this is superior to the use of small steam engines.

Can They Economize?

Mayor Blee of Cleveland is endeavoring to create a sentiment in favor of the city putting in an electric plant to light the city buildings.

At Harrisburg a bill has been introduced in the Legislature looking towards the establishment of a State plant for lighting the State buildings.

LEGAL NOTES.

In a suit for damages brought at Newark, N. J., by Sarah Goldberg, a brushmaker, against the Consolidated Traction Company, the amount sued for was fixed for her by an insurance expert at $10,188.86. The girl's hand was twisted and her thumb broken at the joint by a fall caused by the sudden starting of a trolley car she was in the act of getting on. The insurance man, with the aid of tables employed in his business, calculated the sum named as the exact amount at 4 per cent. required to recompense the plaintiff for her injury which, it was claimed, rendered her incapable of ever again working at the brushmaking business. The figures were based on the probability of the plaintiff's having thirty-nine years' producing power. The case is still before the courts, but it is doubtful whether they will consider the producing power of the girl destroyed for thirty-nine years by the loss of a thumb joint.

The deposition of Marcel Deprez, plaintiff in the case of Deprez against the Thomson-Houston Electric Company of Lynn, Mass., taken by United States Consul Frank E. Hyde, at Lyons, France, was filed a few days ago in the United States Circuit Court at Hartford, Conn., having been received by mail. The deposition was taken by Consul Hyde as commissioner, he having been appointed such by Judge Townsend, before whom the motion of the defendants for such deposition was argued. Marcel Deprez is a Frenchman, whose suit against the Thomson-Houston Company, originally brought October 10, 1892, is for an infringement of a patent on an improvement in the art of transmission of electric energy to a distance.

In the United States Circuit Court at Hartford, Conn., on the 4th inst. two bills of complaint were filed against E. S. Greeley & Co. of New Haven by the Western Electric Company of Chicago. The first alleges an infringement of a patented spring-jack switch, and the other alleges the infringement of patents on magnetic bells and telephone call boxes. An injunction and an accounting is prayed for in each case.

Judge Pennypecker has decided in a telegraph case at Philadelphia that the only damages recoverable for failure to deliver a cipher message as promptly as open messages are the telegraph company's charges for transmittal.

In the case of Lizzie A. Woeckner vs. The Erie Electric Motor Company, at Erie, Pa., the jury gave a verdict of $15,000. The little girl was run over by a street car and lost both legs in consequence.

Judge Arrington of the City Court of Montgomery, Ala., has appointed W. B. Rommee, receiver of the electric car line formerly known as the Seelye line. The appointment was made on application of the Westinghouse Electric Company and Wright & Lindsley, of New York, creditors. The operation of this road was suspended recently, but the receiver expects to commence running the cars again in a few days.

Utilization of Peat Bogs.

The peat bogs of Great Britain and Ireland are roughly estimated by P. F. Nursey at 6,000,000 acres, having an average depth of 12 feet, and being capable of yielding 3,500 tons of dried peat per acre. In Ireland there are 2,830,000 acres, or nearly one-seventh of the entire area of the island. More than half of the Irish peat is of the best quality, and, reckoned at one-sixth the value of coal, the total supply in Ireland is thought to be equivalent to 470,000,000 tons of coal. Here is a vast store of energy, points out J. Munro, which like the power of Niagara, may be converted into electricity and applied to many industries—especially those of manufacturing various possible products from the peat itself—in factories established near the bogs. Neighboring towns, moreover, could be lighted from the dismal moors, and railways worked.

THE FUTURE OF ELECTRICITY.*

BY SYDNEY F. WALKER.

Whenever one engages in conversation with anyone not in the ranks of electrical engineering, it rarely happens that one's friend does not remark very early in the conversation that "electricity is still in its infancy," usually prefacing the observation by the statement that he personally knows nothing of the subject. The observation has been made so often that one really becomes very tired of its incessant repetition, and we feel strongly inclined to beg our friends not to repeat the old saying too often. Yet after all, when we consider the question, is it not true in spite of what has been done during the last sixty years, and particularly during the last twenty?

Judged by the age of other branches of science electricity is still an infant, with all its manhood's work yet to accomplish—work that none who are now its servants can hope to take part in; work that few of us can even venture to foretell. It is by the use of steam and of electricity that the modern world of the nineteenth century is distinguished from the older worlds that have gone before. What might not those mighty races of bygone ages have accomplished had they been blessed with such servants as these? And even now, while steam is young, as the universe judges time, the handwriting is on the wall, not, as at the Eastern monarch's feast, in strong condemnation of the empire that is passing away—for steam has been a faithful servant, and will be for many years to come—but as a warning that its days are numbered, nevertheless. And may it not be also in the future that even the young giant we serve, whose infantile deeds are so prodigious, will have to give place to another agent as yet unknown? If it be that electricity and electro magnetism, with sound, light and heat, are merely varying forms of the same thing, varying rates of molecular motion, can we suppose that there are not other rates of motion possessed of other properties possibly still more wonderful than those that have surprised the present generation? Between the molecular motion we know as sound and the slowest of the motions we know as invisible heat, there is room for many other rates.

But what may we hope for in the future from electricity itself? First, then, the gradual utilization of the forces of nature known as wind and water power, to the gradual displacement of power from the combustion of coal. At irregular periods the world is startled by the cry, What will become of us when our coal fails? We are turning out an increasing number of millions of tons yearly, and the supply is limited. We are squandering our national wealth. What is to become of us as a manufacturing nation? Long before the supply of coal approaches exhaustion its price will increase and our other industries will be crippled. What are we to do? The reply is, in my opinion, that long before the price of coal rises from this cause coal itself will have to fight for its life as an industrial product, just as gas is now doing, the antagonists being wind and water power, delivered where required by the aid of electricity.

And what about gas? Only twelve months since it was safe to prophesy, as far as could be seen then, that gas was doomed to extinction at no distant period. The perfection and adoption of the Welsbach incandescent gas burner will probably give it a new lease. If the Welsbach apparatus becomes universally adopted, and the gas companies are able to carry out their threatened revolution, the supply of a heating gas only—necessarily a much cheaper gas—electricity will have received a very serious setback, the most serious it has received during the last twenty years. Once the price is reduced gas will be used much more for heating and for power than it is now, and while at present the running cost of an incandescent lamp is twice that of an ordinary gas burner in any district, and power costs four times as much when taken from any town's electric supply mains as it costs when taken from the gas service, the proportion when cheaper gas is supplied will be very much greater. But a little consideration will show that the setback will be only temporary, can be only temporary, unless electrical engineers alter very considerably during the next few years. The principle of the Welsbach burner, or its equivalent, must be adopted in the electric incandescent lamp of the future. In the Welsbach burner we have a substance capable of withstanding a high temperature with the necessary heat applied to the substance from outside by means of the combustion of gas. When electric lamp-makers find a substance that will stand very much higher temperatures than the present incandescent lamp filaments do, the Welsbach burner will again have to take a back seat, and electricity will have made another stride, and a very long one, in its progressive fight with its rivals, since in addition to reducing the running cost of the lamp itself, its greater efficiency will enormously increase the earning power of the plant and cables.

In the matter of power, too, the gradual education of consumers in the use of higher voltages will gradually decrease the running cost. There is one use of electric power, however, for which the present outlook does not seem very hopeful, viz., for tramcar driving.

Notwithstanding all that has been done in America, and the special cases in this country where electricity has been successfully employed, apparently it must be some years, many years, before it can be generally applied to the ordinary street service, unless some unforeseen discovery should be made very shortly. America is not England, and the Black Country is not England; and no matter what may be tolerated there, no English town of importance would be likely to allow the hideous arrangements necessary for the overhead system in any of its principal thoroughfares. The conduit system and the accumulator system await the march of invention. Both are barred by the excessive cost of running.

Heating by electricity, though only recently introduced, has already made rapid strides; and although where the current to be used for heating is taken from the town supply the cost is still so excessive that it can only be regarded as a luxury, yet there are now many cases where the extra convenience is well worth the extra cost, and there will be many more as time goes on, and as the natural development of the lighting industry produces the usual effect, viz., gradual reduction of cost.

Telephones are daily becoming more and more used, and hence more and more useful. The future for them should mean still further usefulness by reason of more perfect service. In the future, too, we may hope to have communications by telephone without wires. Shall we also see by electricity without wires? In mining and general industrial work the progress of electricity in the past and the hopes for the future leave nothing to be desired.

Whether Messrs. Thwaite and Swinburne's idea of burning the coal and the gas generated in coal mines at the pit's mouth, and distributing to centers of industry, is ever realized will depend on how soon the developments of wind and water power are made. Possibly some such scheme may come in to assist coal in its battle, in the same way that the Welsbach burner has come in to assist gas now.

Local conditions, too, will largely rule whether coal, wind, or water shall be used, since the initial outlay will be approximately the same, and the voltages used may be the same. But, since for both the economical consumption of coal at large centers and the utilization of wind and water power, high voltages will be necessary, and the higher the voltage that can be employed the more economical will be the working of the system, may not engineers indulge in a yet bolder dream?

The dream of ages, the utilization of the gigantic energy of Niagara, is now, in part at least, an accomplished fact; is it too bold to dream of using the energy of the agent that creates Niagara, the sun itself, by the aid of electricity, to neutralize some of the effects created by the absence of the sun's rays? Daily, hourly, the whole year round, enormous quantities of energy are delivered directly to the earth within the tropical zone, yet during the whole year large tracts of land are rendered absolutely valueless to man owing to the want of the heat so abundant in the tropics, while even yet larger tracts are deprived of a considerable part of their fertility from the same cause. Is it too bold a dream to imagine a portion of the superfluous heat of the tropics delivered within the icebound regions by the aid of electricity? What would our ancestors have thought if anyone had foretold in their days the present use of Niagara?

Once more, too, if what we know as electricity be a form of molecular motion at a lower rate than the slowest of the invisible heat waves, the day on which it becomes possible to reduce the rate of the molecules, when vibrating under the influence of heat, directly until their motion corresponds with the rate we know as electricity without the at present necessary repeated transformations, an enormous stride will have been made towards neutralizing the inequalities of climates on our globe. And there is even yet another manner in which we may hope that electricity may help us in our battle with the inequalities of nature.

It is now some years since Lord Rayleigh discovered that the large raindrops we are so familiar with in thunder showers are due to electrification, and consequent aggregation, of the fine particles of moisture present in the atmosphere. It is also some years since Prof. Oliver Lodge added to Lord Rayleigh's work the discovery that floating dust particles might be aggregated in the same manner as the raindrops are by discharges of static electricity. Yet beyond an apparently crude experiment on lead dust, no use has been made of either of these brilliant discoveries.

Is it too bold, wickedly bold, to hope that in the future, by means of electricity, we may be able, at least in part, to control our seasons? Why need we have a dry summer, as in 1893, when the moisture is present in the atmosphere, and can be made to descend? Why need we have superlatively wet seasons if the atmosphere is not allowed to retain a superabundance of moisture, when it may be caused to discharge its cargo when desired? Why should not our Government vote a large sum to working out these problems? Can we doubt that if the discoveries had been made by French physicists the French Government would not have given every assistance, instead of standing coldly by, supremely indifferent until the time arrived when the discovery may bear taking? Is it too much to hope that the coming year may see some little thing done in this direction?

---

* "The Electrical Engineer" (London).

A French railway has recently arranged its telegraph lines so that at a prearranged signal the wires are switched from the telegraph instruments to telephones, thus enabling the operators either to talk verbally or to communicate by the telegraphic code at will.

Low Rail Joints of Street Railways and Their Prevention.

BY N. S. AMSTUTZ.

Recent conditions of street railroad traffic have developed one thing above all others needing careful attention, viz., poor rail joints. With the old equipments, the rail joints were able to withstand the traffic much longer than very heavy rails do under the impositions of recent traffic requirements.

The horse car traveled slowly, its weight was but little compared to the modern "motor," and in consequence where a low joint existed the trouble was not aggravated to the same extent as it now is. Then the change from good to bad was so gradual that the patronizing public made small note of it. Now the changes are so rapid that they cry out against them, and the loudness of the complaints keeps pace with the speed of the vehicles of transit.

A difference of level between the adjoining ends of rails, that under the old regime was negligible, under the new is of the gravest importance. This is not due alone to the heavier equipments used, but also to the greater speeds at which the cars are run. The blows at slower speeds, as the car wheel dropped but a thirty-secondth of an inch from one rail to another were but "tack hammer" forces in contrast with the "steam hammer" effects produced by the heavy motors of to-day at their higher speeds.

The steam railroad does not have the same conditions to contend with, since the rails themselves are not imbedded in the earth, as street railway rails invariably are where the track is laid in a public highway.

The street-railway practice makes possible the most disastrous combination of circumstances, which becomes a constant drain upon the resources of t.e tramway company. These causes are chiefly due to—

1st. Allowing water to accumulate at a rail joint between the rails and the paving or the adjacent earth during rainy weather. This implies the retention of water at a rail joint after the rest of the street is comparatively dry.

2d. Joints becoming loose.

3d. Allowing loose joints to remain so until the rails have a decided "set" downward at each end. This usually follows when the joints occur between ties.

4th. Allowing the puddling chambers at joints to exist whereby the tamping under the adjoining ties is removed, and the most favorable conditions are created for producing "set" rails.

5th. Allowing the differences in level between rail ends to continue to exist, wherein seems to lie the prime cause of most all of the street railway track ailments.

In the construction of new track it is almost impossible to get perfect alignment even though the rails are all rolled from the same rolls. Where the rails are placed in position at once after being received from the mills, there is not so much liability of a difference existing in the levels of their tread portions, but if they are allowed to lie along the roadway in all kinds of weather, some ends exposed more than others, it certainly would seem as though the absolute sameness of cross section at the ends would be destroyed, because of the scale formations, etc.

When rails are laid with an expansion space between their ends, the plans herein outlined would not be so efficacious, but with rails laid without the expansion space, which recent experiences with welded rails seem to show is not necessary, the proposed remedies would, I believe, be specially pertinent.

Just as surely as a difference of $\frac{1}{64}$ inch exists between the levels of adjoining rail ends, so surely will the heavy motors find this difference and aggravate it.

If the weight of the car comprised only pig iron, then the disastrous results would bear heavily only upon the tracks, but unfortunately the greater portion of its weight is made up of electrical machinery, worthy of better treatment.

The ultimate effects of hammering on single track roads would not be so great as in double track systems, where the traffic is all in one direction; but when it is considered that under a 5-minute headway an aggregate of 840 blows per week are delivered by a car operating ten hours a day, each succeeding blow being slightly heavier because of the increase of drop which is constantly produced, the seriousness of this influence will be appreciated. Even with the heavier rails and "channel" fish-plates which are now being used, the damage due to this cause is not entirely removed. It is therefore of the utmost importance that a preventive should be used, so as to insure the maintenance of the best possible conditions for the preservation of the track and the car equipments.

Directly along this line I would propose the following procedure for old as well as new track. These deductions are based upon a number of years of careful observation of the older horse car and the more recent electric track constructions.

For old tracks, it would be most expedient to—

1st. Carefully inspect the track, and locate all the loose joints.

2d. Re-tamp the ties located adjacent to a low joint.

3d. Cement or otherwise fill in the space which exists between the web of the rail and the paving up to and beyond the adjacent ties. This would prevent accumulation of water, and in a great measure be beneficial in preventing the open spaces between the ties and the earth beneath, which are formed by constant vibration when water is present.

4th. Carefully surface up the rail ends where they meet, in the manner hereafter described.

With new tracks the plan proposed would be somewhat as follows, viz.:

a. Using the new track for at least a day before the track is finally aligned.

b. After the day's use, re-tamp the ties, and finally align the track.

c. Surface the rails before paving.

d. Cement the spaces under the rail head, as set forth in the division (No. 3) preceding.

e. Re-surface the rail joints after one or two weeks' use.

f. After a few months inspect the track with the indicator to locate defective joints.

The maintenance of a repaired or new track is much the same, and it is a case where eternal vigilance becomes the price of good track. All the troubles recounted can usually be traced to a a slight inequality of the rail ends.

A slight drop sets the rails into vibration, and if the process is continued for a time, the fish-plates will surely become loose at one end or the other, and then the matter goes from bad to worse until both ends are loose, when it is but a question of a short time when the rails will be "set" and the track almost irreparably ruined.

Numerous attempts have been made to re-align old tracks having "set" rails therein, but the result has invariably been unsatisfactory. No amount of doctoring short of straightening the rail (which is impracticable) will remedy the matter. The old adage, "An ounce of prevention is worth a pound of cure," is certainly as true when applied to street railway track preservation as elsewhere.

The watchword of the day is *prevention;* this is the key to the present propositions, in that the conditions which make possible all the ills to which a street railway track is subject might be eliminated by timely preventive measures far more easily than they can be cured after having once come into existence.

The surfacing car which I would propose for the purpose may be described as follows:

It may consist of an ordinary truck with a special housing built thereon, with tool box conveniently placed at each end, on the outside, so as to be easy of access. It should have suitable couplers, and a single motor connected to the front axle with an ordinary car controller directly in front and a brake located within easy access. A lamp should be placed under each canopy, and a cluster of three lamps placed on the inside. The surfacing mechanism is made in two units, one on each side of the car, so as to serve both rails simultaneously if necessary.

This mechanism may be described as follows: It consists of a rapidly rotating emery grinder having bearing at the end of the short arm of a bell crank lever; the long arm carries a pivoted nut which is moved laterally by a worm shaft, having one or two hand wheels thereon; the worm shaft is supported upon a suitable frame which rests on the car floor. The lever is fulcrumed at the "knee" in a hanger secured beneath the car floor, and the emery grinder is connected to a stationary motor by a flexible shaft in any suitable manner.

If desired, the flexible shaft could be connected to a counter shaft through the medium of a clutch; this latter arrangement in some respects would be preferable, because either of the grinders could then be disconnected at pleasure without affecting the other one. The usual starting box, etc., would be provided for the stationary motor.

The operator is enabled to see the progress of the work through a slot in the car floor, and the speed of travel could be as fast as the special requirements would call for.

In order that the surfacing might be done at night time, so as not to interfere with the ordinary day traffic, lamps are hung under the car floor, near the grinders, in suitable protecting guards. The reflection on the cleanly ground surfaces of the rails would very readily indicate the progress of the work.

A very little grinding at each joint will suffice, and this can be repeated as occasions demand.

The "grinding car" would be of special importance in surfacing down new work, such as switches, cross-overs, etc.

In addition to the surfacing or grinding car, I would also propose a mechanical track inspector, on the plan described below. This could be drawn over the track by an ordinary motor or the surfacing car. Its function would be to automatically indicate the location of low or defective rail joints, so that they might be repaired as early as possible. This car consists of a four-wheeled truck with any suitable frame, provided with two indicating wheels mounted upon the same axle. The bearings of this axle are free to slide up and down in the central housings, as the inequalities of the track are passed over, while the end axle bearings are held rigidly upon the truck frame.

The central axle bearings have connected therewith a bell crank lever which has its fulcrum pivoted on the central bearing housing, and its longer arm is connected by a link to a sliding valve. This valve regulates the flow of any coloring matter which is contained in a tank placed for the purpose on the truck. Two spouts lead from the tank, one on each side of the truck, terminating so as to deliver the coloring matter as near the rail joints as deemed desirable.

The action of the device is as follows: When either one of the central wheels passes over a low joint it moves downward in relation to the truck frame; this moves the belt crank lever, and opens the valve in the spout and allows the color to discharge upon the paving or the ground, or the rail if this be thought best.

As soon as the central wheel moves from off the low portion of the track, the valve is closed.

If the coloring matter in the tank is in liquid form, the valve should simply be perforated. If in the form of powder, the opening should be ample to guard against clogging.

The valve can be actuated as delicately as desired by changing the link connection to the bell crank lever.

Results of the Elihu Thomson Competition.

The Elihu Thomson electrical energy meter, having obtained at the meter competition organized by the city of Paris a first prize of 5,000 francs, Prof. Elihu Thomson generously devoted this sum to facilitating the study of certain theoretical questions of great interest.

This competition is now ended, but before stating the conclusions of the jury we will give a brief sketch of the history of the competition. Towards the end of the year 1889, the city of Paris organized a competition of electrical meters, and placed at the disposal of the jury a sum of 20,000 francs to be given in prizes. But the result of the little time allowed the competitors in which to submit their instruments was that very few meters were sent in and none of them entirely satisfied the conditions of the programme.

Nevertheless, at the request of the jury, a sum of 7,000 francs was distributed in prizes of encouragement, and a second competition was organized.

The conditions of this second competition were as follows:

Article 1.—A competition is open to all inventors of electrical meters that can be applied either to continuous currents alone, to alternating currents alone, or to both forms simultaneously.

Article 2.—The meters submitted may be either electricity meters (ampere-hour meters) or energy meters (watt-hour-meters).

Article 3.—The readings of the meter must be direct and the consumer must be in a position to ascertain for himself the quantities consumed.

Article 4.—The meters must be suited to small consumptions; the electricity meters must register from $\frac{3}{10}$ths of an ampere, and the energy meters from 20 watts.

Article 5.—The meters, together with an explanatory note, must be deposited in a sealed package, at the Halles Municipal Station, from the 25th to the 31st of August, 1890, without fail. A receipt will be given for them.

Article 6.—The meters will be submitted to a committee consisting of nine members, five of whom will be appointed by the Municipal Council and four by the Administration.

Article 7.—The instruments will be subjected to comparative experiments bearing upon:

(*a*) Their accuracy throughout the scale of outputs that they are capable of recording.

(*b*) Their practical value (regularity, simplicity, cost, etc.)

(*c*) The energy expended in their working.

(*d*) The amount of trouble entailed by their employment in the distribution of current.

Article 8.—A sum of 13,000 francs will be distributed in prizes under the following conditions:

10,000 francs to the inventor who will produce a meter giving every satisfaction, and applicable either to continuous or alternating currents.

If the meter is only applicable to one of these forms the inventor would only be entitled to half the prize.

Prizes amounting to 2,000 francs for meters intended for both alternating and continuous currents, and to 1,000 francs for meters applicable to only one of the two forms of current, will be awarded to those inventors whose apparatus shall have realized any important improvement.

The Elihu Thomson meter, which was not ready for the first competition owing to the little time allowed, obtained a first prize of 5,000 francs, as entirely fulfilling the conditions laid down.

Prof. Elihu Thomson then wished that other scientists should profit by the generosity of the city of Paris, feeling that the distinction he had gained was sufficient for himself, and he therefore charged M. E. Thurnauer, the general European agent of the Thomson-Houston Company, to organize a competition having for its object the advancement of science.

In September, 1892, the following programme was put before the scientific world through the medium of electro-technical journals.

THE ELIHU THOMSON COMPETITION.

Prof. Elihu Thomson obtained, at the last competition instituted by the city of Paris for the best electrical energy meter, a prize of 5,000 francs. Wishing this sum to be employed for the development of theoretical electrical science, he charged the undersigned, who is the general European director of the Thomson-Houston system, to form a committee for the organization of a fresh competition, the object of which should be the study of theoretical questions, the prize offered being the sum of 5,000 francs. The committee was composed of the following persons, who readily accepted the position of member. Messrs. J. Carpentier, president of the Société Internationale des Electriciens; Hippolyte Fontaine; E. Hospitalier, professor at the Ecole de Physique et de chimie industrielles of the city of Paris; E. Mascart, of the institute; A. Potier, of the institute, reporter to the competition committee; B. Abdank-Abakanowicz, consulting engineer, secretary to the competition committee.

The committee decided that the competition should bear upon the following subjects:

1. The study of the heat generated by the successive charges and discharges of condensers, varying the magnitude of the charges, the frequency, and the nature of the dielectric.

2. Theory indicates that when the armatures of a condenser have been connected by a conductor, the condenser becomes the seat of alternating currents whilst its resistance falls below a certain limit. The formula which enables the period of these oscillations to be calculated has not up to the present been fully verified. The problem set is to find this period experimentally under conditions in which the exact measurement of the resistances, capacities, and co-efficients shall be possible, so as to arrive at an accurate and complete verification of this formula.

3. When a condenser formed of an imperfect insulating material has been charged and then left to itself, the charge of the armatures is progressively dissipated; the time required to reduce this charge to a certain fraction of its initial value depends only on the nature of the insulating material. It is asked whether, as certain recent theories assume, similar phenomena occur in metallic conductors, whether there are experimental reasons for thinking so, and what is the rate of time for conductors of this kind.

4. The establishment, by co-ordinating and generalizing facts at present known, of graphic methods of solving electrical problems proceeding on the same lines as in graphic statics.

The papers presented may be written in any of the following languages: German, English, Spanish, French, Italian or Latin. They may be either written or printed.

Each of the papers presented must be marked with a certain device, and accompanied by a sealed envelope bearing on the outside the same device as the paper, and on the inside the name and address of the candidate.

The papers must be sent in before September 15, 1893, to M. B. Abdank-Abakanowicz, secretary, 7 Rue du Louvre, Paris, who will furnish any information required.

(Signed) E. THURNAUER.

Four papers were sent in in response to this appeal:

1. "Die Bewegung der Erde ist die Quelle des Lebens."

2. "Vigentia." "On dielectric hysteresis."

3. "*ηλεχτρου.*" "An examination on the absolute accuracy of the formula for calculating the period of free oscillation of a discharge condenser under circumstances such that the resistance of the circuit has no appreciable disturbing effect.

4. "*Οντις εμοι γ ονομα.*" "An experimental determination of the period of electric oscillations."

The members of the committee, after examining these papers, came to the following conclusions:

The first paper, "Die Bewegung der Erde ist die Quelle des Lebens," does not treat of the subjects specified in the programme.

No. 2 contains some very interesting facts, but does not throw any new light on the question of the hysteresis of dielectrics.

No. 3 is devoted to the verification of the formula giving the period of the oscillating discharges of a condenser. This is a very exhaustive paper accompanied by several photographs, and in it the writer has endeavored, by means of profound calculations to estimate all the corrections entailed by his method.

The verification is only approximate; the principle of the method is open to some criticism, the circuit of the discharge being closed periodically by a spark which introduces disturbances impossible to foresee.

Paper No. 4 treats of the same subject, studied by a method new in its details, and which has enabled the writer to attain and to measure periods of some hundred thousandths of a second. The influence of the principal causes of error appears to be very slight, although some doubts still remain as to the influence of the capacity belonging to the self-induction coil. The formula has been verified to within about 1 per cent. The writer had not time to complete his researches by varying the conditions of his experiments.

The report of the committee is as follows:

The committee is of opinion that paper No. 4 has gained the prize offered by Prof. Elihu Thomson, and hopes that this tribute to his ability will encourage the writer to continue his splendid researches. At the same time the committee regrets not having at its disposal two prizes of equal value to be awarded to papers 3 and 4.

The success of this competition is a matter for congratulation, for, besides the two papers referred to, others of considerable merit have been sent in.

In compliance with the wishes of the committee and in consequence of the steps taken, M. Thurnauer, Prof. E. Thomson, of Lynn, the French company for working the Thomson-Houston methods, the Meter Manufacturing Company, the chief agents for the Thomson meter in Europe, and the British Thomson-Houston Company, Limited, of London, have contributed to offer a second prize of 5,000 francs.

The envelopes containing the names of the prize papers were opened, and the committee awarded one prize of 5,000 francs to Dr. A. Webster, of Clark University, Worcester, Mass., U. S. A.(paper No.4), and another prize of 5.000 francs to Dr. Oliver Lodge. of University College, Liverpool, who collaborated with Mr. Glazebrook, of Trinity College, Cambridge, (paper No. 8).

The Secretary of the Committee,
B. Abdank-Abakanowicz.

The "Lancet" on Welsbach Lights.*

A scientific report, whether made by an expert or by a commission, is very properly expected to be strictly accurate in its conclusions, precise in its methods; and the tests applied to ascertain the facts ought to be above suspicion, and for that reason they are usually very minutely detailed in a report.

A *Lancet* Commission has just issued a report on incandescent gas lights, a copy of which we have before us. In many respects it is unsatisfactory and disappointing, and we fail to find any support in the report itself for the expressed admiration for this form of lighting, and the laudatory terms therein contained regarding incandescent lighting by gas are somewhat incomprehensible in the face of the figures given.

This remarkable production of the *Lancet* Commission begins with a long and altogether superfluous notice of the early history of gas lighting, and the subsequent discoveries of valuable products in the tar residue. Then follows a brief history of incandescent gas lighting, mentioning by the way, and recalling the fact, that there have been many previous attempts made to introduce this kind of illuminant. We have seen the "Clamond," "Lewis," "Sellon" and "Fahnejelm" systems come and go, all of them on the same principle as this last comer. The ideas of the *Lancet* Commission regarding light and heat are somewhat hazy, for they talk of the incandescent mantle converting heat rays into light rays, and say that this system of lighting is "probably the best ever obtained for the conversion of heat into light rays." Yet nowhere in the report can we find the slightest evidence to warrant such an opinion. Welsbach burners consuming 7 cubic feet per hour we find, from the figures given by the Commission, raised the temperature of a room 10·5° in one hour. Batswing (Bray's) burners, burning 12 cubic feet per hour, raised the temperature 15.5° in an hour, so that the Welsbach gave the greatest increase of heat per cubic foot of gas burnt, the ratio being $\frac{10{\cdot}5}{7} : \frac{15{\cdot}5}{12} = 1{\cdot}5$ for Welsbachs, and 1·3 for common gas burners.

The heat produced per candle-power is given for Welsbach at 0·116°, and for common burners at 0·807°; but the candle-power is doubtful, so that the figures are of but small value. We shall further on consider this question of candle-power.

There can be no mistake, however, about the heat per cubic foot burnt, as the cubic foot measurement is reliable, and so far the common burner, producing less heat, is superior. So much for the heating question; now for the production of C. O_2.

Here again the Welsbach shows to advantage; if we accept the candle-power as the basis of comparison, $\frac{CO_2}{C.P.}$ gives a good result; but as we shall presently show, it is fallacious.

The significant figures are those giving = the CO_2 increase in the atmosphere per cubic foot of gas burnt. On this basis of comparison, again, the common gas burner is better, for it gives an increase of CO_2 per cubic foot of 4·6 against the Welsbach 4·8.

We think the Commission ought to have given the measurement of the candle-powers of the lights some little attention, considering they lay such stress upon the heat and CO_2 per C. P. The statement that the light of a Welsbach burner is 50 C. P. has been accepted as correct by the commissioners, but we insist that it should be clearly defined what C. P. is meant, whether mean spherical or maximum. We must also know by what method and against what standard the light was tested. The report entirely neglects these most important essentials, and therefore the candle-power estimates and the deductions made from them are hardly worth consideration.

We have already alluded in our previous article to the errors liable to enter into candle-power measurement of lights having a high luminosity and a low diffusive power like the incandescent gas light.

Luminosity is of no value; it is diffusive power we want in an illuminant. But granted that the candle-power is greater per cubic foot burnt in a Welsbach than in a common gas burner, the arguments based upon that fact by the Commission are again fallacious.

The argument that Welsbach burners consuming 7 cubic feet instead of 12, as in the common burners, must necessarily produce less heat and less poisonous gas, only holds good in one case, and that case is not met with in practice. It holds good only if a consumer is content with the same quantity of light and a reduced gas bill. But that is not what the consumer wants; he desires to get the great increase of light promised by the Welsbach burner. This is indeed the only reason why he should make the change.

It is obviously impossible to secure both advantages. As the old saying goes, "you cannot eat your cake and have it." The increase of light is got by burning nearly the same quantity of gas in a Welsbach as we do in a common burner. We cannot get this increase of light if we wish to secure the other advantages promised by the *Lancet* Commission, namely, less heat and less CO_2. Indeed the arguments of the *Lancet* amount to this: that by means of the Welsbach we can vastly increase the light and materially reduce the gas consumption at the same time.

But that is wrong. The fact is we may obtain the same light with less consumption, or more light with the same gas expended; but it is misleading to argue that the great increase of light and the great reduction in gas consumed can both be secured simultaneously.

Another important point not touched upon by the commissioners of the *Lancet* is the minimum light practicable with Welsbach mantels. The common size, nominally 50 C. P., we have been informed, is the smallest practicable. That being so, it is evident that consumers must go in for increase of light instead of reduction of gas consumption, for as a rule they do not reduce the number of jets when the new light is adopted.

To secure all the supposed benefits of the sanitary class so much dwelt upon by the commissioners, 16, or even 12 candle-power Welsbach lights would be required to replace the common batswing burner, instead of the so-called 50-C.P. light; but the incandescent gas people know only too well that such a small light would be an utter failure with the low diffusive power at their disposal.

We have spoken of the luminosity and diffusive power of an illuminant, and perhaps it would be well to explain the distinction between the two in a physical sense. We may find a light of high luminosity which has a low diffusive power, and vice versa, and perhaps the most familiar analogy can be found in musical sounds; there may be a sound produced of high pitch, but so weak as scarcely to be heard, which corresponds to high luminosity and low diffusive power; and again, a sound of low pitch but of great loudness corresponds to low luminosity but with great diffusive power.

In light, as well as in sound, we must consider amplitude of vibration as well as frequency. Common gas burners and electric incandescent lamps, although producing light of lower frequency, have great diffusive power owing to the greater amplitude of vibration, and this is the reason why a gas light can be seen further through a fog than an arc light. The same effect is easily noted on Welsbach lights in a fog, for they become invisible long before the common gas light is obscured, thus ocularly proving their low diffusive power.

It has now become necessary in measuring lights from different sources to measure diffusive power instead of simply comparing luminosities as has hitherto been practised, as these comparisons are reliable only when the lights compared are composed of rays similar in kind and in approximately the same proportional parts. To compare two so entirely different lights as the Welsbach and an electric incandescent lamp is unfair and absurd.

All these important points are passed over in this report of the *Lancet*, and the figures widely advertised by the interested parties are accepted and put forward as if they were carefully ascertained and verified by direct tests. Against this way of examining and reporting on such a simple affair, we protest most strongly.

Now we come to the matter of the existence of carbon monoxide in the products of combustion.

The commissioners say that they found no carbon monoxide during an eight hours' test of two Welsbach lights. We are not surprised at this, for the tests were too short in duration, and the blood solution is not the most reliable test for carbon monoxide; as a conclusive test it often fails.

The carbon monoxide is not always a product of the combustion, but is often produced when the mantels become sooty; the hot free carbon then splits up the CO_2 into carbon monoxide. This reaction take place chiefly at the upper and cooler end of the incandescent mantel.

On the whole, the Commission has failed entirely to prove anything, except that from a sanitary point of view the new light is not much better than a common gas burner, and for the reasons here given we trust that the report will not in any way be taken as authoritative and conclusive.

Complete, thorough and unbiassed tests would reveal very different facts and figures from those given by the rough, brief and unsound investigation made by the *Lancet* commissioners.

Finally, we may quote some measurements and estimates made by Heim, of Hanover (*Lumière Electrique*, Vol. XXVI, page 219). A batswing burner gave 16 c. p. in a horizontal plane, with a consumption of 14·8 liters per hour per candle, and at an inclination of 45° to the horizontal, 17·2 candles with the same consumption.

An Auer-Welsbach gave 14·4 candles in a horizontal plane, and only 10·5 at an inclination of 45° with a consumption of 9.8 liters per hour per candle in the horizontal plane, the consumption being the same in the 45° plane when giving only 10·5 candles. These figures do not show the same high economy as those given by the promoters of the new light and accepted by the commissioners, and prove that only in one plane is the higher luminosity obtained from the incandescent mantel.

At the inclination of 45° the consumption in old and new lights is, according to these estimates nearly equal per candle-power hour, being, approximately, 13 liters for the Welsbach, and 14 for the batswing gas burner.

The candle power per cubic foot of gas is the rock upon which the *Lancet* splits; upon its correctness depends the whole value of the conclusions arrived at, yet upon this important point the Commission has no tests to describe nor results to give, but it ought to have formed the most important determination in the investigation.

---

*Editorial from the London "Electrical Review."

BOOK REVIEWS.

HOW TO BUILD DYNAMO-ELECTRIC MACHINERY. By EDWARD TREVERT. 8vo. 330+ix pp. Price $2.50. Lynn, Mass.: Bubier Publishing Company.

This is another attempt, and withal a very successful one, to bring within the scope of the amateur the art of constructing for his own use electrical machinery that will be of real service. The author has at the outset disclaimed the idea that it is a practical treatise, but in order that his readers may attack the problem intelligently he has been compelled to deal with the technical side of it, as well as that which by way of distinction he calls the "practical side." He seems to have handled this somewhat difficult task judiciously, thus avoiding the two rocks upon which authors sometimes wreck—empiricism on the one hand and severe technicism on the other. As explanatory and in extension of the main subject—that of electrical construction for amateurs—he has given chapters on commercial dynamos and motors. This portion of the book is less satisfactory than the rest, for little discrimination seems to have been used in selecting the "commercial" apparatus described: thus side by side are placed apparatus which has never come into commercial use and that which is regarded as standard everywhere. This juxtaposition of the two, without comment, is likely to convey the idea of equal merit for both, whereas, if public approval be any criterion, they stand far apart.

The book is well printed on heavy tinted paper, and the illustrations of the commercial machines are usually excellent, but the diagrams, which are profuse and ample, are some of them very cheap and crude. The book as a whole is well conceived, and should supply in a very satisfactory manner, the want which it is intended to fill. About the worst thing that can be said of the book is that its cover is a bright, glaring red—not the shade that is reputed to attract white horses, but of the kind that would be most aggravating to an undomesticated bull, or to the followers of Herr Most. There is nothing anarchistic between the covers of the book, but why the publishers should offend against all dictates of good taste by binding it in ugly anarchistic red is beyond comprehension.

ELECTRIC LIGHTING PLANTS—THEIR COST AND OPERATION. By W. J. BUCKLEY. 8vo. 275+iii pp. Price, $2.00. Chicago: Wm. Johnston Printing Company.

This book is unique in electrical literature, and its scope will be best defined in the author's own words:

"The purpose of this pamphlet is to give to intending purchasers of lighting plants such details as may aid them in forming a fair estimate of the cost of construction and operation of their proposed station."

The writer is neither electrician, engineer nor expert, but a salesman, identified since 1885 with what is now the Fort Wayne Electric Corporation, and, in a noble effort to deserve his salary, has mentioned no other lighting apparatus but the "Wood," as manufactured by them. For this an apology is offered, as a well-intended impartiality is otherwise observed.

"Many books are written for the engineer, fireman, dynamo tender and wireman, but few for the buyer, whose investment gives them employment, and it is the hope of the writer that the data given may aid the purchaser in the prevention of some of the usual mistakes in the first construction of his lighting plant, or assist him in the increase of the economy of its operation."

After this introduction, which is as unique as the book itself, criticism would be disarmed, but we find little cause for criticism, further than that from the introduction one is led to expect to find a trade catalogue, which this book distinctly is not. In turning over its pages we find them filled with commercial data which are valuable to every business man contemplating an investment in electrical plant, and this has been so carefully and judiciously collated as to make reference useful and satisfactory. We believe the book will fill a want not hitherto filled, and find acceptance among a wide circle.

In its make-up it lacks a table of contents, but this is probably best in a book covering such a wide variety of subjects as this, yet the full index which we should expect under these conditions is also wanting—that given being very meager. We would also like to have seen fuller data in regard to direct current incandescent lighting, but perhaps this will be supplied in a succeeding edition.

N. E. L. A.

Programme of the Cleveland Meeting.

TUESDAY, FEBRUARY 19.

Meeting of the Executive Committee at 9 A. M., Parlor 138, Hollenden Hotel.

Morning Session, 10:30 *o'clock* (*Army and Navy Hall.*)

Address of welcome by Mayor of Cleveland.
President Francisco's address.

Paper by N. W. Perry: "The Storage of Energy Essential to Central Station Economy: How It May be Accomplished and the Economies Resulting."

Discussion—John W. Langley, W. M. Stine, M. J. Perry.

Report of Committee on Relations Between Manufacturing and Central Station Companies, Frederick Nicholls chairman.

Afternoon Session, 2 *o'clock*.

Paper by E. J. Houston and A. E. Kennelly: "A New Method of Measuring Illumination."

Discussion—W. A. Anthony, C. D. Haskins, W. S. Howell, Edward Weston, L. Stieringer.

Report of Committee on Data, H. M. Swetland chairman.

Discussion—W. R. Gardener, E. L. Powers, H. W. Sexton.

Paper by Walter E. Harrington: "Correct Method of Protecting Electric Circuits."

Questions and Answers. What is it you wish to know?

Executive session.

WEDNESDAY, FEBRUARY 20.

Morning Session, 10 *o'clock*.

Paper by Edward Weston: "Some Economies in Electric Light and Power Stations."

Paper by C. N. Black: "Large Arc Dynamos."

Discussion—S. M. Hamill, J. J. Wood, F. W. Rollins, E. R. Weeks.

Topic: "How to Light Large Cities."

Discussion—Frederic Nicholls, George A. Redman, James I. Ayer, E. F. Peck, C. R. Huntley, Robert Lindsay, F. H. Clark, T. C. Smith, J. F. Morrison.

Report of Committee on Finance, John A. Seely chairman.

Questions and Answers. What is it you wish to know?

Executive session.

Afternoon Session, 2:30 *o'clock*.

Paper by E. A. Leslie: "The Operation of High Tension Currents Underground from a Physical and Financial Standpoint."

Discussion—H. J. Smith, W. H. Browne, C. H. Wilmerding, John A. Seely, C. L. Edgar.

Paper by L. B. Marks: "Arc Carbons and the Rating of Arc Lamps."

Topic: "Incandescent Lighting vs. Other Methods."

Discussion—H. T. Edgar, E. F. Phillips, W. S. Barstow, E. A. Armstrong, J. Gwynne, B. P. Holmes.

Questions and Answers. What is it you wish to know?

Executive session.

Evening Session, 8 *o'clock*.

Topic by A. J. Wurtz: "Practical Demonstrations of Protecting Lines from Lightning."

THURSDAY, FEBRUARY 21.

Morning Session, 10 *o'clock*.

Paper by Dr. Louis Bell: "The Monocyclic System."

Discussion—A. E. Kennelly, L. B. Stillwell, A. F. Kelly.

Report of Committee on Rules for Safe Wiring, Wm. J. Hammer chairman.

Topic: "Underwriters' Rules vs. National Electric Light Association Rules."

Discussion—Wm. Brophy, C. H. J. Woodbury, J. J. Burleigh, A. W. Field.

Afternoon Session, 2:30 *o'clock*.

Executive session.
Report of secretary and treasurer.
Executive Committee.
Election of officers.

Transportation Arrangements.

Mr. C. O. Baker, Jr., master of transportation, makes the following announcement:

"The various passenger associations have granted the rate of a fare and one-third for the round trip, on the certificate plan, from all points east of Chicago, Burlington, Peoria and the Mississippi River to Cleveland. Ask the ticket agent from whom you purchase your ticket for a delegate's certificate to the National Electric Light Meeting, which, when properly filled in and indorsed at the Association headquarters in Cleveland, will entitle you to return for one-third the regular fare.

"A special vestibuled train, composed of parlor cars, will leave via the New York Central and Hudson River Railroad at Grand Central Station, New York, at 9:30 A. M. Monday, February 18. Leave Albany at 1 P. M; Utica 3:17; Syracuse 4:40; Rochester 6:30; Buffalo 7:25 (Central time); Erie 9:33; arriving at Cleveland at 11:55 P. M.

"Seats for this train can be procured from C. O. Baker, Jr., 136 Liberty street, New York City, at the following rates to Cleveland: From New York and Albany, $3; Utica, $2.25; Syracuse, $2; Rochester, $1.50; Buffalo, $1.

"The passage rate from New York to Cleveland is $13; rate returning, with certificate properly indorsed, $4.35.

"As the Wagner Parlor Car Company decline to charter their cars it makes it necessary for us to pay the full rate for the entire space; therefore it is very important that the applications for space should be made at the earliest possible moment."

Personal.

Mr. Charles F. Brush has consented to deliver an address covering his reminiscences of early arc lighting at the Cleveland Convention of the N. E. L. A. It should be one of the leading features of the meeting.

The List Grows.

Among the concerns who have resented in an expressive manner the impudence of the publisher of the *Electrical World* may be mentioned, we believe, the Western Electric Company of Chicago and New York.

An Enlarging Business.

The Electrical Installation Co., the largest construction concern in the West, are about to move from their present quarters on the ninth floor of the Monadnock Building and will occupy the entire suite on the Jackson and Dearborn street front on the eleventh floor.

Standard Underground Cable Company.

The Standard Underground Cable Company has just closed a contract with Mr. J. R. Wiley to represent them in the West. with headquarters in the Rookery Building, Chicago. Mr. Wiley is well known in electrical circles, having been connected with electrical enterprises for many years, including eight years in the Metropolitan Telephone and Telegraph Company as superintendent of private lines. He is a brother of Mr. Geo. L. Wiley, who has represented the Standard Underground Cable Company in New York and the East for the past ten years. Mr. J. R. Wiley assumes the management of the Western sales department made vacant by the untimely death of the well-known and popular Fred. E. Degenhardt and was Mr. Degenhardt's personal friend. Mr. Wiley is a Western man and his family are Chicagoans.

General News.

What is Going on in the Electrical World.

Waco, Texas.—The electric street car systems and the electric light companies of Waco are to be consolidated.

Richmond, Mo.—An electric light franchise has been given by public vote to the Richmond Electric Light Company.

Mexico, N. Y.—This village has voted to have electric lights and will put in a plant as soon as arrangements can be made.

Mayfield, Pa.—A committee is communicating with several companies in regard to electrically lighting this entire borough.

Louisville, O.—Mr. Wilson, of Orrville, has asked the council for a franchise to put in an electric light plant in Louisville.

Freeport, Ill.—Meetings have been held at Cedarville to consider the question of an electric road between Cedarville and Freeport.

Peoria, Ill.—The Prospect Heights Electric Railroad Company expect to begin the building of an electric road here within six weeks.

Milwaukee, Wis.—The contract for wiring the new city hall has been given to the Western Electric Company, whose bid for the work was $14,370.83.

Wells, Minn.—The village council has let the contract for putting in an electric light plant, all complete, to Clausen & Bonwell, of St. Paul, for $6,936.

Canisteo, N. Y.—The electric railway connecting Canisteo with Hornellsville has proven so great a financial success that a rival line is to be built.

Sing Sing, N. Y.—At the coming charter election the voters will be asked by the village trustees for an appropriation of $5,000 for an electric fire alarm and other purposes.

Washington, Ill.—A boiler explosion at the local electric light works recently shattered the engine and dynamo, destroyed the building and injured five persons, one fatally.

Jacksonville, Fla.—The Board of Works announces in an advertisement that the city proposes to supply the citizens with electric lights—incandescent and arc—from its new plant.

Palatka, Fla.—The Palatka Gas, Light and Fuel Company has closed a five years' contract with the city to furnish 100 32 C. P. incandescent electric lights, and 15 2,000 C. P. arc lights for public lighting.

Ottawa, Can.—Several thousand strangers visited Ottawa during the late carnival. The electric railway carried over 125,000 people during the week without an accident and without a single hitch.

Tampa, Fla.—The Old Dominion Electrical Construction Company's bid of $8,837.50. for furnishing 250 32 C. P. lamps, and 31 2,000 C. P. arc lamps, with the necessary wiring, has been laid before the council.

Claremont, N. H.—A charter has been applied for enabling the applicants to run a line of electric cars from Claremont Junction to West Claremont, thence through the village to Newport and Sunapee Lake.

Florence, Col.—The Arkansas Valley Electric Company has started its works here and are supplying electric light to the business houses and many residences. A number of arc lights are to be erected on the streets.

Seneca Falls, N. Y.—A franchise acceptable to the company having been granted by the Board of Trustees, the construction of the electric railway to Cayuga Lake from this village will begin early in the spring.

Richmond, Va.—The city council is unanimously in favor of a city lighting plant, and it is believed the board of aldermen will be brought to vote in favor of the measure. The opposition, however, is very strong.

Kilbourn City, Wis.—There appears to be a strong probability of the electric road between Devil's Lake and Baraboo being built next summer. Parties are pushing the enterprise vigorously and with apparent success.

De Land, Fla.—The electric light company has just completed its power house. New machinery will be put in for arc lights, with which the streets are to be lighted instead of the incandescent lights used for the past two years.

Pittsburgh, Pa.—The Coraopolis and Neville Island Electric Railway has been sold to the syndicate operating the West End and the Grand Avenue Traction roads. The Carnegie branch of the West End system is nearing completion.

Kansas City, Mo.—An electric light race-track will be opened in Kansas City in the near future. Robert J. Holmes has leased the Exposition Driving Park and is negotiating for the purchase of an electric light plant with which to illuminate the track.

Athens, Ga.—The movement to convert the 1,400 H. P. of Tallesee shoals into electrical power and run it into Athens to be sold cheaply to the different manufacturing interests is still progressing. The surveyors have nearly completed their work.

Martinsburg, W. Va.—The city council has decided to ask the Legislature for permission to issue $15,000 in bonds for the purpose of securing funds to build an electric light plant. The plant is to be used in supplying light for the corporation only.

Pottsville, Pa.—A mortgage from the Schuylkill Electric Railway Company to the Real Estate Trust Company of Philadelphia, trustee, for the sum of $500,000, secured by the roads and franchises of the company, has been placed on record at the recorder's office here.

Sea Isle City, N. J.—The Sea Isle City Electric Light, Water and Power Company intend to change the present incandescent electric light system to an arc light plant. The same company are endeavoring to secure a franchise for a trolley road on Landis avenue.

Hillsborough, N. H.—A syndicate of local capitalists have purchased land and water power on the Contorcook River, about two miles below Hillsborough bridge, with the purpose of erecting an electric plant there, from which power will be transmitted to this village and also to Hermicker.

Ellsworth, Me--A gentleman of means has made a proposition to furnish two thirds of the capital necessary to build an electric road from Ellsworth Falls to deep water, or below the bar, providing one-third the total capital be raised in this city. The capital required is about $60,000.

Peekskill, N. Y.—The consents of property owners to the laying of rails of the new electric railroad in Peekskill from the railroad station to the State Camp of Instruction and to Lake Mohegan have been obtained and the company will begin the laying of rails as soon as the weather will permit.

McKeesport, Pa.—Messrs. C. H. Lloyd, Peter Shields, H. Davis, J. M. Shuck, O. C. Hartley and John J. McCloskey, of Pittsburg, stockholders in a company organized to manufacture the Borland-Fritz electric coal mining machinery, last week visited W. H. Brown's Sons' mines at Boston, where a satisfactory test of the machine was made.

White Plains, N. Y.—The New York, Elmsford and White Plains Railroad Company has received the franchise for a trolley road in this village; $2,500 is to be deposited in the White Plains Bank as a forfeit if the road is not completed by August 1. It will run to the Fair Grounds and to Silver Lake.

Lockport, N. Y.—The Standard Construction Company of New York have offered, in a communication to the mayor, to build an electric road in Lockport. to be ready for use next summer, if the city would give them a franchise guaranteed against litigation. The city officials were to consider the matter.

Iowa Falls, Iowa.—A local company has just been organized to put in an electric light plant and is capitalized at $15.000. The officers are: President, L. B. Bradley, Peoria; vice president, J. D. McKay; secretary and treasurer, H. C. Miller. The directors are these and G. A. Courtney and Z. K. Hoag.

Beaver Falls, Pa.—Arrangements are now being made by which in a few months the entire Beaver Valley, including the towns of College Hill, Beaver Falls, New Brighton, Sharon, Bridgewater, Beaver, Rochester, Freedom and Conway, will be connected with Pittsburgh by a complete line of electric street railways.

Amesbury, Mass.—It is stated here upon good authority that a deal has been made whereby the Haverhill and Amesbury electric railway and the Newburyport and Amesbury electric railway are to soon pass under the control of the Lowell Street Railway Company. For several weeks negotiations have been in progress looking toward the deal.

Morristown, N. J.—The common council at their last monthly meeting had a proposal made to them to put Welsbach lights in the park in place of the present electric arc lights, and were disposed to accept the offer on the score of economy, but the mayor thought the matter should have further consideration and on a tie vote the proposal went over.

Springfield, O.—In connection with the proposed electric railroad from this city to Urbana the promoters are considering the purchase of the beautiful property called Aberfelda, west of town, on Mad River, for the purpose of building a magnificent summer hotel for the accommodation of guests from Cincinnati, Dayton, Columbus and other places.

Buffalo, N. Y.—"It is reported on reliable authority," says the *Commercial*, "that a number of local capitalists are planning to build a new electric railway to connect Buffalo and Niagara Falls. It is understood that about two-thirds of the capital stock has been promised, and that there is every probability that the line may be built early this year."

Paw Paw, Mich.—Detroit capitalists have submitted a proposition to build a standard gauge electric railway with a 60-pound rail, fully equipped, from Paw Paw to Lawton, for a $20,000 bonus, 30 years' exclusive franchise of the streets, and a 10 years' pledge of all Paw Paw business. A committee has been instructed to continue the correspondence concerning the matter.

Fall River, Mass.—A bill before the Legislature for an electric railway is that of the Fall River and Providence Street Railway Company, of which the incorporators named are Charles F. Shaw of New Bedford, Frank S. Stevens of Swanzey, Robert T. Davis, George W. Slade, Frank W. Brightman, William F. Thomas and Benjamin Cook of Fall River. The capital stock is to be $250,000.

Grafton, Mass.—The Grafton Electric Company's new plant has been put in operation and gives great satisfaction. The lines extend over five villages—Grafton, North Grafton, Saundersville, Fisherville and Farmersville. The dynamos are of 1,000 lights capacity, of the alternating type. The station equipment was supplied by the Fort Wayne Electric Corporation of Fort Wayne, Ind.

New Orleans, La.—The St. Charles Street Railroad Company are having their roads changed to an electric system under the supervision of P. J. Partenheimer of the contracting firm of C. E. Loss & Co. of Chicago. Electricity is to be introduced also on the lines of the Canal and Claiborne Company.—There is talk on the other side of the river of building a trolley road connecting Algiers, Gretna and Harvey.

New Brighton, S. I.—The village trustees have granted franchises which in effect give three companies the privilege of constructing and operating electric roads in this village. These companies are the Staten Island Electric Railroad Company (Thomas syndicate), the Midland Company (Nathaniel Niles, president), and the Staten Island Interior Electric Railroad Company, a creation of Erastus Wyman.

Brooklyn, N. Y.—The aldermanic committee on gas and electricity has been directed to thoroughly investigate the subject of electric lighting, including contracts, specifications and the manner of carrying out the same by the different companies; also their mode of measurement and tests of lights.—The Kings County Electric Railroad Company are said to be seriously considering a change from steam to electricity as a motive power on their road.

Brockton, Mass.—The Edison Electric Illuminating Company's plant has changed hands. The purchase was made by a syndicate of capitalists, most of whom are Boston men. The majority of the new stockholders are interested in the stock of the Brockton Street Railway Co. A. A. Glasier, treasurer of the Brockton Street Railway, was elected president. E. S. Webster of Boston, J. P. Morse and H. B. Rogers of Brockton, and B. A. Reed of Boston will constitute the board of directors.

Lynchburg, Va.—Bids for building a plant capable of furnishing 300 arc lights and about 2,000 incandescent lights, and also for lighting the city by contract, will be advertised for at once. All bids must be in by February 26th, when they will be opened. Each bidder will be required to send a certified check for $500 as a guarantee of good faith. In case the city decides to build a plant, the successful bidder will have to put up a forfeit of $5,000 to guarantee the faithful carrying out of the contract.

Chicago.—The North Side and West Side trolley railway ordinances, after amendment by the mayor, have passed the council.—The Chicago Belt Line Street Railway Company have applied to council for a franchise for a street railway upon certain of the streets named in the ordinance of the General Electric Railway Company now in process of incorporation, and requests that action on said ordinance may be deferred until the Belt Line ordinance may be considered with it."

Northampton, Mass.—Lyman D. James, Alvan Barrus and others have applied for a charter as the Western Hampshire Street Railway Company to enable them to construct and operate an electric railway in the towns of Williamsburg, Goshen, Chesterfield, Worthington and Cummington, in the county of Hampshire, Mass. The applicants ask for capitalization at $150,000 and $50,000 bonds, and promise to build in five years or forfeit charter as to each town not built in. Water power will be used in generating electricity for the road, and freight will be carried.

Albany, N. Y.—The promoters of the proposed electric railway from Albany to Castleton, via Greenbush, have secured the right of way for the line. The railway will be for the accommodation of passengers and freight.—By a unanimous vote of the common council, the question of the city doing its own lighting is to be submitted to the popular vote at the next election.—A bill has been introduced in the Assembly providing that motormen and gripmen on electric roads shall be given an examination as to competency by the officers of the road before employment.—A bill has been introduced in the Assembly providing that all trolley cars shall have an appliance to determine the rate of speed, and that the maximum provided by law shall not be exceeded under severe penalties; also a bill forbidding electric cars in cities of over 500,000 to run faster than eight miles an hour.

Indianapolis, Ind.—The electric light companies of several cities in the State have united in forming an organization, to be known as the Indiana Electric Light Association, for mutual benefit "derived from an interchange of ideas born of practical experience, to the end that they may not alone cheapen the production of electric light, heat and power and protect themselves from imposition from whatever source, but also render better service in all branches of their business, thus benefiting their patrons while furthering their own interests in a legitimate business way." Meetings will be held in Indianapolis every year on the first Wednesday in February. The following officers have been elected for the first year: President, J. W. Roney, Richmond; vice president, W. K. Smith, Union City; secretary, Dallis Edwards, Decatur; executive committee, H. A. Smock, Martinsville; C. C. Perry, Indianapolis; J. W. Morrison, Frankfort; H. W. Frund, Vincennes, and J. D. Edwards, Decatur.

Telephone and Telegraph.

The contractor, James Scull, has begun work on a telephone line from Jackson, N. C., to Gumberry.

The Central New York Telephone Company have asked the common council of Utica for permission to construct underground conduits for their wires on such streets as may be deemed advisable to use.

At Berlin, Wis., there is considerable talk among stockholders of consolidating the Waushara Telephone Company with the Badger Telephone Company.

A twenty-five years' franchise has been granted to Geo. P. Eaton and associates by the city council of Tacoma, Wash., empowering them to carry on a telephone business. The ordinance provides that the company shall not charge more than $4 per month for business houses and $2.50 per month for residences, and that the company shall give the city twenty telephones at $1 each per month, and must spend $10,000 in one year after accepting the franchise.

Lawyer Simon Sterne, of New York, who is one of the most active protestants against the increased rates of the Metropolitan Telephone and Telegraph Company, has obtained a temporary injunction from Judge O'Brien restraining the company from moving the telephone instrument from his office. Mr. Sterne refused to pay the increased charge.

J. T. Foley and H. R. Winn expect to have a full Bell telephone exchange in operation in Martinsville, Ind., by June 1.

General Manager Gifford, of the Ohio Valley Telephone Company, promises to have shortly the finest telephonic lay-out in the country at his exchange in Indianapolis, and states that the American Long Distance Telephone Company will run a splendid line to Louisville from Indianapolis as soon as the weather will permit, and while that company is doing that work his company will be building a long distance line through the bluegrass fields of Kentucky to Cincinnati by way of Versailles, Lexington and other large towns in that part of the State.

E. K. Baker, superintendent of the Austin division of the Southeastern Telegraph and Telephone Company, lately stated to the Houston *Post* correspondent that his company is now engaged in making improvements in Texas that will involve an expenditure of $500,000. They are pushing the construction of their new metallic circuit for long distance speaking purposes with all possible speed. The new circuit has been completed from Dallas and North Texas to Waco. The new line from Waco to Taylor will be completed by March 1, and by April 1 will be built into Austin and pushed on to Houston and Galveston without delay.

A telephone line is being put up between Wellington and Lewiston, N. C. There will be five stations on the line—at Wellington, at Howards, Windsor, and at the telegraph station at Lewiston, where it will connect with the Western Union telegraph line, and one in the village of Lewiston.

Over 1,200 persons attended the ball of the telephone girls at Boston on Tuesday night of last week. The exchanges in the city were represented almost en masse. Many of the girls proved excellent dancers and gay and handsome ones were numerous enough to ameliorate the classical frigidity of a Boston ball room.

The Marseilles Telephone Company, composed of H. R. Adams, T. J. Neff, L. M. Jennings and R. F. Knott, just incorporated with a capital of $2,000, will set up a telephone plant in Marseilles, Ill.

The Philadelphia councils' electrical committee have reported favorably on ordinances granting privileges to the Drawbaugh Telephone and Telegraph Company and the Central Telephone Company. The ordinances had been amended and made identical at a previous meeting, and with the exception of reducing the bond from $500,000 to $100,000 the committee made no further changes in their provisions.

The Central Union Telephone Company has announced a big reduction in rates to local subscribers at Decatur, Ill. The charges henceforth will be $18 per year instead of $36 for business telephones and for residence telephones within a half mile radius of the central office $12 a year. There will be no reduction in the toll line services.

The Atlanta Bell Telephone Company are about to establish a telephone exchange at Tallahassee, Fla.

The Business Men's Association of Brookville Ind., have organized a telephone company whose operations will reach out to surrounding towns and systems.

The ordinance committee have recommended to the city council of Springfield, Ill., the passage of an ordinance reducing the per cent. of gross earnings which the new telephone company shall pay into the city treasury from 3 to 2½ per cent. A proviso was also inserted that the new company cannot sell its franchise within a year.

Preparations are being made to extend the telephone line from Pinetown, N. C., to Plymouth.

The Northwestern Telephone and Electric Company of Milwaukee will ask a franchise of the Green Bay and Fort Howard common councils for a telephone system in the two cities. The company is a rival of the Wisconsin Telephone Company and is putting in systems at Appleton, Neenah, Menasha and other Fox River Valley cities, which will be connected by a toll system.

The common council of Jamestown, N. Y., has granted the Phœnix Telephone Company of New York permission to erect a telephone system and operate the same in Jamestown.

A fire at the telephone exchange at Henderson, Ky., a few days ago burned out the city's telephone service.

A bill has been introduced in the Illinois Legislature fixing telephone rates as follows: The rate for telephones in cities of 1,000,000 inhabitants and over shall not exceed $78 per annum; in cities of 500,000 and less than 1,000,000 not to exceed $66 per annum; in cities of 100,000 and less than 500,000 not to exceed $48 per annum; and all cities less than 100,000 not to exceed $36 per annum.

In the Assembly at Albany a bill has been introduced reducing telegraph rates to 15 cents for ten words in day time and twenty words at night, and one half cent for each additional word either day or night.

Prominent members of the Minneapolis board of trade confidently assert that by this time next year the Stockholm plan of a mutual telephone company will be in force in Minneapolis. They expect to reduce the annual expense of telephones to $10 or less per subscriber after the company is once on its feet. Every one having a telephone will be a stockholder, the initiation fee being $100, and after that the expense to be levied in periodical assessments.

The Mason Telephone Company is about to remove its shops from Sumter, Ga., to Richmond, Va.

There are now twelve transatlantic cables connecting Europe with the United States and Canada, and steps have been taken to lay a cable across the Pacific from British Columbia to Australia by way of the Fiji Islands. The circle of the earth will then be completed, but not so directly as it would be by a cable from America to Japan.

An effort is being made to establish a plant of the Bell telephone in Camden, S. C.

Lincoln, Neb., is subscribing liberally for a new telephone service proposed to be given there by a company which is to use a new Chicago company's instruments.

A bill is now pending in the Missouri Legislature, and is likely to pass, which reduces the annual rental of telephones in St. Louis to $60; in all cities of the State having a population of less than 200,000 but more than 50,000 to $48 per year; in cities having a population of less than 50,000 but more than 25,000 to $30 per year, and in cities having less than 25,000 inhabitants to $20 per year. The annual rental for the use of telephones to private residences is reduced to $30 in cities having more than 50,000 inhabitants, and in cities having less than that population the price is reduced to $20 per year. The penalty for each offence is a fine of not more than $500 nor less than $100.

A telephone company is about to be organized in St. Louis, with a proposed capital of $600,000. One of the promoters states that the company proposes "to give St. Louis an up-to-date underground system in line with Eastern cities at a cost to business men of not over $60 per year and residences $48. This stipulation is embodied in the franchise we ask for and if it is possible we propose making the tariff even less. The board of directors will consist of J. J. Schultz of the Schultz Belting Company, now acting president; E. W. Stann, secretary to August Busch; Moses Greenwood, Jr., real estate; Thos. J. Ward, contractor; August A. Busch of the Anheuser-Busch Brewing Company; Clark H. Sampson. T. J. Hennessey, ex-Railroad Commissioner; Andrew Haley, real estate; J. M. O'Shea, chief grain inspector, and ex-Congressman Chas. F. Joy."

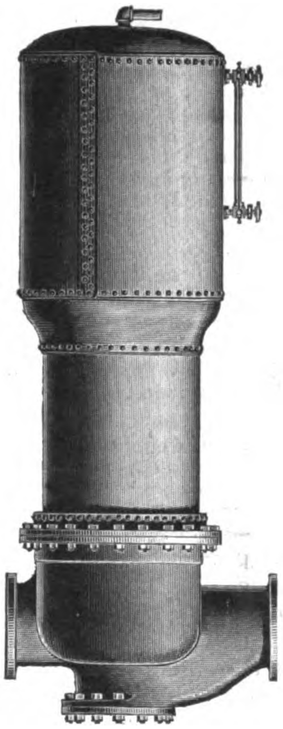
Efficiency Test of the Stratton Steam Separator.

The following report of a test of the Stratton Steam Separator, manufactured by the Goubert Manufacturing Company, 14 and 16 Church street, New York, will doubtless prove interesting to all steam users:

SIBLEY COLLEGE,
CORNELL UNIVERSITY,
R. H. THURSTON, Director.
DEPARTMENT OF EXPERIMENTAL ENGINEERING,
R. C. CARPENTER.
ITHACA, N. Y. Jan. 5, 1895.

GOUBERT MFG. CO., 14 and
16 Church Street, New
York City:

GENTLEMEN: I send you with this letter a short summary of the test which we have made on the Stratton Separator. The results show that the Separator is practically perfect, and removes all the moisture which can possibly be taken out by mechanical means. I think we will make another test in which we inject water into the steam pipe, thus increasing the percentage considerably of water in the steam supplied. This latter will not be of any great practical interest, but will bring out, of course, the capacity of the Separator for extraordinary conditions. If you have no objection I will publish a copy of this report in the next number of the Sibley *Journal*, and for that purpose would be pleased to have you loan us an electrotype showing vertical section.



STRATTON SEPARATOR.

Test of Stratton Improved Separator.

For this test the steam pipe leading to the Separator was surrounded for a portion of its length with a jacket which could be filled with water to any desired height, the purpose of the water jacket being to condense as great a per cent. of the steam as possible. The discharge of steam from the Separator was led to a surface condenser, where it was condensed and the amount carefully weighed. The drip or water discharged from the Separator was led to a barrel standing on a pair of scales and accurate weighings were made of the water taken out from the steam by the Separator. A throttling calorimeter was placed in the steam pipe directly after the steam left the Separator. Pressure gauges were placed either side of the Separator. Observations were taken and the results reduced by Messrs. Collins, Hubbard and Thomas of the Class of '94. The following is the general summary of the results: The steam supplied to the Separator contained moisture the percentage of which varied from a little over 5 to nearly 21. That discharged from the Separator was in every case nearly dry, it containing in every instance less than 1 per cent. of moisture. The Separator was worked up to its full capacity and there was no appreciable reduction of pressure. The summary of the results of different runs is given in the appended table. During these runs the water was kept at a constant height in the Separator:

No. of run.	Pressure of steam.	Moisture in steam supplied Separator. Per cent.	Moisture in steam leaving Separator. Per cent.	Quality of steam leaving Separator. Per cent of dry steam.
1	60	6.55	0.95	99.05
2	61	17.2	0.94	99.06
3	62	15 31	0.9	99.1
4	76	15.6	0.6	99.4
5	61	20.9	0.8	99.2

Respectfully submitted.
(Signed) R. C. CARPENTER.

New Catalogue.

We are in receipt of the new catalogue of Railway Material just issued by the Central Electric Company of Chicago. It is a handsomely gotten up pamphlet of 164 pages, with flexible cloth covers, and contains everything imaginable in the electric railway construction line. It is profusely illustrated with wood cuts of the various fixtures and appliances, and thus constitutes the most complete compendium of electric railway goods that has ever been called to our attention. It will prove of great value to the electrical fraternity at large, and aside from its intrinsic merit is too good to throw away. Unfortunately, there are many catalogues of which this cannot be truthfully said. Copies may be had on application to the Central Electric Company, 173-175 Adams street, Chicago, Ill.

The Hart & Hegeman Manufacturing Company of Hartford, Conn., have ready for circulation their catalogue "B," which contains descriptions, dimensions, capacities and prices of their celebrated switches, etc., with illustrations of the various sizes from 5 to 50 amperes, single and double pole. There are also illustrations of the flush plates used with the regular Hart switches, and explanations of the various features that have commended the switches and appendages to users and the trade.

RECENT COMPANY ELECTIONS.

The West Shore Telephone Company, Kingston, N. Y. Directors: Dr. C. O. Sahler, F. D. Winne, Henry Abbey, Enoch Carter, Dr. R. Thompson, Clarence Schoonmaker, Kingston; H. C. Tillson, M. A. Presler, Highland; W. S. Ransley, G. S. Clark, Dr. W. B. Snow, Milton; Davis Winne, The Corner; A. L. F. Deyo, Gardiner.

Hamilton, Grimsby and Beamsville Electric Railway Company, Hamilton, Can. President, C. J. Myles; vice-president, Thomas W. Lester; secretary and treasurer, Adam Rutherford. Directors; John Hoodless, C. J. Myles, Thomas W. Lester, A. H. Myles, Walter Grieve, John Gage and Robert Ramsay.

Carbondale Electric Light Company, Carbondale, Pa. President, E. Clarkson; vice-president, E.W. Mills; treasurer, Joseph Birkett; secretary, George Herbert. Directors: Joseph Birkett, J. Edwin Watt, E. W. Mills, C. O. Mellen and Edward Clarkson.

Molyneux Electric Manufacturing Company, Buffalo, N. Y. President, Edgar Van Etten, of New York; vice-president, H. Walter Webb, of New York; treasurer, Frank Hammond; secretary, Walter P. Trible; general manager, J. W. Cobb; electrical superintendent, Barton S. Molyneux.

Detroit Electric Light and Power Company. All of the old board were re-elected and the directors elected officers as follows: F. F. Palms, president; George M. Vail, vice-president; William S. Crane, treasurer; William H. Fitzgerald, secretary and manager.

Baltimore Traction Company, Baltimore, Md. President, Frank Brown; vice-president, J. S. Hagerty; treasurer, Frank S. Hambleton; secretary, J. Clarence Bowerman; general manager, W. A. House, Jr. Directors: P. A. B. Widener, William L. Elkins and Sidney F. Tyler, of Philadelphia; and Howard Munnikhuysen, John A. Hambleton, Henry A. Parr, T. Edward Hambleton, James S. Hagerty and Frank Brown, of Baltimore.

Trenton Passenger Railway Company, Trenton, N. J. President, Henry C. Moore; vice-president, Thomas Barr; treasurer and secretary, John L. Kuser. Directors: Henry C. Moore, Thomas Barr, E. J. Moore, Col. A. R. Kuser and Ferdinand W. Roebling. Two of the old directors, S. K. Wilson and Barclay Stokes, were dropped.

The directors of the Ballston Spa Electric Railroad Company have elected the following officers: President, Thos. Craig; vice-president, Thomas Kerley; treasurer, Chas. E. W. Smith; secretary, Frederick R. Barnes.

Owego Electric Light and Power Company, Owego, N Y President, Dr. C. R. Heaton; vice-president, E. W. Stone; secretary and treasurer, George F. Andrews; manager and superintendent, Horace Yothers. Directors: Wm. Phelps, Hon. George F. Lyon, Binghamton; Wm. S. Truman, George F. Andrews, E. W. Stone, Dr. E. A. Mayor and Dr C. R. Heaton.

INCORPORATIONS.

The General Electric Railway Company, Chicago.—to deal in railway appliances. Capital stock, $1,000,000. Incorporators: Daniel M. Simmons, William A. Youmans and George Pfleger.

The Electric Light Photographic Company, Chicago. Capital stock, $5,000. Incorporators: Oscar L. Sturtz, Robert E. Brown and Chris Florup.

The Rahway Electric Light and Power Company, Rahway, N. J.—to furnish light and power, especially power to operate the new electric railway in Rahway. Capital stock, $200,000. Incorporators: Capt. C. W. Boynton, of Woodbridge; Henry Mourer, Robert W. De Forest and Frank A. Patterson, of New York City; H. W. Thiele, of Brooklyn; H. W. Douty of Asbury Park, and Jackson Jacques, of Rahway.

The Newton Light and Power Company, Newton, Kan. —to furnish light, heat and power to the city of Newton and its inhabitants. Capital stock, $50,000. Promoters: Lewis B. Gawtry, N. Y. City; Julius A. Bailey, Philadelphia; John C. Nicholson, Newton.

The San Antonio Electric Company, San Antonio, Texas. —to manufacture and sell electric light, heat and power for all purposes. Capital stock, $100,000. Promoters: Ronald T. McDonald, Edward J. O'Beirne, Wm. H. McGaw.

The United Switch Company, Newark, N. J.—to buy, sell, lease, license and manufacture electrical machinery and apparatus in Newark and New York. Capital stock, $100,000. Incorporators: Henry C. Hines, William C. Morton and Robert D. Beatty, all of Newark.

The Llanerch Heat and Light Company, Llanerch, Pa.—to supply light, heat and power, or any of them by means of electricity. Capital stock, $25,000. Promoters: Edw. Worth, Mercer Strong, Wawa, Pa.; Frank A. Hays, Lansdowne, Pa.

The Electric Kindling Wood Company, Jersey City, N.J. —to manufacture, buy and sell "electric kindling wood," etc., and buy and sell all kinds of lumber. Capital stock, $10,000. Promoters: Chas. L. Netting, Jr.; Fred. W. Aldrich, Pittsburg, Pa.; C. Blake Garrison, Bayonne City, N. J.

The Stadacoma Water, Light and Power Company, Montreal, Can.—to furnish water and electric light to towns and villages in the province of Quebec. Capital stock, $40,000. Incorporators: Louis H. Tache, advocate; Joseph O. C. Mignault, Ernest Belanger, Edouard Charles Amos, civil engineers, and Charles de Bellefeuille Macdonald, of Montreal.

Woven Wire Brushes.

The Belknap Motor Company of Portland, Me., are the patentees and manufacturers of the best Woven Wire Brush on the market.—[*Adv.*

ELECTRICAL PATENT RECORD.

LETTERS PATENT ISSUED FEBRUARY 5, 1895.

ELECTRIC RAILROADS AND APPLIANCES.

533,447. Electric Railway. John G. Douty, Williamsport, Pa., assignor of two-thirds to James N. Kline and William G. Elliot, same place. Filed May 17, 1894.

533,598. Running-Gear for Electric Cars. Charles A. Jackson, Reading, Mass. Filed Sept. 15, 1893.

533,610. Conduit Electric Railway. Alfred Rosenholz, San Francisco, Cal., assignor of one-half to Samuel J. Clarke and Harvey S. Brown, same place. Filed May 22, 1894.

533,627. Conduit Electric Railway. William H. Baker, Pawtucket, R. I. Filed May 18, 1894.

533,631. Subway for Electric Railways. Frank E. Button, Rochester, N. Y. Filed June 6, 1894.

533,772. Trolley for Underground Conduits. Charles M. Yost, Washington, D. C., assignor of forty-one eightieths to Gabriel Edmondston, Lemuel F. Burner and Georgianna T. King, same place. Filed Nov. 3, 1894.

533,836. Conduit System, Charles M. Yost, Washington, D. C., assignor of forty-one eightieths to Gabriel Edmonston, Lemuel F. Burner and Georgianna T. King, same place. Filed Nov. 3, 1894.

ELECTRIC LIGHTS AND APPLIANCES.

533,434. Rosette for Electric Lighting. Elisha W. Buffington, Fall River, Mass., assignor of one-half to Albert F. Dow, same place. Filed Oct. 6, 1894.

533,459. Electrically-Lighted Buoy. Ira W. Henry, New York, N. Y. Filed May 29, 1893.

533,502. Method of and Means for Testing Incandescent Lamps. Frank S. Smith, Pittsburg, and James A. Vandegrift, Allegheny, Pa. Filed July 9, 1894.

533,670. Lock for Electric Lamps. Warren A. Saul and Jacob H. Peck, Steelton, Pa. Filed March 13, 1894.

533,853. Cover for Electric-Light Globes. Hans Johansen, Chicago, Ill. Filed June 30, 1893.

DYNAMOS, MOTORS, ETC.

533,445. Electric Dental Motor Apparatus. Francis N. Denison, Toronto, Canada. Filed May 26, 1894.

533,583. Brush for Dynamo-Electric Machines. Joseph W. Dickey, New York, N. Y., assignor of one-half to Charles E. Chapin, same place and Milford, Conn. Filed Dec. 8, 1894.

533,833. Rotary Brush. Harold A. Webster, Haverhill, assignor to the Globe Buffer Company, Boston, Mass. Filed April 27, 1894.

TELEPHONE AND TELEGRAPH APPARATUS.

533,427. Automatic Telephone-Switch, Henry D. Bayne, Brooklyn, N. Y. Filed May 31, 1894.

533,619. Telephone Arm-Rest and Receiver-Holder. William Steubing, Cincinnati, Ohio, assignor of one-half to Frank A. Leininger, same place. Filed Oct. 30, 1894.

EDITORIAL NOTES.

Central Station Economy. The supply of gas and electricity for illuminating purposes involve nearly identically the same engineering problems. In both cases the pressure at which distribution may take place is limited by the pressure at which it can be most economically used at the lamps and the drop in line. That is to say, the initial pressure cannot exceed that at which the lamp burns most economically plus the loss in pressure in transmission. In both cases the best consumption pressure is low, in both cases the distribution is at constant pressure, and since the character of the service is the same, the load lines of the gas company and of the central electric lighting station will, under similar circumstances, be subject to the same wide variations from the straight line which would indicate a constant load extending throughout the twenty-four hours. Both commodities are produced from the same crude material, viz., coal, both go through somewhat similar transformations in the course of manufacture, are distributed under similar conditions and finally come in direct competition in the same service. In this competition the gas light is sold at a figure considerably lower than the electric light—with gas at $1.25 and electricity at 1 cent per lamp hour, assuming that a 16 C. P. incandescent lamp is the equivalent of a 5 foot burner, the price of gas light is but 62½ per cent. of that charged for electric light. That there can be any competition with this disparity in cost implies an intrinsic merit in the electric light that is gratifying to those who have made electricity and electrical methods their life work.

Let us see how the profits of the two at these prices compare. Picking up a recent gas journal we checked off the prices bid for common stock of twenty-four gas companies in nine of the leading cities of this country and found them to average $223.46 on a par value of $100. Seven of the most prosperous electric lighting companies in this country, representing six cities, give an average value for their stocks of $86.86 on a par value of $100.

This is to say that the gas company which sells its product 87½ per cent. cheaper than electricity is sold and can get for its stock 2.57 times as much as the electric light manufacturer can get for his stock. It is very evident from this that the gas manufacturer is not selling his product below the cost of production, and it behooves us to inquire wherein lies the secret of his cheaper production.

It has been frequently stated that a given quantity of gas burned in a gas engine, through the intermediary of the dynamo will produce more light than can be obtained by burning that gas direct in the ordinary batwing or fishtail gas burner. At first blush such a statement seems extravagant to the highest degree, but a glance at the figures will show that it is well founded in fact.

Gas engines showing a thermal efficiency of 20 per cent. and a mechanical efficiency of 85 per cent. are to day well known, and higher figures than these are obtained under test conditions.

Incandescent lamps consuming 3.5 watts per candle power are no longer considered high efficiency lamps. Such a lamp converts about 6 per cent. of all the energy it receives into luminous rays—its true light efficiency is therefore 6 per cent.

Dynamos with a guaranteed efficiency of 95 per cent. are manufactured by all the leading electrical concerns in the business.

All of the gas engine manufacturers guarantee the production of 1 brake H. P. with a consumption of less than 20 cubic feet of ordinary illuminating gas per hour.

Let us assume 15 per cent. loss between engine pulley and dynamo pulley and 5 per cent. to cover other losses in getting the current to our lamps, assumed to be near at hand. We then have the following chain of efficiencies:

20 per cent. thermal efficiency of gas engine.

85 per cent. mechanical efficiency of gas engine.

85 per cent. efficiency of mechanical transmission between engine and dynamo.

95 per cent. electrical efficiency of dynamo.

95 per cent. efficiency of electrical transmission between dynamo and lamps.

6 per cent. luminous efficiency of lamps.

This gives us as the final efficiency between our gas and electric lamp :

20 p.c. X 85 p.c. X 85 p.c. X 95 p.c X 95 p.c. X
6 p.c. $=\frac{748}{1000}$ of 1 per cent.

Prof. Tyndall gives the light efficiency of the ordinary gas burner as $\frac{317}{1000}$ of 1 per cent.

Allowing nothing for losses in transmission of gas to the burners, which are also assumed to be close at hand, we see that notwithstanding the losses incurred in the several transmissions and transformations involved in producing light from gas through the intermediary of the gas engine, dynamo and incandescent lamp, we still have over 2¼ times (2.344) the light efficiency that we have in burning gas direct. Or in other words, we can produce from a given quantity of gas, by burning it in a gas engine, 2¼ times as much light as we can by burning it direct in the ordinary way.

The figures upon which this calculation is based are all so conservative that the results cannot, we think, be successfully refuted. As a matter of fact gas engine manufacturers, both in this country and abroad, will guarantee the production of better than ten 16 c. p. incandescent lamps on a consumption of 20 cubic feet of ordinary illuminating gas per hour, which would give a ratio of 2½ to 1 in favor of electricity, and we have ourselves seen a 10 h. p. gas engine working at about half load produce 56 full candle power 16 c. p. lamps on a consumption of 160 cubic feet of New York City gas per hour. Since 160 cubic feet would supply 32 five foot burners, the ratio under these very uneconomical conditions of working of the engine was 1.75 to 1.

These results show most conclusively that so far as the conditions of *manufacture* are concerned the electric light can be produced far more cheaply than gas light as usually produced.

We have thus far in speaking of gas light been careful to qualify it as that produced in an ordinary batwing or fishtail burner, thus excluding from comparison the incandescent gas burners which produce light much more efficiently. If, however, we compare the best electricity can do with the best that gas can do, using the arc lamp and the Welsbach burner as our units for comparison, the qualification which was necessary before becomes no longer necessary. For if we assume a 500 watt (nominal 2,000 c. p.) arc lamp to produce an illumination equal to 1,000 candles, 20 cubic feet of gas will produce $\frac{746}{500}$ X 1,000 X .80 per cent. (allowing a loss of 20 per cent. between engine pulley and lamp)=1,193.6. Extravagant claims have been made for the Welsbach light, but assuming the highest figures claimed by the American manufacturers, viz., 55 c. p. from 4.6 cubic feet of gas, we have for 20 cubic feet an illumination equal to $\frac{20}{4.6}$ X 55=239.1 or a ratio of 4.99 to 1 in favor of electricity.

From this it will be perfectly clear that electric light can be *manufactured* at a fraction of the cost to manufacture gas light, and this statement requires no qualification whatever.

That it *is not* manufactured at this price we all know, and this is due to several causes, many of which are wholly or partially remedial. In the first place our central stations have cost too much. The fixed charges are out of all proportion to the working expenses. This is partly correcting itself, for any of the stations erected two or three years ago could be duplicated to-day at half what they then cost.

In the second place there is the unsatisfactory load line which requires us to install two, three, and sometimes four times the amount of machinery required for the mean output. The load line we cannot correct, but we can minimize our fixed charges and operating expenses by a judicious storage of energy. This seems by far the most fruitful field for improvement in central station practice and we are glad that the subject is going to attract attention at the Convention.

* * *

Our Convention Number. Electricity gives greeting to the members of the National Electric Light Association on this the tenth anniversary of its birth. In recognition of the occasion we appear in gala garb and with special inward features which we trust will prove no less attractive than the graceful figure which adorns the outside page. Since some space within the covers is devoted to the use of the electric light in church symbolism and adornment, it seemed not inappropriate that symbolism should find a place on the outside also. In casting about for an idea that should be most fitting for the occasion, we sought that which most truly typified the benign influences which the electric rays have shed upon mankind. The progress of the art has not been one of carnage or of force; hence Ajax defying the lightning, nor his reputed wife with lamp aloft looking for burglars, nor forked lightning annihilating the Quaker kite, that have so often done duty, seemed appropriate. Rather has her progress been one of gentleness, conquering by force of beauty and of grace. These are her attributes, and these are the attributes of the female figure whose beauty is most adorned when unadorned. What more appropriate then than the personification of Hogarth's curves, which our artist has so attractively depicted, holding aloft, in a novel way to be sure—for all her ways are novel—the soft and gentle light which dispels the clouds of darkness that until her advent enveloped us all. This is the good genius of Electricity, and with this introduction she also bids you greeting.

It seems eminently fitting on this occasion that we should present the portraits of those who from the beginning, or from near the beginning, have both by precept and example, while enlightening their benighted brethren as to the inherent merits of a blue dynamo, a red motor, a barber pole insulation, or an arc light that saves current by going out, inspired respect for the truth—it seems meet (and drink) that this noble adherence to the strictest truth, which has not been equalled since the days of the elder Ananias, should at this time be commemorated, and it is done. We only ask our readers to gaze upon these faces in which there is no guile and realize how fully virtue is its own reward. For what else on earth have they ? And if this, too, be gone, what have they?

It seems fitting also that the fountain head whence is drawn all the inspiration on electrical matters that has made life worth living to the electrical business man since the real birth of Electricity on July 22, 1892, should be presented for our beneficiaries to gaze upon. Modesty forbids us from saying much of ourselves—we prefer to let the light of our countenances as here depicted speak for us. But this we will say, we do not pride ourselves on an ancestry hidden in the dim vistas of the past. Unlike the patient mule whose pedigree is enveloped in doubt, ours is certain and sure, and no stain rests thereon. We are not of the past but of the present. We never invented a new geometrical figure whose ratio of perimeter to diameter was unity. We never tossed up pennies with the electrical fountains at the World's Fair to see whose turn it was to thrill and whose to throb, or described their 8 foot high caissons as tall enough to permit of a man walking around in them erect. Although we did come from Chicago, and it is to our credit that we *came* instead of *remained*, we never, when reading the beautiful story of Pygmalion, assumed it to be an allusion to the chief source of wealth of the Western metropolis. Nor did we ever, when our candidate for treasurer of the Institute was assailed on the heinous charge of not being himself an electrician, hurl back the unanswerable argument that *he* was because his father before him was engaged in electrical pursuits. In all these things we have failed, but we plead in extenuation our extreme youth—such honors only come with age. Yet are we content.

* * *

The Policy, Not The Men. As usual at Convention times, the G. E. Company will be represented by a corps of bright and gentlemanly young men, any one of whom, in personal matters, would be worthy of full confidence.

But central station men and others in choosing the manufacturing company with which it is most desirable to do business must look behind the character and personality of the salesmen, and consider the policy of the company, with which the salesmen have nothing to do.

The policy of the G. E. Company cannot be made clearer than by reprinting the following from our issue of January 2 :

> At the time of the G. E. consolidation the Denver Consolidated Company was buying everything from the G. E. Company, its purchases amounting to several thousand dollars monthly. The company was prosperous and had declined several overtures to mix itself up in financial deals with the Eastern people. Soon after coming to New York, Mr. Coffin called one of his agents into his private office and said to him :
>
> "You are pretty well acquainted at Denver and we want some special work done there. You remember a few years ago we decided to start a small opposition company there, and they finally bought us out. We made a handsome profit. Now the Denver Consolidated Company has a capital of $1,000,000 and we must have some of it; it is good stock and pays 10 per cent. annually. We think you ought to go to your friends there and organize a new company. The Consolidated people would probably prefer not to be hostile to us and might give us about $250,000 of that stock. You see, I know all of Mr. Rawlins's (president of the Denver Company), financial friends in the East, and might have some influence on them in future deals of his if

he chose to be unreasonable. Now, you go out to Denver and scorch them at that end and I will burn them up at this end."

Few companies desire to be either scorched at one end or burned up at the other.

* * *

A Vicious Policy. Soon after the final victory of the General Electric Company in establishing the legal validity of the Edison lamp patent, there was a meeting of the various heads of departments, district managers, etc., to discuss the changed situation. Mr. Coffin, the president, presided. Before the meeting closed one of the district managers asked:

"What will be our policy toward previous users of infringing lamps, and what will be your policy towards the makers of those lamps?"

Mr. Coffin was silent for a few seconds and replied:

"**Vicious!**"

The word was hissed out with inexpressible malignity, and among those present there were some who could see from that minute the final doom of the company and its policy.

There have been many expressions of opinion as to just who was responsible for the evil policy which has done more, perhaps, than any other one feature of the mismanagement to wreck a great enterprise. Some have placed the responsibility on Mr. F. P. Fish, others upon Mr. Twombly and Mr. Coster. It is not surprising that none of these gentlemen has come forward to claim the honor.

It is apparent that the honor must rest with Mr. Charles A. Coffin, and the downfall of the company can be dated back to the utterance of that one word—VICIOUS!

Under the Searchlight.

Views and Opinions on Timely Topics.

Special Issue No. 2.

The artistic cover which adorns this week's issue of ELECTRICITY will be continued on the issue containing the Convention report. Advertisers who have not availed themselves of the opportunity of being in the first special issue may place their orders for space in No. 2. at Parlor 139, Hollenden Hotel.

* * *

When the time comes we shall enjoy the explanation which the G. E. Company gives of the methods employed in securing its blanket charter at Albany. Who got the $50,000 *or* $60,000 *which was paid at that time to Mr.* F. *Worked-'em-all Webster for mica which has not yet been delivered?*

ELECTRICITY *has several things on ice.*

* * *

New York for the Convention.

If the members of the Executive Committee of the N. E. L. A. act with perfect wisdom New York will be chosen for the next annual meeting place. An opportunity for exhibits such as has never before been offered is at our disposal. We can entertain the guests in a way never to be forgotten. New York is the place.

* * *

EVERY solicitor ever employed by this paper has been forbidden to recommend any concern to take its advertisement out of any other paper and give it to ELECTRICITY. We want business as much as any paper published, but we want it on the merits of our own paper.

* * *

A PHENOMENON.

A Tiffin House Chock Full of Electricity.

(Tiffin, O., despatch to Cincinnati Enquirer.)

One of the most peculiar things that has ever come to light in this city is the presence of electricity in the front room of Dr. H. K. Hershiser's residence on Monroe street in this city. Any one touching a metallic substance in that room, be it the chandelier, stove or trimmings on the piano, instantly receives such an electric shock as to almost knock him down. The instant the hand touches the metallic substance the electric snap is heard, and the electric spark, as from a dynamo, is quickly felt. People have been flocking to the Hershiser home for several days to witness the peculiar phenomenon. A person holding his fingers within an inch of another person's face would see a spark and feel a shock as if he had touched the stove. An individual putting two fingers together on either side of a chandelier gas jet would quickly light the gas. The cause of the presence of the immense amount of electricity can only be surmised. Some attribute it to possibly some electric substance in the coal which is burned in the stove in the room, the stove diffusing the electric substance throughout the apartment. Some say that electricity is always more or less present in a room in which the floor is covered with moquette carpet, but as this room is covered with ingrain carpet it makes it the more strange.

Some also say that the average reporter, in writing of electrical fakes, falls down far short of the climax. The above, from a critical point of view, is like Falstaff without a stomach or Trilby without feet. If the writer had been a true artist he would have added that the local light and railway companies had abolished steam and were now getting all their power direct from a connection with Mr. Hershiser's chandelier, or stove, or ingrain carpet.

* * *

It is reported from Boston that a director of the Davidson Fan Motor Company recently entertained a prominent New York man at lunch at a Boston club. Later the company sent a bill to the gentleman for $6.90 for the entertainment.

* * *

MR. L. E. MYERS, of Chicago, recently received a proposition to put in an electric light plant in Missouri in exchange for some Tennessee farm land—some of the land, we suppose, which the Eastern delegation saw on its way to Atlanta. The gentleman's business card read as follows:

F. M. Miller, Lathrop, Mo., real estate and exchange commission merchant. For sale or trade: all kinds of real estate or personal property; farms—improved and unimproved; all kinds of city property; store buildings, with or without stocks of goods; stocks of goods of all kinds; fire proof safes, soda fountains, billiard and poo tables, mill property, novelty works, livery stables, blacksmith shops, hotels, opera houses, electric light and ry. works, pop factories, patent rights. In fact everything. Send me a list or description of your property—it don't matter what it is, I will sell it. No sale or trade no charge. My charges are very reasonable.

* * *

HIS REMARKABLE TROUSERS.

A Well-known Electrical Man Creates a Sensation in Broadway.

(From a Daily Paper.)

Pedestrians in Broadway near the City Hall park yesterday were startled by a vision of peculiar brightness, which, at a distance, seemed like a halo of myriad colors surrounding the legs of a gentleman who was plodding along, all unconscious, apparently, of the fact that even the horses were blinded as he approached. With the aid of a sun-glass it was discovered that the shock was produced by the most wonderful pair of trousers ever seen in our streets.

Who was he? 'Tis needless to answer. He is, as it were, too well known to need description. These trousers may be seen at the Cleveland Convention.

* * *

IF Mr. Brobst will engage W. J. Johnston to pass through his cold storage room on the way to breakfast every morning he will not need to buy any ice during the Cleveland meeting.

INTERESTING INFORMATION.

Late Circular Letter Not Intended for Publication.

SCHENECTADY, N. Y., Jan., 1895.

Dear Sir:

Enclosed herewith I send you the monthly summary of isolated and central station lighting business secured by the various local offices for the month of December. The total amounts to $118,585. which is somewhat less than the record for the previous month. The opposition again come very close to us with $106.312. This amount would be increased to nearly the same figure as the business secured by us if all the reports had been received. As it is, we have been obliged to hold several over until next month.

Isolated Lighting.—We have closed fifty-three contracts, amounting to $76,825, while our competitors have taken twenty-six, amounting to a little over $52,000. This includes two large bids of about $9,500 each; one for the Library of Congress at Washington, and the other a revised bid for the American Surety Company, which was reported in my October letter. In five cases the opposition's figures have been reported, and we note that the average is only 8 per cent. below us, which is too small a difference to account for the large amount of business they have secured, and there can be no doubt that the OPPOSITION ARE SECURING A LARGER AMOUNT OF BUSINESS THAN IS INDICATED BY THESE REPORTS. There must be instances of small plants where purchasers consider that the General Electric Company is "too large" a concern to care for such "small business," but I would remind you that it is the sales where we sell the apparatus outright for cash that are the profitable ones, as they do not entail any large amount of office work, neither is there any delay caused by construction work. I would also like to impress upon the agents the advisability of following up such installations as are secured by our competitors, to see how the purchaser is satisfied with his apparatus, and also, if possible, to gain some knowledge as to how the apparatus itself behaves under working conditions. Although it is not always advisable to refer to a competitor's plant that is giving poor satisfaction, it is often advantageous to know how they work, so that comparisons may be made.

Central Station.—Owing to the loss of our proposal to the Citizens' Electric Company of Springfield, Ill., which amounted to $46,488, the amount of business ($54,299) secured by our competitors is considerably more than that secured by us, which amounts to $42,260. We are advised by our Chicago office that the erection of this plant depends upon their ability to secure the contract for lighting the city. While increase in amount of business reported as secured by our competitors is, no doubt, due to more care being taken in our local offices in reporting the same, *we still feel that some of our offices are not reporting small business* taken by our competitors upon which we do not have *an opportunity to bid.* I wish to impress upon you that cases of this kind should be embodied in your weekly report to each department manager (copy of which you send to the First Vice-President), as they are of as much interest as those cases where we have also put in bids.

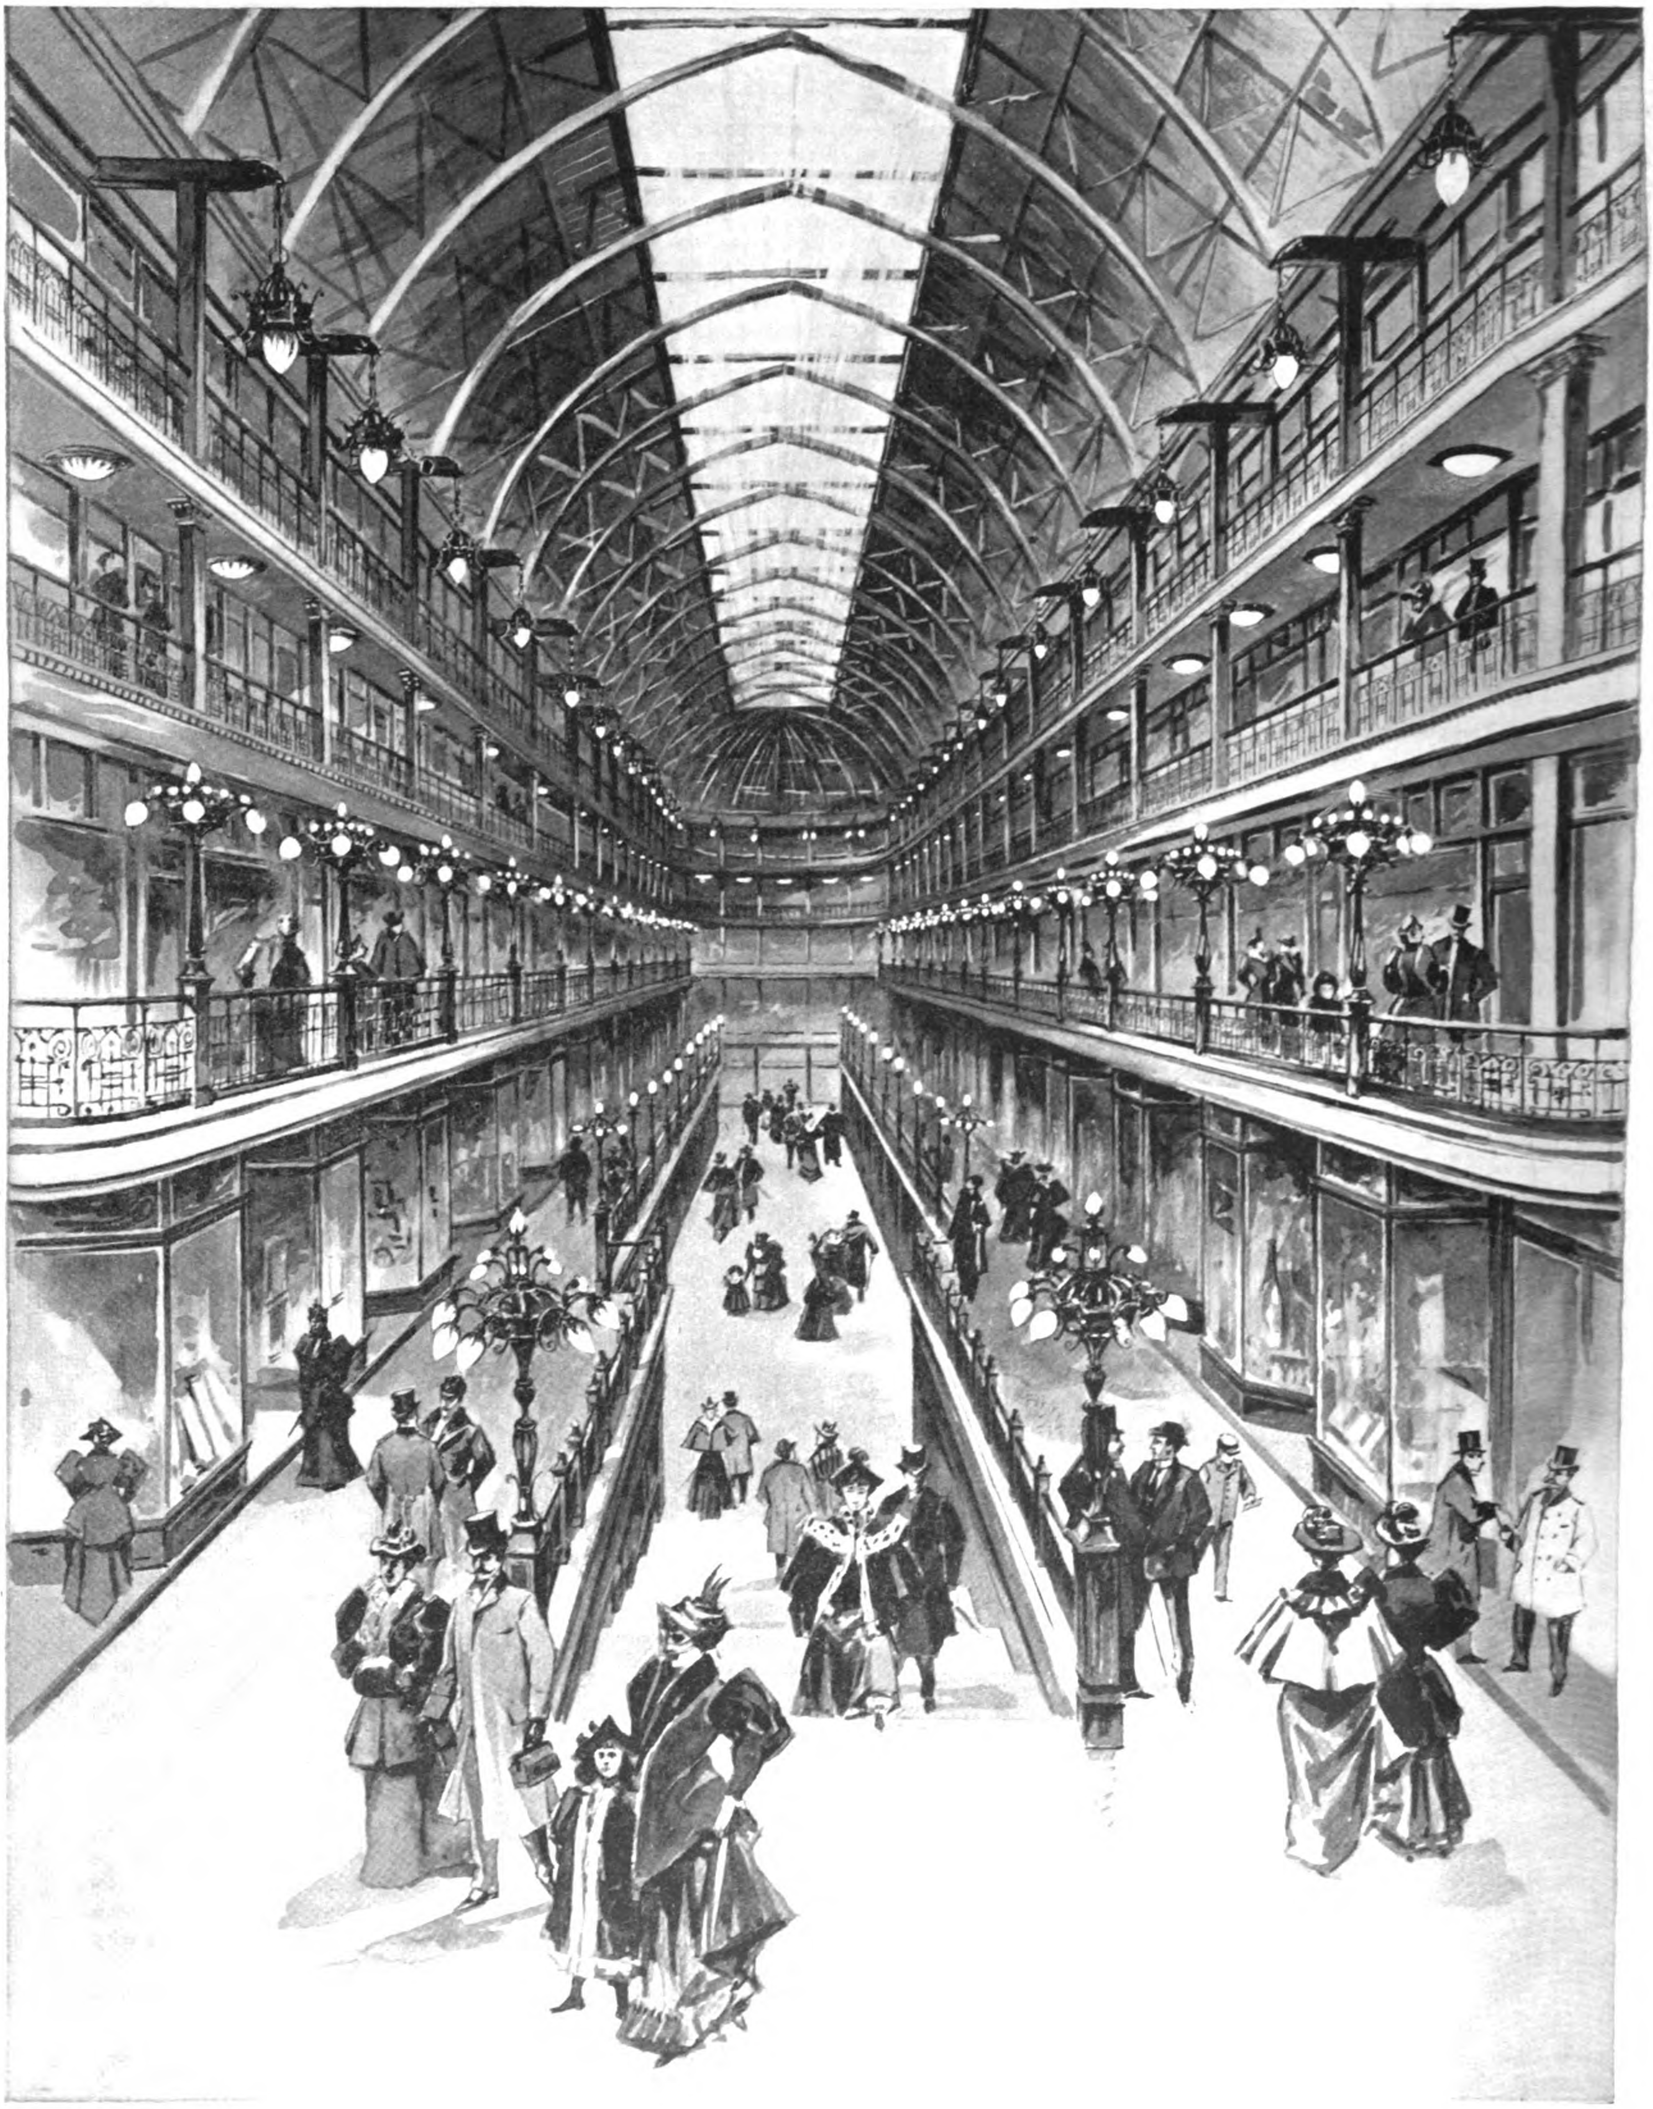
I have noticed that some of the local managers do not seem to understand the instructions issued by the First Vice-President contained in Circular Letter No. 4, regarding the reporting of business secured by our competitors. It is desired that each manager shall send to me each week a letter stating what lighting business has gone to the opposition during the week, with a brief review of the circumstances of each case. A copy of this letter should be sent to the First Vice-President. Those offices who have neglected this matter heretofore will please take particular pains in the future. I might add that this should be done for each department.

Yours very truly,
(Signed) S. D. GREENE,
General Manager Lighting Department.

Mr. Greene is entirely correct in supposing that his agents have not reported *all* the business closed by the independent companies. If the actual figures were attainable it would be seen that the great $50,000,000 corporation is a very poor second in the race.

The fact which stands out clearly from the statements above is that the independent concerns are doing the *profitable* part of the business and leaving the tailings to the G. E. Company.

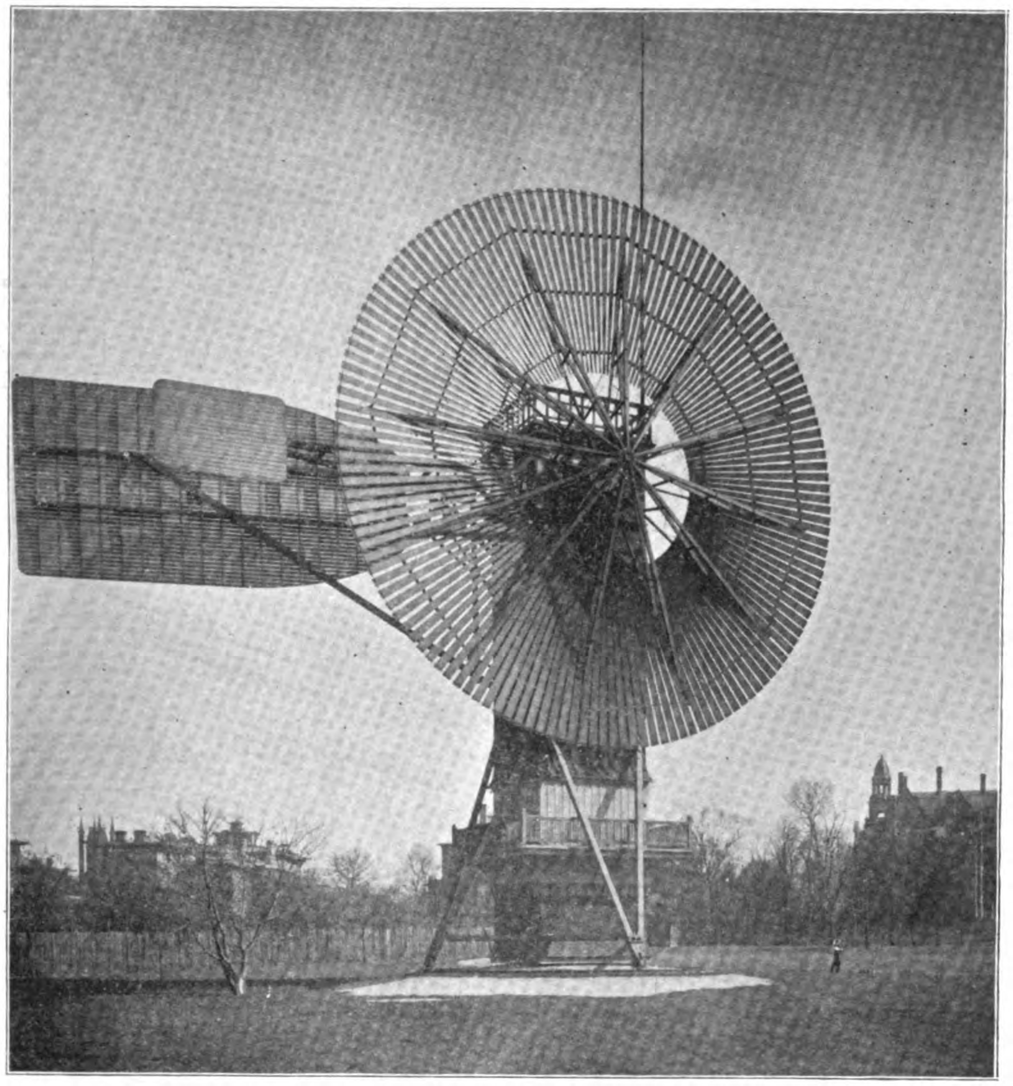
A Lighting Suggestion for the Cleveland Arcade Building.



THE GREAT BRUSH WINDMILL LIGHTING PLANT.

There is probably no electric light man in the country that has not heard of the great windmill plant employed by Mr. Chas. F. Brush to light his residence on Euclid avenue, Cleveland, nor any that has not promised to avail himself of the first opportunity of visiting it; and now that the National Electric Light Association is holding its Convention in Cleveland that opportunity, so long delayed to many, seems to present itself in a most attractive form. It seems appropriate, therefore, to give the subject some attention in this issue, and in connection with the accompanying engraving, reproduced from the most recent photograph, especially taken for Electricity, the following data will be of interest.

The history of windmill power as applied to ctric lighting begins in this country with this plant, which was erected by Mr. Chas. F. Brush in 1887 and which without question constitutes the most unique private electric lighting plant in America. Every contingency is provided for, and the entire apparatus from the huge 56 ft. wheel of the mill down to the most delicate electrical device is automatic.



The Brush Windmill Plant.

The tower, 60 ft. in height, is pivoted upon a single wrought iron gudgeon, 14 inches in diameter, which extends some 8 feet below the level of the ground in solid masonry. The tower as a whole, with its complete equipment of shafting, pulleys, belts, dynamo, etc., weighing more than 80,000 pounds, not only rests upon this gudgeon, but revolves about it as a vertical axis.

In the upper part of the tower is journaled the main wheel shaft of steel, 20 feet long and 6½ inches in diameter, with self-oiling bearings 26 inches in length. This horizontal main shaft carries the main drawing pulley, 8 feet in diameter, with a face 32 inches wide. A countershaft, arranged just below and parallel with the main shaft, carries three pulleys, the middle one receiving the main driving belt, while the two end pulleys are belted directly to smaller pulleys, one at each end of the armature shaft of the dynamo. The relative diameters of these different pulleys are such as to make the armature speed of the dynamo 50 times that of the mill wheel. The dynamo does not rest upon a solid support, but by a novel arrangement of counter-weights it is partially suspended by the two driving belts, only so much of its weight being allowed on the belts as is necessary to prevent them from slipping.

The dynamo, one of Mr. Brush's own design, is provided with an automatic switch to throw the machine into effective action when the speed reaches 330 revolutions per minute, and an automatic regulator which prevents the voltage rising above 90 volts at any speed. The working circuit is arranged to close automatically at 75 and open at 70 volts. The brushes of the dynamo rock automatically as the load changes. The field is slightly compounded. The normal electrical output at full load is 12 kilowatts, which requires the mill to develop at least 24 H. P.

The current generated passes to steel contact shoes, which slide upon annular plates surrounding the gudgeon as the tower turns with the changing direction of the wind, and thence by underground conductors to the storage battery in the basement of Mr. Brush's house.

The battery consists of 408 cells of 100 ampere-hours capacity, arranged in 12 groups of 34 cells each. These groups are charged and discharged in parallel. The containing jars are of glass, and the liquid in each is covered with a film of oil thick enough to prevent evaporation and spraying. The basement room containing the battery is a veritable electrical laboratory. The list of electrical instruments in daily use, besides the usual voltmeters, ammeters, switches, fuse blocks, etc., includes a series of potential indicators, one for each group of cells; an electrically operated switch, by means of which the current may be turned on or off the house mains by pressing push buttons in different parts of the house; a ground detector for the battery; a leakage detector for the different lamp circuits; and finally, and most ingenious of all, a compound relay which controls automatically, by means of varying hydraulic pressures, a powdered carbon resistance, placed in the charging circuit between the dynamo and the battery, which keeps the charging voltage practically constant. The house is supplied with 350 incandescent lamps, varying in candle power from 10 to 50 each, two arc lamps, and three fan motors. Current is also supplied to Mr. Brush's private laboratory. The plant has been in constant operation for the past six years, and it is found after continued use that the amount of attention necessary to keep it in working condition practically amounts to nothing.

An important feature of this experiment is the good behavior of the storage battery. Of the 408 cells in constant daily use, Mr. Brush informs us that not one shows serious signs of failure, and that all are in good, serviceable condition. He has never renewed a plate since the battery was first set up. One could scarcely ask for stronger proof of the ability of storage batteries to meet the requirements of this service.

Put a Penny in the Slot.

In response to Mr. Newman's toast, "Engineers' Views of Professors," at the Tenth Anniversary jollification of the Institution of Junior Engineers, Prof. W. E. Ayrton parried the bright sallies of the toastmaster in a way that only Prof. Ayrton could do. A good deal of fun was poked at professors in general in the toast, and every one knows that when he attempts to have fun at Prof. Ayrton's expense it is best to commence very early in the morning on a very cold day if he wants to escape without a blistered skin.

Prof. Ayrton's wit, however, was of a subtler kind on this occasion, which our English contemporaries seem not to have been able to grasp as yet, but give them time, and they will doubtless see the point eventually. As if the bright points of Mr. Newman's sallies were not sufficient, Prof. Ayrton came to his assistance (it is always unkind to help out another one's joke), and among other things read the following poem, which was written by a young lady—his ward—and also illustrated with pen and ink sketches of himself and Prof. Perry. We cannot reproduce the illustrations, which are good, but the poem speaks for itself sufficiently without them:

It is rumored that Ayrton and Perry
A wonderful system have got
For the teaching of practical science
By putting a coin in the slot.

A student arrives at the Central,
His mind an absolute blank,
Yet he leaves simply teeming with knowledge
Imparted by turning a crank.

While as for my eminent guardian,
I suppose all his labor has been
To pick up the showers of money
And pensively oil the machine.

Then bring us the laurel and myrtle,
And bring us the garlands of bay,
Let us crown the brave Ayrton and Perry
For showing so royal a way.

Let everyone go to that college,
Let us all drop our coins in and see,
If her guardian would but turn the handle,
How wise even Tina would be.

Church Illumination.

The Rich and Impressive Effects Produced by Electric Lighting in Some New York Churches.

Science and Art Join Hands in the Embellishment of Our Temples.

BY R. M. BERNARD.

The rapid advance made of late years in the application of electrical science to the lighting of public buildings, churches, etc., has directed the attention of architects to the subject, and the possibilities it offers insure thoughtful consideration for an article written for the purpose of calling attention to what has already been done in this direction, and hinting at what may yet be achieved by those who realize the great value of the omnipresent fluid for purposes of art, symbolism and decoration.

Our forefathers were satisfied with candle light for the simple reason that they could do no better; and just as when coal gas was superseding the dangerous and ill-smelling oil lamp it had many prejudices to overcome, so people have been timid about the adoption of electricity because of an imaginary danger which the uneducated supposed to underlie the use of this new, and to some minds uncanny force. In the last few years much has been accomplished to dissipate this feeling, and the popular mind is becoming gradually accustomed to the use of the electric light. Nothing, perhaps, has done more to educate the minds of the masses to the decorative possibilities of the electric light than its application within the last five years to the lighting of several of the largest churches in this city. The greatest advances in this new art of electrical church decoration must in justice be ascribed to Mr. D. Colombani, now secretary and treasurer of the Metropolitan Electric Equipment Company of this city. Five years ago Mr. Colombani was connected with the Edison Electric Illuminating Company, and had superintended the installation of electric lighting in many public and private buildings in the city. His early training and his favorite studies had inclined his mind to the subject of symbolical church decoration, and it was natural that the idea of applying electricity to this purpose should present itself to him. He succeeded, after considerable opposition, in obtaining the consent of the ecclesiastical authorities to light the Church of the Holy Innocents, West 37th street, with electricity, and this was accomplished just before Christmas, 1889.

GUARDIAN ANGEL, BAPTISTRY, IN ST. FRANCIS XAVIER'S CHURCH.

MR. D. COLOMBANI.

SYMBOLIC EFFECTS HEIGHTENED.

His efforts in this church were confined merely to providing an adequate and satisfactory substitute for the gas with which the church had theretofore been lighted, and in this he succeeded beyond the anticipations of all concerned. His artistic sense, however, was by no means satisfied with what he considered so meager a result as this, and it was only when he had obtained the consent of the Jesuit Fathers to decorate their magnificent church on West 16th street that he felt he was about to be afforded an opportunity of showing all that could be accomplished by the electric light in accentuating existing decorative features, and bringing forth in bold relief the symbols which are so important a feature of ecclesiastical architecture.

To Rev. Wm. O'B. Pardow, S. J., now Provincial of the American Jesuits, and at that time President of St. Francis Xavier's College, belongs the honor of appreciating the ideas presented to him by Mr. Colombani, and entering into them with such earnestness as to have rendered possible the accomplishment of what must be regarded as the parent of electric lighting as applied in its higher possibilities to ecclesiastical edifices. Father Pardow quickly recognized the advantages which would accrue to the church from the installation of the electric light, and, except for a few necessary limitations, gave Mr. Colombani carte blanche to go on with the work. He was rewarded when in May, 1892, he was able to realize that his progressive spirit had enabled the electrician to make his church the most complete electrically lighted place of worship in the world.

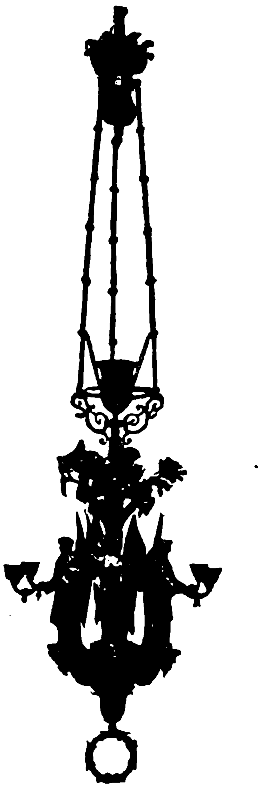
Following the installation in St. Francis Xavier's came in rapid succession the lighting by electricity of several other churches in New York and in Brooklyn, among which may be named St. Bernard's, on West 14th street; St. Agnes's, East 43d street; St. Francis d'Assisi, West 31st street; St. Joseph's, Washington Place; St. Gabriel's, East 37th street; Sacred Heart, West 51st street; St. Michael's, West 31st street, in this city, and the churches of the Nativity, St. John the Baptist and St. Thomas Aquinas in Brooklyn.

SPECIAL FEATURES BROUGHT OUT.

Each of these churches had its own peculiar features of architecture and of decoration to be considered in the installation of the electric light, and it is in his special treatment and attention to the particular requirements of each that Mr. Colombani has shown himself to be not only a skilful electrician but an artist. Born in Corsica, the island of genius, and reared amid the artistic and religious surroundings of Southern Europe, his intimate acquaintance with the symbols and ritual of the Catholic Church has enabled him to harmonize the mechanical part of his work with the ecclesiastical features which had to be emphasized, and has made it possible to overcome difficulties which must have proved insurmountable to an ordinary layman however skilful as an electrician.

In approaching the illumination of an altar or statue, or any special feature of a church, the artist always set himself the task of depicting by the aid of the electric lights the particular points upon which it was desired to lay emphasis.

For instance, in the lighting of the shine of the Sacred Heart, in St. Francis Xavier's, the idea sought to be presented was the love of Christ for man, and His victory over man's arch enemy, the Devil. That love was shown, as Catholic doctrine teaches, by His passion, death and resurrection, and His institution of the "sacrament of His love." This is typified in the scheme of illumination by a metal structure in the form of a grapevine, grapes and leaves being reproduced in the metal with faithful exactitude of color and form. In the center is a bunch of wheat ears. These are symbolical of the bread and the grapes of the wine of the sacrament. Intermingled with the leaves and branches of the vine are miniature lamps, wired eight in series, of the nearest form to that of a grape, and of various colors. The passion is symbolized by a passion flower vine running across the arch of the alcove, each flower and leaf being perfectly reproduced in hammered metal. Between the flowers and the leaves are small frosted candelabra lamps,



SANCTUARY LAMP, ST. JOSEPH'S CHURCH.

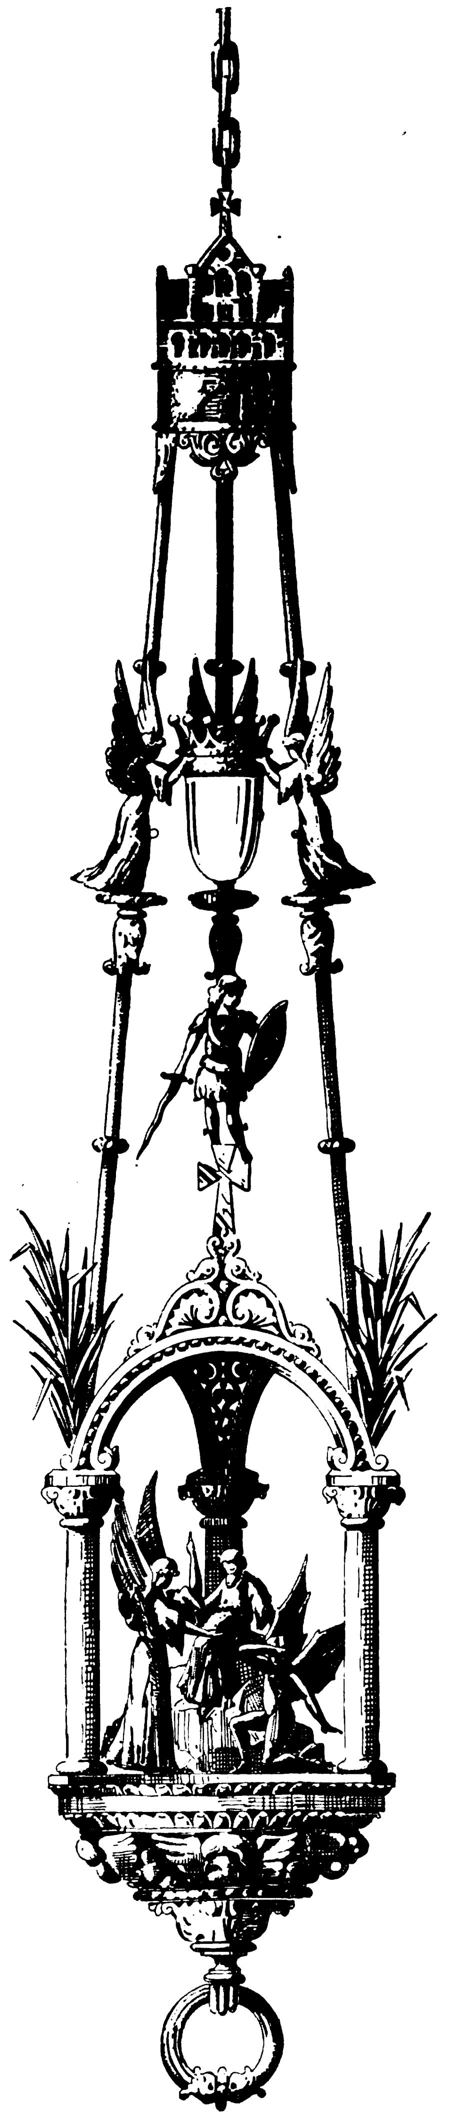
most appropriately made to correspond with the general artistic effect of the vine. These are wired two in series. Worshippers are reminded of the death of the Saviour by a cross composed of sixteen spherical 8 c. p. frosted candelabra lamps which surmount the outer edge of the alcove in which the altar stands. These lamps are wired two in series. The passion and resurrection are further symbolized by a large red rose on each side of the statue, in the center of which nestles a blood red 16 c. p. lamp. The victory of Christ over the Devil is shown by two fixtures fashioned of red hammered copper to represent palm leaves, the sign of victory. The lamps introduced among these leaves are 16 c. p. frosted bulbs. A beautiful effect is produced by an arch of thirty 16 c. p. lamps which are placed with a corrugated glass reflector behind them on the inner side of the coping of the arch. They are thus concealed from the view of the observer while they flood with their radiance the statue and the shrine below. This arch is wired in two circuits, which are connected with the switchboard in the sacristy, each switch controlling 15 alternate lamps. The idea intended to be conveyed by the arch is the omnipresence of God, who is watching over us at all times, though hidden from our view.

A BEAUTIFUL STATUE.

Another instance in which symbolism is admirably brought out in the same church by the electric light is in the bronze statue of the guardian angel designed by Mr. Colombani for the baptistry of the lower church. The beautiful tradition of the church is that a member of the angelic band is specially appointed to watch over the spiritual welfare of every soul that is born into this world, and that at the moment of baptism the regenerated mortal is handed over to the care of its guardian angel. In the treatment of the statue this conception is most artistically brought out. The figure of the angel is represented standing erect over the baptismal font with outstretched wings and looking with encouragement on the soul that has just received the rite of the church. In the right hand, which is just raised from the side, is held a small Pompeiian lamp whose weak flickering flame represents the still, small voice of conscience which the angel awakens in the soul of the Christian just aroused to a sense of its spiritual needs. The uplifted left arm pointed heavenward holds in the grasp of the hand a large 32 c. p. frosted lamp on a keyless socket, symbolical of the brightness of the glories of heaven to which the soul may attain if it hearken to the admonitions of its angel guardian. The contrast between the two lamps shows very effectively the progress in illumination since the days of the old oil lamp of the Romans.

In the altar of St. Aloysius, opposite the shrine of the Sacred Heart, the same miniature colored lamps which were used so effectively in the vines on the latter altar are again brought into play in producing the effect of jewels in the crown which two angels are represented placing on the head of the saint. Hitherto for work of this kind church decorators have had to depend on colored stone or glass which produces a dead and lifeless effect compared with the brilliancy of the tiny colored electric globes.

Before leaving the church of St. Francis Xavier there is one more thing which calls for remark, viz., the method used in lighting the pulpit. This is, perhaps, the most difficult problem which church illuminators have had to solve. In St. Patrick's Cathedral, for instance, the effect of the beautiful and artistic white marble pulpit is sadly marred by the inadequate means of lighting. The want of an electric plant in that magnificent pile has compelled the adoption of two gas fixtures—one at each side of the preacher. These produce a poor light compared with that of the electric current, besides causing a most inartistic effect by casting shadows in the most inappropriate places. The same trouble has been experienced in even a greater degree in the magnificent church of the Paulist Fathers in Fifty-ninth street. The gas jets not only fail to illumine the face of the preacher but also dazzle his eyes by their glare.



Sanctuary Lamp, St. Michael's Church.

In St. Francis Xavier's the presence of the electric plant suggested to Mr. Colombani an easy and artistic way out of the difficulty. From the front of the sounding board over the pulpit a silver dove is suspended as if flying toward the congregation with outstretched wings. In the back of the dove, hidden from view, is placed a 32 c. p. lamp with a reflector behind it which throws the light full on the face of the preacher, causing him no inconvenience and making visible to his hearers every slightest change of expression. Symbolism even in this small detail is not lost sight of, for the dove represents, of course, the Holy Ghost, the Spirit of Truth, casting his rays of inspiration into the heart of the preacher, as he sent tongues of fire upon the apostles on the first Pentecostal morning.

TRANSLUCENT ALABASTER PEDESTALS.

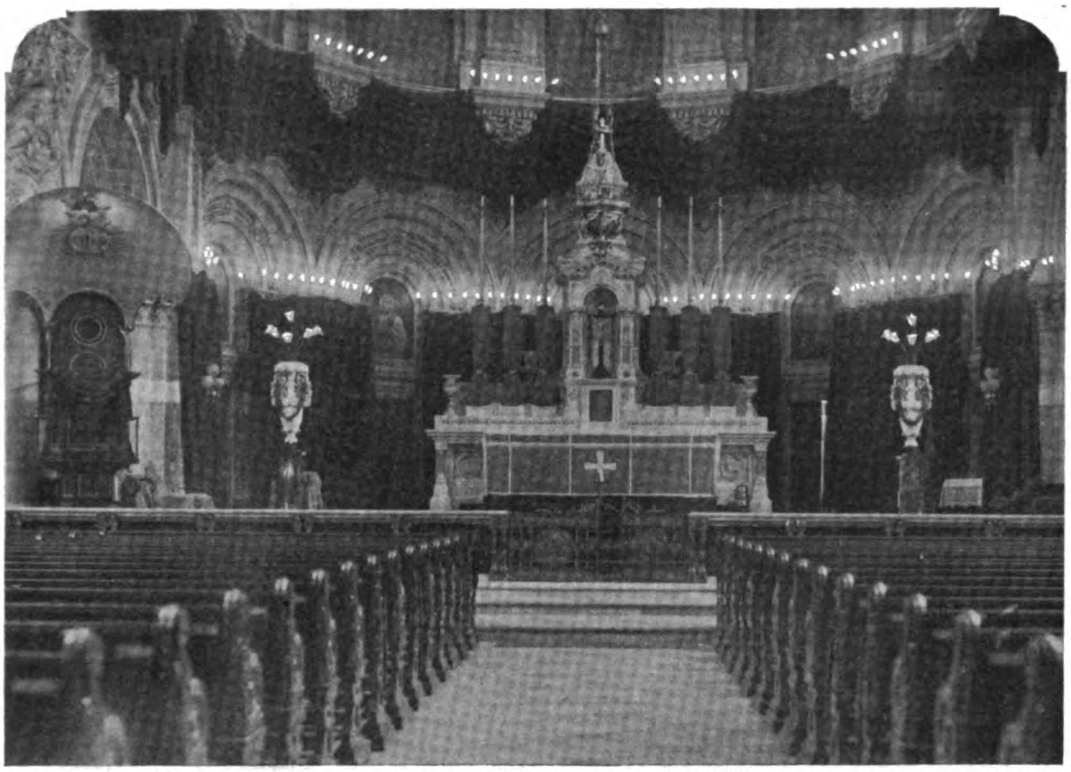
In St. Joseph's Church, on Washington Place, much difficulty had been experienced by the clergymen at the early services on dark winter mornings in consequence of their own shadows obscuring the faces of the communicants who had presented themselves at the sanctuary rails. This might have been overcome by affixing brackets with gas or electric lights to the columns at the ends of the railing, but this would have been inartistic and would have marred the general architectural beauty of the columns. The idea was conceived by the electrician of placing a hollow alabaster pedestal about four feet high at each side of the sanctuary, a few feet from the rail. These pedestals are each surmounted by a beautifully carved vase of about the same height. Six glass lilies of a delicate pink tint spring with carved metal foliage from the vases. A 16 c. p. lamp of a cylindrical pattern forms the stamen of each lily. A very beautiful effect is produced when the switch controlling the vases is suddenly turned on. The frosted stamina of the lilies show up in warm contrast to their pink petals and the electric lights in the hollow vases and pedestals penetrate through the transparent stone, causing the veins of the alabaster to show out in all their beautiful natural tints.

It is scarcely necessary to say that these pedestals and lilies have their symbolical significance as has all the church work of this artist. The pedestal is intended to represent the pillar of fire which led the Israelites through the wilderness, the vases are symbolic of the pot of manna, the heaven sent food of the chosen people, which was itself a type of the eucharistic bread of the new dispensation, and the lilies are types of the purity of heart expected from those who approach the table of the Lord.

The strictness of the rubrics in regard to placing anything upon the throne over the tabernacle in the center of the altars in Catholic churches has been a cause of great difficulty in throwing light upon the monstrance, the vessel in which the Host is exposed. In consequence, while each side of the altar blazed with lights the center, where the monstrance is placed, was always the darkest part of the altar, whereas to correspond with the spirit of the devotion it should be the brightest of all. To remedy this incongruity caused our artist considerable thought, but he finally hit upon a plan which would not conflict with the rubrics and yet produce the required effect. By placing six cylindrical 16 c. p. lamps behind the two front pillars of the four which support the throne, one at the base, one at the centre and one at the capital of each, he threw a perfect halo of light upon the monstrance.

THE GREAT CATHEDRAL MONSTRANCE.

This plan was carried out at St. Francis Xavier's, St. Joseph's, the Church of the Holy Innocents and several other churches, but could not be applied to the great ostensorium of St. Patrick's Cathedral, which on account of its great size has to be exposed on the table of the altar instead of being placed upon the throne. When this ostensorium was exhibited recently with the other works of art belonging to the cathedral, Mr. Colombani placed above and in front of the ostensorium a silver dove looking with outspread wings to the people and containing concealed in the back a 32 c. p. lamp with a reflector which threw its rays full on the magnificent and richly jewelled surface of the ostensorium. The dove was supported on a slender gilt rod conducting the electric wire which passed over and behind the sacred vessel.



SANCTUARY OF ST. FRANCIS XAVIER'S CHURCH.

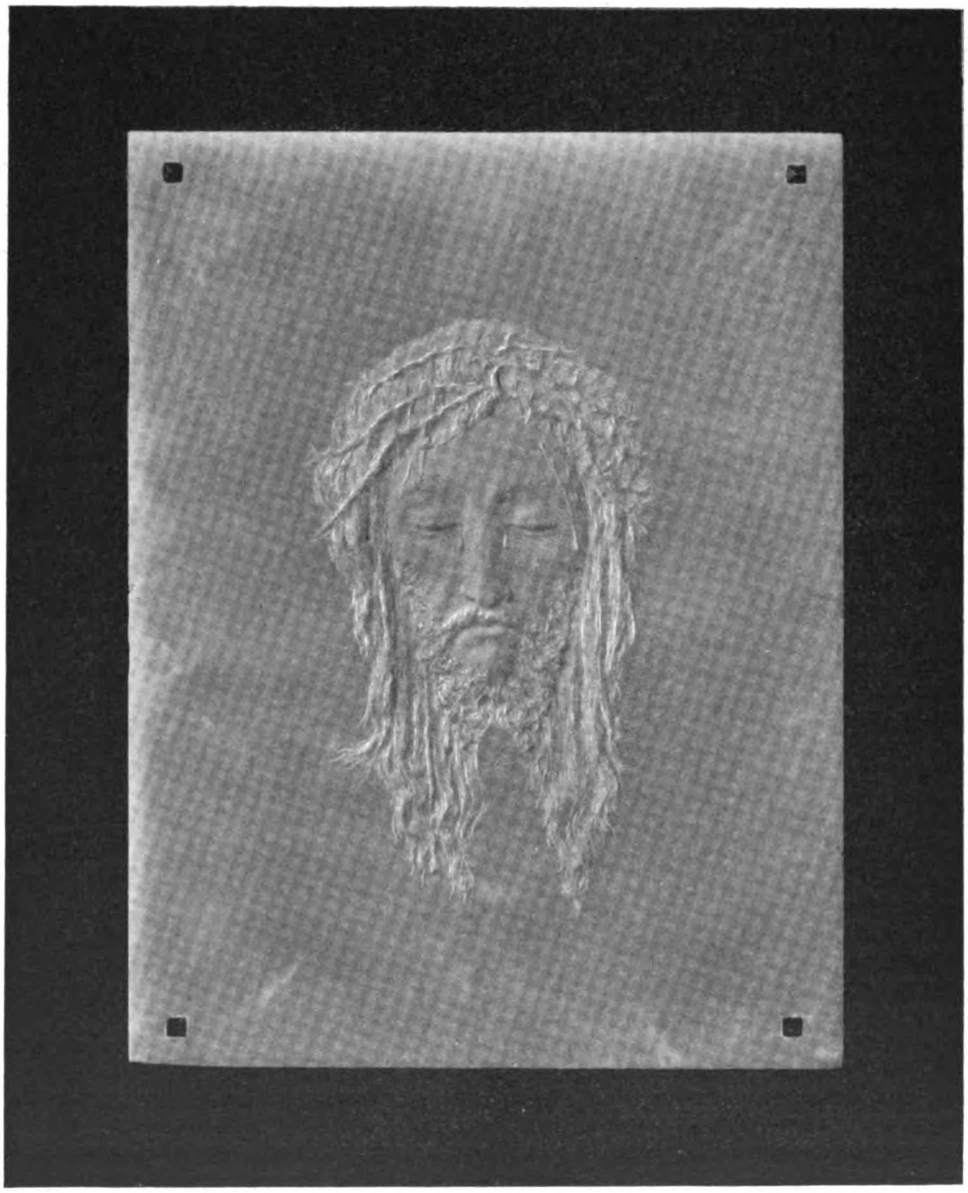
It being desired by the Confraternity of the Holy Face connected with the Church of St. Agnes, East Forty-third street, to erect a tablet emblematic of that devotion, it was found that on account of the chapel where the tablet had to be placed being situated beneath the gallery any ordinary means of lighting it would be totally ineffective. Electricity in the hands of our artist once again came to the rescue. He conceived the idea of having the image carved in bas-relief on a slab of white onyx the transparency of which would enable him to show the lineaments of the face by three 16 c. p. lamps with reflectors placed behind the slab. This was carried out and the effect is very beautiful. The tablet represents the apron of St. Veronica with which, as tradition relates, she wiped the bleeding face of the Saviour on the way to Mount Calvary, the apron afterwards retaining the impression of the countenance of the Man of Sorrows. The electric lights behind the tablet bring out in the clearest manner every line of the terrible, ghastly and pitiful face of the Saviour.

AN ARCH OF 160 LAMPS.

One of the most difficult achievements accomplished by our artist was the lighting of the immense painting of the crucifixion at the back of the high altar in the Church of the Holy Innocents. The only feasible way of effectively lighting the picture was by an arch of electric lights, backed by a corrugated glass reflector, hidden from the congregation, at the back of the coping of the great sanctuary arch. Difficulty followed difficulty in doing this work. The original plans giving the dimensions of the arch, which is 60 feet high, could not be found, and it seemed as if a scaffold would have to be erected to take new measurements. This was obviated by constructing the glass reflector on the principle of a fish's scales, so that it could either be expanded or contracted as might be found necessary. The row of lamps along the coping was erected in two sections on separate frames, which can be lowered for the purpose of replacing burnt-out lamps, by means of two rods which pass up through the ceiling of the church. In addition to these lights, there is a row of lights at the back of each of the columns supporting the sanctuary arch, and these are on flexible cords and may be raised and lowered by means of pulleys. Altogether, on the two columns and across the coping, there are 160 16 c.p. lamps controlled by three switches, one for the arc lights, and one for each of the columns.

A SPUR TO ARTISTIC DECORATION.

One noticeable effect of the application of electricity to church lighting has been the impulse given to improve the character of the other decorative features. For example, the rubrics of the Catholic Church ordain that before the tabernacle containing the blessed sacrament shall always be burned a lamp fed with pure olive oil, commemorative of the "perpetual fire" of Solomon's Temple and of that sacred mystic fire of divine charity with which the heart of the Saviour burns toward mankind. Before the advent of electric lighting, the general dimness of the churches made it a matter of



ONYX HOLY FACE, ST. AGNES'S CHURCH.

small importance what the character of the lamp (known as the sanctuary lamp) containing this oil might be. Now, however, that churches are brilliantly lighted, the general brightness puts to shame anything tawdry or inartistic, and several churches have sought to have designed for them sanctuary lamps which should be in harmony with their artistic surroundings and express symbolically some idea of the name given to the church in which they hang. Mr. Colombani has already designed and erected several sanctuary lamps which are something more than mere fixtures and have done much to elevate the artistic reputation of the churches in which they have been placed.

SYMBOLIC SANCTUARY LAMPS.

The sanctuary lamp in St. Joseph's Church, this city, represents the figures of the seven angels of the seven churches of the Apocalypse, each holding a candelabra lamp made to resemble when lighted a flame, typical of his guidance of the church under his care. These figures are grouped around the base of a tree representing the genealogical tree of St. Joseph as described in the first chapter of St. Matthew's gospel. At the summit of the tree is the red sanctuary light, typifying the fruit of the tree, which is "our Lord the light of the world." The height of the lamp is 12 feet. The figures of the angels are 2 feet high and are of solid bronze finished in gold plating. The use of the electric current gives to the whole lamp the appearance of massive gold. It weighs about 360 pounds, and is suspended by a steel cable plated with gold.

Soon after the erection of the sanctuary lamp of St. Joseph's, Mr. Colombani was commissioned by the two vicars-general of the archdiocese, Mgr. Farley, of St. Gabriel's, East 37th street, and Very Rev. Dr. Mooney, of the Church of the Sacred Heart, West 51st street, to design lamps for their respective churches, and both of these lamps are singularly beautiful examples of artistic church decoration.

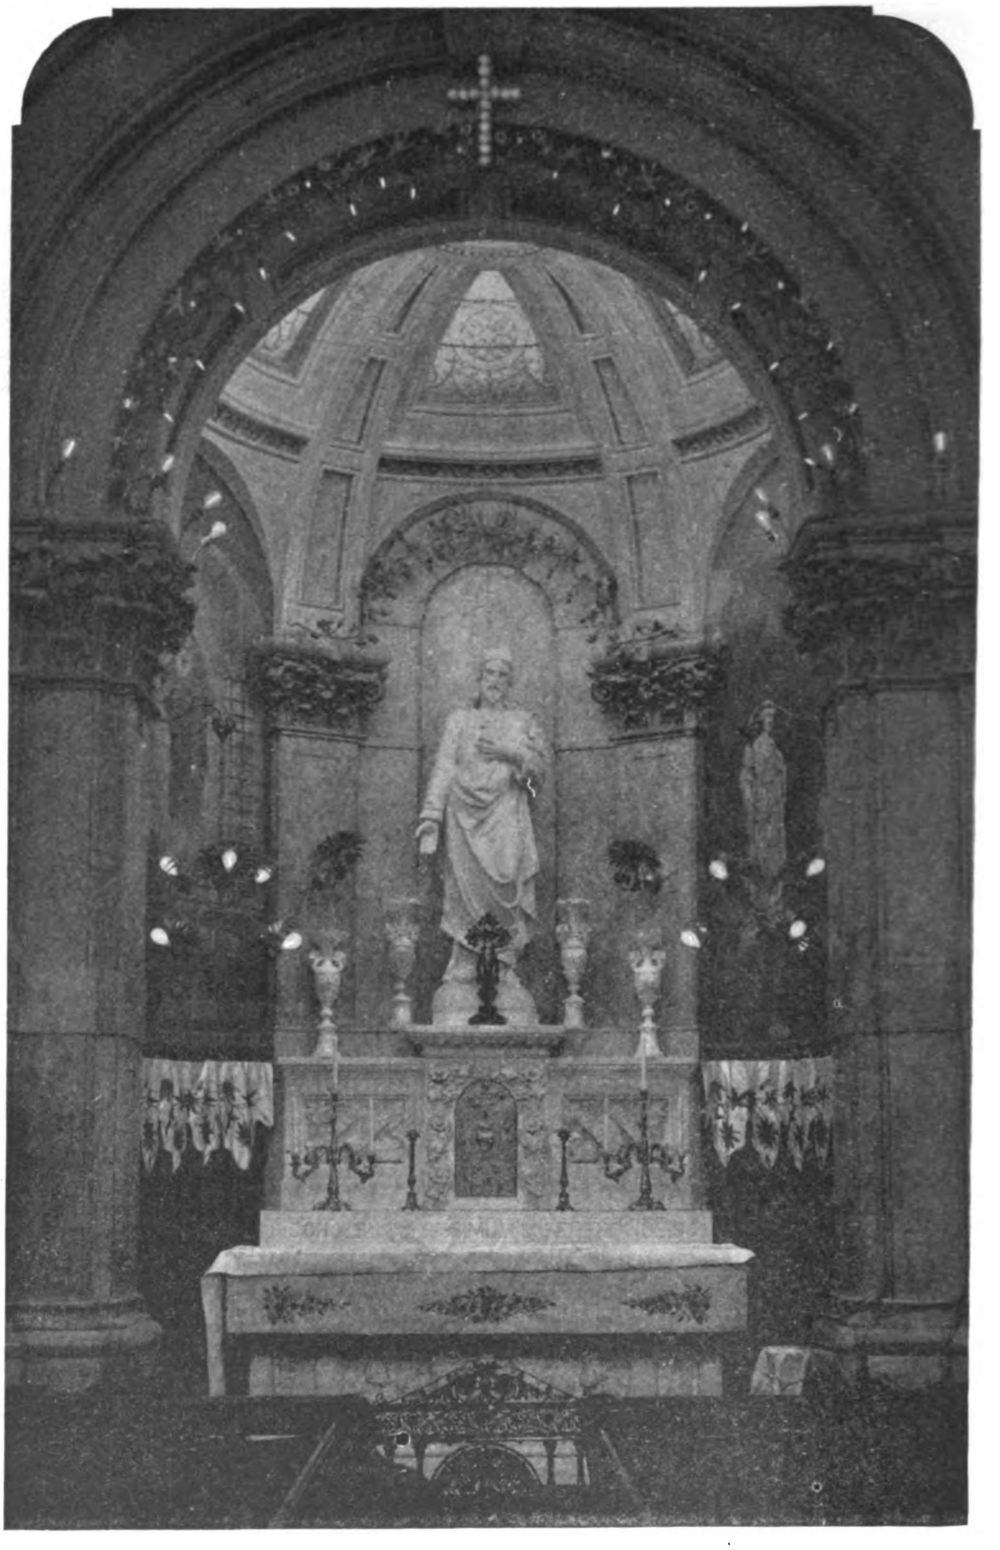
The lamp at St Gabriel's is one of the most striking features of the interior decoration of the church, which was renovated a few months ago so as to be almost a new building. Striking the eye immediately one enters the church, it reveals at once to the Catholic worshipper the fact that the angel Gabriel is the patron of the church. The lamp is cast of solid brass, and is 12 feet high and 22 inches wide at the base. The idea of the artist was that it should typify the patron saint of the church, and for this reason he has illustrated the various incidents in which St. Gabriel is related to have had intercourse with mankind. Thus, on the summit of the lamp is represented the castle of Susa, where the prophet Daniel had his vision of the ram and the he-goat interpreted by the angel Gabriel, who told the prophet that in answer to his prayers seventy weeks of years would be taken off the period remaining before the coming of Christ, or the Annunciation, which is represented by the angel Gabriel, the Virgin Mary and the Holy Ghost (in the form of a dove containing a 32 C.P. spherical lamp whose rays illumine the face of the Virgin).

Two lions are shown, to represent the meaning of the name Gabriel, "Strength of God." They also suggest the promise that God will deliver from harm those who watch and pray, as he delivered Daniel from the den of lions.

The artist has departed from the usual custom of having the lamp suspended from three or more chains, and has used but two, his idea being to remind the worshippers of the two captivities of the prophet Daniel, who was twice cast into a den of lions, and who received through the angel Gabriel the solemn promise of the accomplishment of the mystery, which the same divine messenger announced to the Virgin. This idea of the two chains led the artist unconsciously to a revival of one of the oldest forms of lamps used in the church, and which is not to be found in any church of modern times, though one or two examples may be seen in some of the oldest monasteries in Spain and Italy. It was the custom to suspend from a plain lamp, a disk or plate of silver or bronze, upon which was hammered out an image of the saint who was the patron of the chapel in which the lamp was hung. At the feet of the prophet Daniel, the Roman figures LXX, formed of 32 2 C.P. miniature lamps, eight in series, represent the seventy weeks of the prophecy.

Taking the motto of the Church of the Sacred Heart to mean, as it is usually interpreted, that the sacred heart of the Saviour is continually beseeching the uplifting of the hearts of men, the artist conceived the idea of this lamp from the verse of Jeremiah iii, 41: "Sursum corda," "Lift up your hearts," and the response, "Habemus ad Dominum." "We have lifted them up to the Lord." This lamp, like that of St. Gabriel's Church, is cast out of solid brass and is also 12 feet high. It is, however, spherical or bowl-shaped, and is 28 inches in diameter.

The main feature of the lamp is a statue of the Saviour pointing to his heart, illustrating the expression "Son, give me thy heart." There are seven attendant angels in a circle surrounding the feet of the Saviour, each holding in his raised hand a heart of hollow metal in which is hidden a receptacle on which is screwed a 2 C. P. candelabra lamp to represent the rays of faith which illumine the heart which the true Christian offers to the Lord. The number of angels represented is seven, the number mentioned in the Apocalypse as well as in many other sacred writings, notably in the Syriac liturgy of Philonexus, who mentions seven cohorts of angels.



SACRED HEART SHRINE. ST. FRANCIS XAVIER'S.

THE ARTIST'S MASTERPIECE.

The most recently designed lamp was that of St. Michael's Church, on West 31st street, and this may with justice be considered the artist's masterpiece. The subject, St. Michael, the defender of the Church of God, is so prolific as to have afforded an almost limitless field for the artistic employment of the electric light.

The scene pictured is St. Michael contending with the Devil for the body of Moses. This fact is represented by three figures, viz., the body of Moses, St. Michael and Satan. An electric candle is placed on each side of the body of Moses, which is on a rock in a recumbent position with the head inclined to the left. Satan is turning away from the spot, anger and despair being shown on his countenance. St. Michael stands erect delivering a message to Satan.

Pictorial Telegraphy—Fig. 1.

The two electric candles beside the body of Moses signify the cause of the dispute. The holiness and divinely brightened countenance of Moses were so pronounced that the Devil, knowing the idolatrous tendency of the Israelites, attempted to cloud all the brilliancy of worship with the darkness of idolatry and his own worship.

The hidden electric lights illuminating the group typify the providence of God, which watches us in doubt and shines upon us in the hour of our greatest darkness, the moment of death.

The vase of oil for the perpetual lamp is encased in the crown held by two angels, who were ordered to secretly bury the body of Moses. It brings to our minds Moses receiving his immortal crown through the anticipated merits of our Saviour, Jesus Christ, "The Light of the World," whose coming he foretold.

The bas-relief at the top of the lamp represents the apparition of St. Michael to the bishop of Seponto.

The miniature church is an exact copy of the Church of St. Michael in New York, which was remodelled in the year 1893 by the Rev. John R. Gleason, the present rector.

The cherubs' heads at the base of the lamp tell us of the holy office of the angels who assist us in our devotions, join their supplications to ours, carry up our prayers to God and bring back his blessings and gifts to us.

The palm branches at the base of the chains represent the triumph of Christ over the Devil.

The three rods holding the different parts of the lamp together bring to our minds the three holy archangels particularly distinguished in Holy Writ, who were God's ambassadors in the execution of his greatest designs—St. Michael, which name in Hebrew signifies, who is like God; St. Gabriel, the Strength of God, and St. Raphael, the Healing of God.

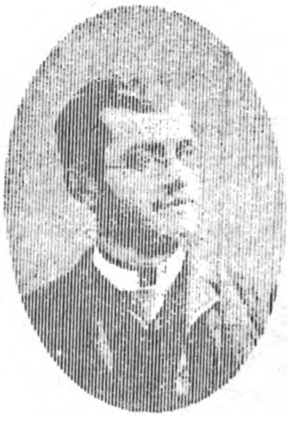
The ring is symbolical of God's eternity—without beginning and without end.

It also reminds us that man is the link between the spiritual and the material world, he being by his body allied to matter, and by his soul to the celestial intelligence.

In addition to its usefulness in illumination and decorative purposes, the efficacy of electricity as a motive power has been demonstrated in its application to the organs in several churches, notably in St. Patrick's Cathedral, St. Francis Xavier's, Grace Church, St. Thomas's Episcopal Church, St. James's Catholic Church, and in St. Peter's, the oldest Catholic church in the city.

There are many advantages connected with the use of an electric motor for pumping air into the bellows of an organ. When steam or hydraulic power is used the wear and tear are found to be very great in consequence of the incessant action of the machinery.

In recounting in this article what has already been accomplished in the application of electricity to the lighting and decoration of churches, our object has been to suggest to our readers its possibilities in the future, as much as to record its successes in the past. If so much has been done in the short space of a lustrum, what great triumphs may we not reasonably expect in the years to come?



Pictorial Telegraphy—Fig. 2.

Popular Electrical Science.

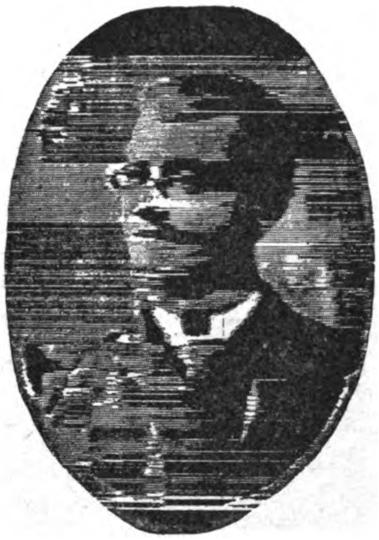
PICTORIAL TELEGRAPHY.

BY NELSON W. PERRY, E.M.

In the issue of Electriciy for Nov. 18th, 1891, we published a memorable article entitled "Pictorial Telegraphy," in which was described the electro-artograph of Mr. N. S. Amstutz of Cleveland, O., by means of which half-tone reproductions of photographs could be automatically transmitted over an ordinary telegraph wire and automatically reproduced at the further end. It was our good fortune at the time to be able to present specimens of the work in that stage of

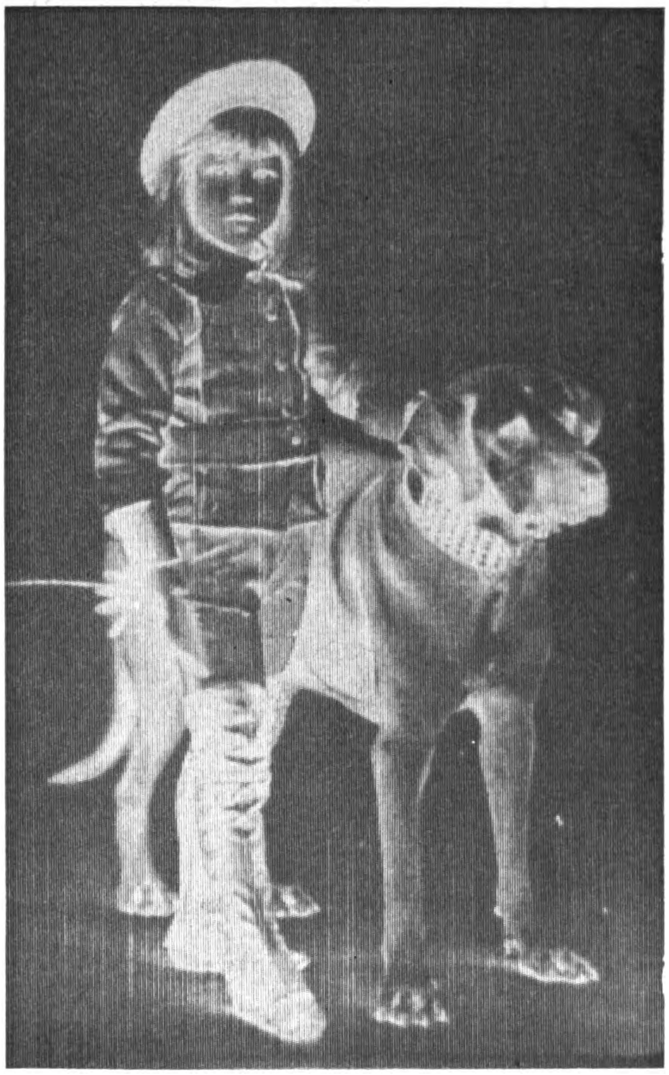


Pictorial Telegraphy—Fig. 3.

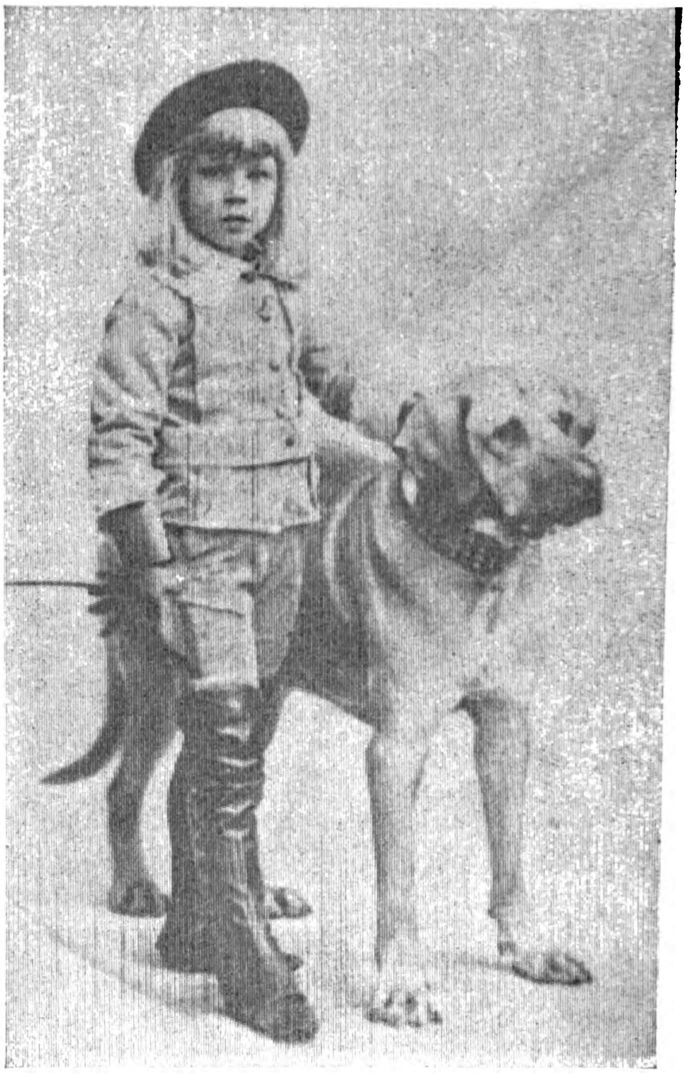
Pictorial Telegraphy—Fig. 4.

the development which had been sent over a single wire 20 miles long with a 110 volt current. These pictures were necessarily crude and it was with great difficulty that we persuaded the inventor to permit of their reproduction, but he finally yielded to our importunities and the result was that the article and pictures were copied by the press in every civilized country on the globe.

Commenting upon the process at the time, we said: "The illustrations which we present are not valuable from an artistic point of view, but we think they will be better appreciated by our readers than more finished productions would be, in that they show the operation of the process better. It is not often that an inventor is willing to have his first and crudest efforts published, and thus much of historical interest is often lost to the world. The avidity with which the first attempts of great inventors are sought for in after years attests to the interest they have for the public, and we think Mr. Amstutz is wise in permitting the publication at this time of the crude reproductions of his first experiments."



PICTORIAL TELEGRAPHY—FIG. 5.



PICTORIAL TELEGRAPHY—FIG. 6.

Three years and three months almost to a day have elapsed since the original publication, and we are now able to revert to this process again with feelings of pride and satisfaction in the results accomplished in that short period. No longer is it necessary to say that "the illustrations which we present are not valuable from an artistic point of view," but instead, we may now say, "they are artistic in a high degree," and the beauty of the work is only heightened by the contrasts of the accomplishments then and now.

The present occasion seems singularly opportune for this second article on this practically new art, since it is the occasion of the meeting of the National Electric Light Association at the home of the inventor, and no class of men will take more pride in the new achievements of electricity than that engaged in its commercial production.

A BRIEF DESCRIPTION OF THE PROCESS.

Alexander Graham Bell found that by varying the strength of an electric current in consonance with sound waves he could transmit articulate speech nearly to the ends of the earth.

Edison, Taintor and Bell found that by causing a stylus attached to the center of a diaphragm to which words were spoken to bear lightly upon a revolving wax cylinder they could engrave upon that wax and preserve for all time the characteristics of those words—the undulatory graved line in the soft matrix became the mechanical fac-simile of articulate speech, which required merely a reversal of the process to reproduce the original sound waves. If the diaphragm stylus were allowed to trip over the undulatory graved line it would give out spoken words. If it were caused to vary the strength of an electric current those undulations might be reproduced in sound at a distant point in a telephone receiver, or, by causing this current to actuate an electro-magnetic device, a duplicate engraved record could be made in wax at the distant point which could be made to utter again the original words.

The phonograph inscription is the mechanical record of sounds. Can we make a mechanical record of light in all its various gradations? Certainly, and quite as simply.

Many substances undergo changes of solubility which are proportional to the intensity of the light to which they are exposed. One such substance is ordinary gelatine in which is dissolved a little bichromate of potassium. This, when exposed to the action of light, becomes insoluble in warm water, whereas before such exposure it will be dissolved away. If, therefore, we expose such a plate beneath a photographic negative, those portions which are exposed to the strong light will become totally insoluble; those that are entirely shielded will remain soluble; and those affected by the subdued light—the half tones—will have their solubility affected in proportion to the amount of light received. It remains now only to sponge the plate with warm water to have a photograph in relief wherein the high lights will have the greatest elevations and the shadows will be depressed.

If now this relief photograph were rolled upon a phonograph cylinder and placed upon the machine, its stylus describing a fine spiral path would rise and fall as the picture passed beneath it just as it does when following the phonogram. It is not sound, however, that is wanted in this case, but another record at a distance, so Mr. Amstutz causes this rising and falling of the stylus as it passes over the relief photograph to vary in similar manner the strength of an electric current. This undulatory current passing over an ordinary telephone or telegraph wire actuates a similar stylus at the further end which, bearing upon a revolving wax cylinder, engraves in the wax an exact reproduction in elevation of the path over which the first stylus has passed. From this cylinder an electrotype may be taken, flattened out and placed upon the press, and it is from such that the illustrations herewith produced were made.

The graving tool is made V shaped so that as it cuts deeper it cuts wider, and in printing produces blacker lines.

If we follow the process we see that the relief photo in gelatine printed from a negative is a positive. This may be reproduced at the distant point either as a positive or as a negative. Both forms of reproduction are shown to better illustrate the process.

Fig. 1 is a reproduction from a photograph by the ordinary half-tone process of a portrait of the inventor of the artotype, Mr. N. S. Amstutz. Fig. 2 is a reproduction from the same negative made by Mr. Amstutz last summer by the artotype process. To better illustrate the progress of the art since our first description we give Fig. 3, which is a reproduction of a portrait of the same gentleman made in 1891 and printed in our issue for November of that year. The principles involved in both are the same, but the mechanical execution is far more perfect in the later than in the earlier work.

Through the kindness of Mr. Amstutz we are also able to give another series of cuts illustrating the art which are exceedingly interesting.

Fig. 4 is a half-tone reproduction prepared by ourselves of little Lord Fauntleroy and his dog. From the *same original* were produced Figs. 5 and 6—these by the electro-artograph. Fig. 5 is a negative reproduction such as before referred to. In this the marks of the graving tool give prominence and everything is reversed—viz., the portions of the lines which in the positive print black here print light, and vice versa. If this were printed in white ink on a black background the lights and shadows would come out in their proper relations. The ordinary ferrotype pictures are reproductions of a similar kind, and the writer possesses a picture from this same cut printed in silver on a black card. The effect is superb and resembles a photograph on white satin. Fig. 6 is a positive from the same original and shows the finished results obtainable after telegraphic transmission over a single wire.

These last two reproductions are made from engravings having 80 lines to the inch. The half-tone from the original (Fig. 4) is made with 120 lines, and shows finer gradations of light; but these effects are entirely within the compass of the electro-artograph, as it has recently been constructed to produce the same fineness of lining, and the writer received too late for reproduction in this article a sample of such work which is beautiful in the extreme.

For ordinary newspaper reproductions, however, this extremely fine work of 120 lines to the inch is not desirable, since the delicate effects are all lost in hasty presswork and poor paper.

But the great utility of this process lies in the fact that it is almost entirely automatic. The relief photo must, of course, be prepared and wound on the cylinder by hand, and the machines at both ends of the line started up, but the tracing of the transmitting stylus and the engraving on the receiving cylinder proceed without further attention.

As to the time occupied in this operation, Fig. 3 was transmitted and engraved in 10 minutes, while Figs. 5 and 6 occupied only 3 minutes' time.

In conclusion I will say that Figs. 5 and 6 were made from electrotypes from an original engraving marked "F," deposited with the Smithsonian Institution at Washington, D. C.

The plans for building a net of electric railways for the city of Vienna, Austria, are approaching completion. The new tramway company has quite lately made trials with motors worked by accumulators, and is now intending to give up working with horses altogether. An electric tramway is in course of construction at Nice, and is expected to be completed by March 1. This line will be used by Her Majesty Queen Victoria, who is expected to arrive there on the 15th of that month.

According to the London *Electrical Engineer* no less than 284 fires were caused last year in the city of London by what are termed gas explosions, but not a single conflagration has been traced to the electric light.

The Lighting of Cleveland.

BIRTHPLACE OF THE ARC LAMP.

New Plant of the Cleveland Electric Illuminating Company.

Attendants at the Cleveland meeting of the N. E. L. A. who are making their first visit to that city will be surprised when they observe that Cleveland is the poorest lighted city of its size in this country, if not in the world.

There are several reasons for this condition of affairs, chief of which is the intermingling of the gas interests with the political powers.

Whatever may have been the shortcomings of the previous electric lighting companies, the rulers of the city now have no further excuse for delay. The new station, now nearly completed, equipped with apparatus for every kind of service, is able to supply current anywhere within the city limits economically and with a guarantee of good service.

The local Brush company of that city was one of the earliest commercial ventures in the line of arc lighting, the company being organized in 1881. Here was tried for the first time on a large scale the experiment of lighting a large city by means of towers. The towers adopted were different from those now in use in Detroit and other cities, consisting of a single standard built of short sections of tubing of large dimensions. The first one erected was in the public square, 256 feet high, having 8 4,000 C. P. lamps, requiring 18 amperes. Afterwards three others were erected in the central part of the city. The idea was proved to be a failure. Three of the towers have been taken down, and the fourth lowered to 150 feet in height, carrying 8 lamps of 2,000 C. P.

Five years later, in 1886, a Thomson-Houston company was started equipped with series arc, alternating and low tension incandescent apparatus.

In 1893 these companies were consolidated, the new company taking the name of the Cleveland Electric Illuminating Co.

To show the poor headway made by the two earlier companies in lighting the city, nothing speaks more plainly than the bare figures. Out of 540 miles of streets in the city only 18 miles are supplied with electric lights. There are apparently no obstacles in the way of extending this service to the limits of the city except politics and the pull which the gas people enjoy. The longest line required would be not over six miles from the new station.

It is to be hoped that the public spirited citizens of Cleveland will imbibe some of the prevailing enthusiasm over electric lighting matters this week, and that the city will not be compelled to rest forever under the proven charge of being far behind other cities in adopting the modern lighting system of the civilized world.

The station has been planned with great care under the direction of Mr. Robert Lindsay, who had several years' experience in one of the best conducted lighting stations in the world—that of the Brooklyn Edison Company. The arrangements are the result of careful study of the best American and European practice, and when completed it will rank with the best in this country or abroad. It is designed for high tension series arc, alternating current lights, low tension lights and power.

The building, 135 ft. long and 97 ft. wide, is located on Canal street, and extends back to the Valley Railroad. The Cuyahoga River is about 200 ft. from the rear of the building, the railroad being between the river and the building. A curved siding from the tracks of the Valley Railroad parallels the entire length of the boiler room side of the building.

The boiler room and engine room are 36 ft. clear between floor and roof trusses, while the front part of the building is 3 stories high.

The second floor is the dynamo room and is 18 ft. above engine room floor. This room is about on the level with sidewalk line at the front of the building.

The third floor, or workshop storeroom, is 20 ft. above dynamo floor and has a clear headroom under roof trusses of 12 ft. The engine room and boiler room are separated from each other by a fireproof wall extending up to the roof line. There are two Yale & Towne cranes in the plant, one in the engine room of about 28 ft. span and having a capacity of 10 tons, supplied with two geared trolleys and hoists. The dynamo crane has a span of 26 ft. and a capacity of 6 tons with single trolley and hoist. These cranes travel the entire length of engine and dynamo rooms, and are capable of handling any part of the engines or dynamos.

The general idea of the location of the machinery was to place the engines, boilers, and dynamos in such position that the loss of transmission of the different forms of energy from the coal to the line was to be the least possible.

BOILERS.

The boilers are four in number and of the Climax vertical type, three of them being rated at 800 H. P. each, and one 500 H. P. on 30 lbs. evaporation of water per hour. They are built for 200 lbs. working pressure, and are provided with individual dampers. Space has been left in boiler room of present building for two additional 800 H. P. boilers.

COAL AND ASH HANDLING APPARATUS.

The coal is dropped from the bottom of the hopper cars on the siding into a pocket under same, and delivered inside the wall of the boiler room basement. By means of valves on inside of building, the coal is delivered to the coal handling apparatus, and transferred to coal storage at the extreme end of the building, or directly to individual coal hoppers between the boilers in boiler room. This coal storage is placed about the base of steel stack, and is of the same height as the building proper, i.e., about 43 ft. The ashes are removed by means of the same apparatus as used for handling the coal. While hoppers are provided under each boiler, with valves, etc., necessary for holding a day's run of ashes, an ash storage is formed at the extreme southern end of building for receiving ashes until such times as they can be removed by carts drawn under the storage, and the same emptied by means of valves opening into either carts or railroad cars.

The steel stack, built by Riter & Conley, of Pittsburgh, is 226 ft. in height above stack base, and is 25 ft. 6 in. in diameter at cast-iron base, and 11 ft. 6 in. clear inside of brick lining at top. This stack is of sufficient capacity to take care of any increase of plant which can be located on the property. It is built of steel plate $\frac{7}{16}$ in. thick at the bell base and diminishes in thickness until the top plates are reached, which are ¼ in. thick. The steel shell is lined its entire height with a tapering brick lining, started 21 in. thick at the bottom and tapering to 4½ in. thick at the top.

There are three McIntosh & Seymour tandem compound vertical belted engines for driving shafting of arc and alternete-current generators. The engines have 19 x 36 x 24 cylinders, and develop 750 H.P. each at 125 lbs.. 150 revs. condensing. There are also two cross compound vertical condensing engines of the same make having 2 200 K. W. General Electric multipolar generators connected direct to each engine. These cross compound engines have cylinders 20x36x34, developing 800 H. P. on 125 lbs. steam, 150 revs. condensing. These engines are of the makers' latest type, having piston valves with

(*Continued on page 75.*)

THE HOME OF "ELECTRICITY."

Editorial Room.

Publisher's Office.

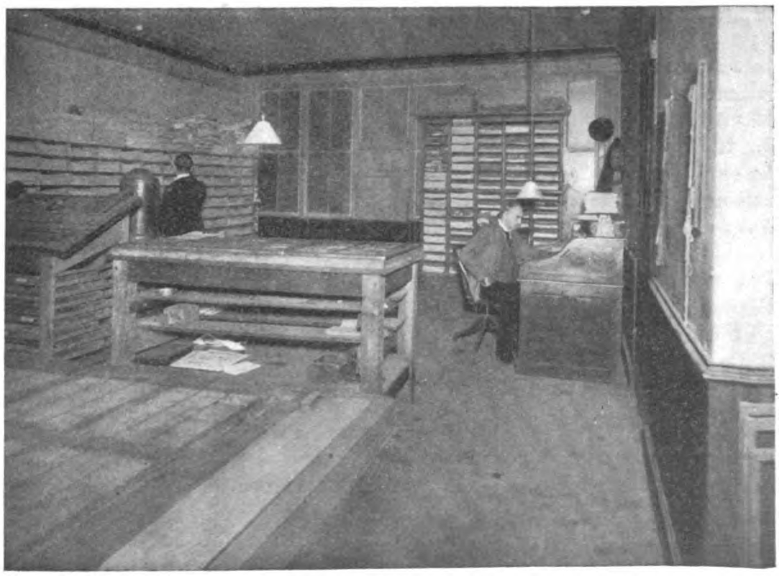
"Electricity's Home."

We do not think we are assuming too much in taking it for granted that the thousands of friends which Electricity has made in its brief and successful career are interested somewhat in the people who make the paper, and in having laid before them a view of the offices which have been its home.

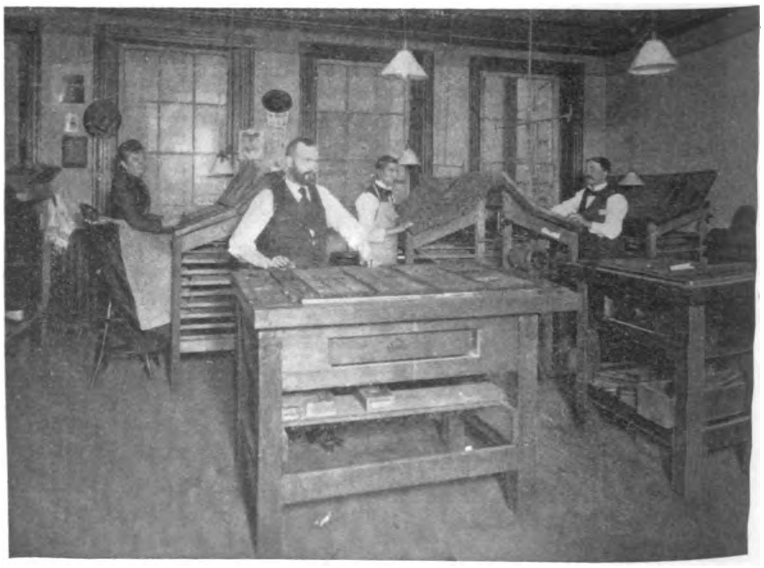
As is well known, Electricity's views of the entire newspaper question are different from most other people's in the same line of business. We have different views of the kind of offices which are fitted for good newspaper work. Hence, instead of choosing a show place, where comfort and convenience must give way to mere display, the present management chose a location where *work* could be done to the best advantage. Our home is, at the same time, convenient to reach for those who want to see us, and there is always an easy chair and a good cigar at the disposal of the man who has a good news story to tell. If the story be an extra good one, the visitor may be invited to lunch in the hostelry of John Rogers, on the next floor below. Just far enough from Broadway to avoid the procession of idlers, and just near enough to be still in the swim, at No. 6 Park Place, our friends can always find us.

As will be noted from the accompanying illustrations, Electricity possesses a composing room of its own, where all the type is set and forms made up, thus enabling us to take the news twelve hours later than any of our contemporaries; and if there is one feature of Electricity which, more than any other, has contributed to its pronounced success, it has been the feature of giving ALL THE NEWS up to the hour of going to press.

Counting Room.



File Room.



Composing Room.

(*Continued from Page 73.*)

riding cut-off on high pressure cylinders, and gridiron valves on the low pressure cylinder, and governed by means of shaft governor. All bearings and slides are water-jacketed, and the engines of heavy and well-balanced design.

PIONEER HUSTLERS—H. WARD LEONARD.

CONDENSERS.

Each engine has its individual condensers, there being five Worthington duplex 12x15x15, but so arranged that either engine can be thrown on either condenser.

The steam pipe between the engine and boilers is arranged to be as direct and simple as possible, with as little drop in pressure, and at the same time to take care of all expansive strains. The valves on the entire plant are Chapman gate valves. On the steam lines they are extra heavy ribbed shells, outside screw and yoke, bronze seats, and tongued and grooved flanges.

The exhaust pipe is entirely of flanged cast iron, as is also the discharge pipe and a portion of the injection pipe. The exhaust and discharge mains are 24 inches in diameter. The injection main is 18 inches in diameter, and is arranged so that an additional main can be put up for future plant. In the branches from engine exhaust to exhaust main 14 in. relief valves are used and the plant arranged so that it can be operated condensing or non-condensing at any time in case of necessity or emergency.

The injection water is taken from the cold well located on inside of building with a lift of about 10 ft. This well is connected with the Cuyahoga River by means of a 24 in. cast iron inlet pipe. The outboard end of this pipe is connected with a 10x10 x10 ft. crib sunk in river and secured by means of piles driven in river bed. The 30 in. cast iron discharge pipe extends from building to river, as well as the 8 in. cast iron blow-off pipe. These pipes were laid under the entire tracks of the Valley railroad.

PIONEER HUSTLERS—J. H. REID.

A 3,000 H. P. Hoppes heater is used for heating the feed water for the boilers. The feed pumps are placed in the basement but operated from boiler floor by the fireman. The pumps take the water from the heater and deliver it to boilers through feed lines or blow-off lines if necessary.

There are fourteen 125-light Brush generators of latest type with automatic regulators for arc lighting, two No. 60 Edison bi-polar generators for low tension direct current light and power, two T.-H. alternators of 1,000 lights capacity each and one of 4,000 lights capacity for incandescent lighting.

PIONEER HUSTLERS.

BRIEF SKETCHES OF EARLY ELECTRICAL SALESMEN.

The Men who Compelled the Business to Grow.—1879-1886.

R. J. Randolph.

Mr. Robert J. Randolph was born in Buffalo, N. Y., January 3, 1847. He went to Chicago in '65, and moved from there to Rockford, Ill., in '75, remaining in the latter city about eight years. While in Rockford he was a member of the Board of Aldermen, and during a portion of that time was vice-president of the Winnebago County Republican Central Committee. His first experience in the electrical business was with the Vandepoele Electric Company, being one of its first salesmen, having entered its employ shortly after Vandépoele moved from Detroit to Chicago, in '78. He sold some of the first machines that the Vandepoele Company ever built, some of which are running today; in fact, the first machine the Vandepoele Company ever built, five lights capacity, sold to the Rockford Bolt Works, Rockford, Ill., is still there. Shortly afterward, when Vandepoele succeeded in building a machine of fifteen lights capacity, Mr. Randolph sold one to the Nelson Knitting Company, Rockford, Ill, which is still in service. Early in the '80s he became connected with the Excelsior Electric Company, with which company he has been ever since, excepting about two years, when he went to Cincinnati and took charge of the Municipal Lighting, Power and Mining Department of the General Electric Company's Cincinnati district. Last year he returned to the Excelsior Company and opened headquarters at No. 5191 Monadnock Block, Chicago, Ill. Mr. Randolph is also president of the Akron and Cuyahoga Falls Rapid Transit Company.

F. S. Terry.

Mr. Franklin S. Terry was born at Ansonia in 1862. After passing through the High School there he entered the employ of Wallace Bros., and began his active business career in charge of the books of the Electric Supply Company in 1880. In 1884 he was sent to Chicago to open the branch in that city, which rapidly grew to be the largest supply house in the West or in this country. He was one of those most ardently interested in the organization of the N. E. L. A. Owing to lack of working capital, and through no fault of Mr. Terry's, the Electrical Supply Company (then called the Ansonia Electric Company) was forced to suspend, following closely upon the failure of the firm of Wallace & Sons at Ansonia. Mr. Terry is now identified with the Sunbeam Lamp Company of Chicago, which he and his brother, A. S. Terry, founded some years ago.

Charles D. Shain.

Mr. Charles D. Shain was born in Philadelphia, November 8, 1855, son of Charles J. Shain of the firm of Knox & Shain of Philadelphia, who were the first manufacturers of telegraphic instruments in the United States. He was graduated from the Central High School in 1872, and commenced business experiences with H. P. M. Birkenbine, hydraulic engineer. Afterwards he was engineer for the Johnson and Somerset Railroad Company, and later assistant engineer in charge of construction on the Jefferson division of the Texas and Pacific Railroad Company. In 1874 he was engineer for R. J. Dobbins, contractor for the Centennial buildings in Philadelphia; in 1880 superintendent of a silver mine in Arizona for the New York Mining Company. In 1881 became assistant engineer of the Toledo, Cincinnati and St. Louis Railroad Company, and in 1882 chief engineer of the Burlington and Ohio Railroad Company. Early in the year 1883 Mr. Shain entered the electrical field, being connected with C. C. Warren of the United States Electric Lighting Company at the time that company opened its Chicago office. In the latter part of 1884 was Western agent in the sale of incandescent lamps and supplies for the electric light department of the Union Switch and Signal Company. In 1885 was again connected with the United States Electric Lighting Company, and became assistant manager of the Western office. In 1889, after the purchase of the United States Electric Lighting Company by the Westinghouse Electric and Manufacturing Company, he became general district agent for the latter company at Cincinnati. In the fall of 1889 became connected with the United Edison Manufacturing Company in New York, and later became assistant general manager to H. Ward Leonard, general manager. In the summer of 1890, at the time of the formation of the Edison General Electric Company, was made Eastern district manager, filling this position until the fall of 1892, when the consolidation of the Edison General Electric Company and the Thomson-Houston Electric Company having taken place he resigned his position and opened an office at 136 Liberty street, New York, as a manufacturers' agent, representing the Weston Electrical Instrument Company, the Siemens & Halske Electric Company of America the Carpenter Enamel Rheostat Company, the Cutter Electrical and Manufacturing Company, and the Sunbeam Incandescent Lamp Company.

R. T. McDonald.

Mr. Ronald T. McDonald, who is now the president of the Fort Wayne Electric Corporation, could not be left out of the list of the early and successful salesmen, for it is only a few years since he was hustling in the sale of apparatus and the organization of new companies.

Mr. McDonald is believed to hold the record as the most successful individual salesman in the field, though in volume of business done Mr. Chas. D. Shain would be a very close second. Mr. McDonald is 46 years old, has a creditable record as a soldier, having entered the service as a drummer boy when a lad of only 13 years. After a successful commercial experience, he entered the electrical field in 1882, being one of the incorporators of the Fort Wayne Jenney Electric Light Co., and at the same time he assumed the management of the business. Since that time he has been very much in evidence, and always sticking closely to the Fort Wayne interests. The coup which resulted in his withdrawal from the General Electric Combination and the establishment of a new company upon an independent basis is matter of recent history and has not been forgotten. Mr. McDonald is probably the hardest worker in the trade to-day, and there seems no limit to his energy.

—

H. Ward Leonard.

Mr. Leonard was born in Cincinnati, O., February 8, 1861. After leaving the High School, he worked for two years as machinist in the railway shops of Cincinnati, and then went to the Massachusetts Institute of Technology, where he took a course in mining engineering. Graduating in 1883, he secured a position with Mr. Edison, became one of four selected by him as a staff of engineers to erect stations in this country. Two years later Mr. Leonard accepted a position as electrical engineer to install Edison's stations in Ohio. In 1887 he went to Chicago as general superintendent of the Western Edison Light Company. Two years later, as senior partner, he started the firm of Leonard & Izard. In 1889 Mr. Leonard accepted the position of general manager of the United Edison Manufacturing Company. Later he became manager of the light and power department of the General Electric Company, which position he occupied until September 1, 1891, when he resigned. He is now engaged in some important engineering work.

—

J. H. Reid.

Mr. J. H. Reid was born in Auburn, N. Y., in 1856, and started in the electrical business in that city in the fall of 1878 as a general construction man on the Edison Telephone Exchange. He installed the exchange at Lockport, N. Y., in 1878. In 1880 he became connected with the Empire State Telephone Company as foreman of construction. In 1885 he entered the United States Electric Lighting Company's Chicago office, remaining there until the summer of 1886. In 1886 he took the Western management of the Mather Electric Company's business, with office in Chicago. Afterwards Mr. Reid entered the employ of the Electrical Supply Company of Chicago, and was one of the active men in forming the N. E. L. A.

—

George H. Bliss.

Mr. Geo. H. Bliss was born at Worcester, Mass., May 12, 1840. He became a paper telegraph operator in 1858, at Dixon, Ill., on the Chicago and Galena Union Railroad. In 1864 he was made superintendent of telegraph of all the lines on the Chicago and Northern Railway. In 1877 he entered into a partnership with L. G. Tillotson & Co. of New York, forming the firm of Bliss, Tillotson & Co. which operated at Chicago. This was the first electrical industry of importance at Chicago. The concern was burned out in the great Chicago fire of 1871, losing $50,000 and recovering only $15,000 of insurance. In 1872 he bought out his New York partners and reorganized the business under the name of Geo. H. Bliss & Co. This concern was burned in the second large Chicago fire of 1874. The business was then merged with the Western Electric Company, of which Mr. Bliss was director and general agent for three years. In 1877 he became associated with Mr. Edison and handled his specialties in this country and Europe for two years. In 1879 he started the Electric Merchandising Company, at Chicago, which concern had a license to manufacture some of the Bell telephone apparatus. Afterwards he became general Western agent of the Edison Electric Light Company. His efforts resulted in the formation of the Western Edison Light Company, of which he was superintendent for three years. At present he is president of the Ozone Company, treasurer of the Rowell Potter Safety Stop Company and identified with other electrical enterprises.

—

B. F. Stewart.

Mr. B. F. Stewart was born in Virginia in 1854, and began his first experience of any consequence with electrical work in 1880. He went to Chicago with Mr. Van Depoele in 1880 and was with the Van Depoele Electric Co. from that time to September, 1884, during all Mr. Van Depoele's early electric railway experiments. Mr. Stewart then went with the Western Electric Co. for four years, and was afterwards with the Sprague Co. in the Chicago office until April of 1890, when he became connected with the Westinghouse Electric Co. and at present has charge of their Chicago office.

—

George H. Wadsworth.

The first electric light carbon salesman in this country was Mr. Geo. H. Wadsworth. Born February 28, 1851, near Columbus, O., at the age of 21, while acting as assistant chief in the Western Union telegraph office at Cleveland, O., he became greatly interested in the subject of electricity. The wires for the first duplex and quadruplex instrument ever used in that office were run by him at that time, and the first telephone in the city of Cleveland was put up by him in the winter of '78-79. He was afterwards made chief of the Western Union office, acting in that capacity until he resigned to enter the Arnoux Electric Light Co. Later on he was connected with the Boulton Carbon Co. of Cleveland, and lastly with the Thomson-Houston Co. at Chicago. An attack of pneumonia while at the Windsor Hotel in New York, in 1887, left him greatly broken in health. He died in Kansas City, July 29, 1889.

—

James F. Kelly.

Mr. James F. Kelly was graduated from Stevens Institute of Technology in 1879, taking his degree of M. E. His first business connection was with the Gold and Stock Telegraph Company as telephone inspector. Later he was with the Western Electric Company for three years and with the Electrical Supply Company for about the same time. In 1886 he became general sales agent of the Edison Machine Works. When the U. S. Wire and Cable Company was formed Mr. Kelly took the position of manager of the sales department. He is now with the New York Insulated Wire Company in Cortlandt street.

Frank Ridlon.

Mr. Frank Ridlon, one of the earlier pioneers, first became connected with the electrical business in the year 1879 with the New York office of the Brush-Swan Electric Light Company. He sold the first plant to the Havemeyer Sugar Refinery in Williamsburg, N. Y., and in 1880 went to Boston as the New England agent for the above-named company. He retained this position until the fall of 1888, when he took the agency of the Baxter motor for New England, and was appointed treasurer of the Sun Electric Company. On April 1st, 1889, he established the firm of Frank Ridlon & Co., Boston, which was changed to the firm of Frank Ridlon Co. on June 1st, 1894, with offices at No. 180 Summer street, Boston.

—

G. W. Hart.

Mr. Gerald W. Hart, after leaving the Sheffield Scientific School of Yale College, entered the employ of the Thomson-Houston Electric Company upon its organization as the American Electric Company at New Britain, Conn., in July, 1880. He remained at the factory at New Britain until the spring of 1882, going out occasionally to install isolated plants. In April, 1882, he was sent to Kansas City, Mo., to install for the Kansas City Electric Light Company the first central station using the Thomson-Houston system. From that time until December, 1886, he remained in the employ of the Thomson-Houston Company, and was located at various points in the West, selling and installing arc lighting apparatus for that company. Early in 1887 he returned to Kansas City permanently, and was made assistant general manager of the Kansas City Electric Light Company and superintendent of the Edison Electric Light and Power Company of that city. In 1891 he formed a partnership, under the name of the Hart & Hegeman Manufacturing Company, with George S. Hegeman for the manufacture of electric light supplies. In May, 1891, the business was removed to Hartford, Conn., where they are now located.

—

F. W. Harrington.

Mr. Frank W. Harrington was born about forty-two years ago of New England ancestry. In 1870 he became connected with Mr. C. Williams, Jr., in Boston, and was closely identified with some of the earlier experiments in both telephone and electric lighting work. Later he was sent abroad and did important telephone work both in England and the West Indies. In 1885 he went with the Western Electric Company of New York and Chicago and remained until 1890, when he took charge of the New York branch of the Tropical American Telephone Company. In 1892 he joined the forces of the New York Insulated Wire Company, remaining there until last December, when he resigned to take a similar position with Mr. J. W. Godfrey in the interests of Habirshaw wire.

—

John A. Seeley.

Mr. John A. Seeley says he was born in Virginia in 1855, and we think he must have made a mistake as he looks ten years younger. He entered into the electrical business in 1878 with the American Union Telegraph Company. In 1879 he became connected with the City and Suburban Telephone Company of Cincinnati, O. In 1882 he accepted a position with the Metropolitan Telephone and Telegraph Company, New York City, as their electrical engineer, and resigned from this position in 1888 and embarked in the construction business. He has been one of the most active members of the National Electric Light Association, and is now president of the Complete Electric Construction Company of New York.

—

C. O. Baker, Jr.

Mr. Cyrus O. Baker, Jr., was born in Newark, N. J., in 1857, on October 12th. This latter date will be noted as the same upon which Columbus discovered America. He came actively into the electrical business in 1879, and at present his chief connections are with C. O. Baker & Co., platinum refiners, and with the Complete Electric Construction Company, of which latter he is vice-president. He is well known as the gentleman who looks after the comforts of the excursionists at the time of the annual meetings of the National Electric Light Association. In addition to his other duties he has for some time served as valet to Mr. John A. Seeley.

A. H. Reece.

Mr. Achilles H. Reece was born in Allegheny City in 1851 of Quaker parentage. His first employment was in the shops of John M. Cooper & Co., Pittsburg, as machinist's apprentice. In 1872 he went to California, where, as he says, "I entered into competition with a score of Shoshone Indians, and as the main question seemed to be cheapness of cord wood, I concluded to let the Indians have the contract all to themselves." Mr. Reece then went to sea for three years, turning up in Cleveland in 1875 as gas engineer in the Euclid Avenue Opera House, where he first met Mr. Charles F. Brush. In 1877 he was again in California, and associated with Mr. Stephen D. Field in the exploitation of the Jablochkoff system. He again spent a few years at sea. In 1881 Mr. Reece entered the employment of the Brush Electric Company, and was sent to the City of Mexico in their interests, starting the first Brush plant in that country.

B. F. STEWART.

J. F. KELLY.

FRANK RIDLON.

GEORGE H. BLISS.

C. O. BAKER, JR.

F. W. HARRINGTON.

G. W. HART.

JOHN A. SEELEY.

Subsequently he travelled extensively through South America for the Brush people, and later joined the United States Company. Afterwards he was with the Edison Company, and represented them as district manager in San Francisco and Denver. Early this year Mr. Reece took charge of the St. Louis business of the Fort Wayne Electric Corporation.

Charles S. Knight.

Mr. C. S. Knight was born in Ohio about 48 years ago, near the city of Columbus, and gained his earlier business experience during twenty years spent in the service of the Pennsylvania Railroad Company west of Pittsburg. He left the railroad business to become superintendent of the Fort Wayne Gas Company. After remaining with that company for several years he cast his lot in with the Fort Wayne Jenney Electric Light Company, beginning in April, 1886. He has for several years had charge of the sales department, and later has had general supervision of the sales and manufacturing departments. Mr. Knight is vice-president of the reorganized Fort Wayne Company.

Spencer Borden.

Mr. Spencer Borden was born at Fall River June 10, 1849, and was educated in the public schools of Fall River, the Brooklyn Polytechnic Institute (from which he was graduated in 1868) and the Conservatoire des Arts et Metiers, Paris. From 1870 to 1872 he held the position of chemist at the American Print Works, Fall River. In 1872 he built the Fall River Bleachery. In 1880 he organized the New England department of the Edison Electric Light Company, establishing many licensee stations which have become good properties. In 1882 he returned to the management of the Fall River Bleachery, with which he is at present identified.

GEORGE W. WADSWORTH.

Henry Hine.

Mr. Henry Hine was born at Bridgeport, Conn., in 1859. He entered the employ of the United States Electric Light Company, New York, October, 1880, as assistant secretary. For nearly two years he was engaged almost exclusively on patent work, and then entered the commercial end of the business as salesman. In the spring of 1883 he went to Chicago and assisted in establishing the United States business there, travelling widely through the West as salesman. He returned to New York in the spring of 1885, took general charge of the sales department of the United States Company, remained in this position until the consolidation of the United States and Westinghouse companies in 1889, at which time he became the general district agent of the Westinghouse Company in New York, having the territory of New York, Pennsylvania, New Jersey, Maryland, Delaware and Virginia. He remained with the Westinghouse Company until February, 1891, and then left to take charge of the business of the Stanley Electric Manufacturing Company, of Pittsfield, of which he is at present general manager.

A. H. REECE.

J. W. Godfrey.

The birthplace of a man like James W. Godfrey counts for little. We all know him, and that he is about 48 years old. After a successful commercial experience he took the management of the sales department of the New York Insulated Wire Company about nine years ago, and the results of his work are in evidence. He was a prominent member of the New York Electric Club until its untimely death, and was a member of the board of managers. In December of last year Mr. Godfrey retired from the New York Insulated Wire Company and is now in charge of the sales department of the India Rubber and Gutta Percha Insulating Company, with offices at 15 Cortlandt street, New York.

H. C. Adams.

Capt. H. C. Adams was born in Schuyler County, New York, in 1845, and enlisted in the United States Army in August, 1861, being at that time less than sixteen years old. Mr. Adams served in the army until the close of the war, and was mustered out in August, 1865, after a service of four years. He then entered Lowell's Commercial College at Binghamton, N. Y., from which he was graduated, and on March 9, 1867, accepted a position with Holmes, Booth & Haydens as collector, and remained in their employ until 1887. He left their service to accept a position with the American Electric Manufacturing Company, which was at that time becoming a factor in electric lighting circles. With this company Mr. Adams became successively factory manager and purchasing agent, secretary, treasurer, and finally president. In 1888 he took charge of the New York office of the Fort Wayne Electric Company, and remained with that company until January 1, 1893, when he accepted the position of president of the Phillips Insulated Wire Company of Pawtucket, R. I., which position he now holds and is in charge of their New York office.

James W. Godfrey.

Walter F. Smith.

Mr. Walter F. Smith, general manager of the United Electric Improvement Company of Philadelphia, has enjoyed whatever advantages attach to very early schooling in the electrical line, having been a protegé of Moses G. Farmer and a member of his family. His connection with the business dates back to 1869, in the old Wallace establishment at Ansonia. He was actively interested in the electroplating business, and has a fund of reminiscences of the early days which should not be lost to history.

F. A. Scheffler.

C. A. Bragg.

J. E. Ridall.

Geo. L. Wiley.

John E. Ridall.

Mr. John E. Ridall's first connection with the electrical business dates back to the spring of 1880, when he made a contract with the Brush Electric Company, taking the exclusive license and agency for the territory comprising the western part of Pennsylvania and counties bordering the Ohio River in the States of Ohio and West Virginia. At that time the company's name was the Electrical Supply Company, which afterwards merged into the Brush Electric Company, the capitalization then being $100,000. Mr. Ridall built the first electric railway in that section, started the first electric light company, which is the Allegheny County Light Company, and for the first few years was its vice-president and business manager. It started with $150,000 capital, and now has an authorized capital of $1,000,000 with $560,000 issued and $500,000 bonded debt, and is in a flourishing condition. He has been a successful salesman, and still retains the license for Brush apparatus in his original territory.

Spencer Borden.

George L. Wiley.

Mr. Wiley's electrical experience began in June, 1869, when he entered the service of the Gold and Stock Telegraph Company of New York as clerk, at their office in the New York Bank Clearing House. He served in all the intermediate grades until his appointment in 1878 to be superintendent, and the telephone business of the company for New York, Brooklyn and Jersey City was put under his management. In 1880 the present Metropolitan Telephone Company was formed. In that company Mr. Wiley was assistant general manager until June, 1882, when he sailed for the Republic of Mexico as vice-president and general manager of the Mexican Telephone Company. After three years of successful work there, he returned to New York nine years ago and assumed his present position with the Standard Underground Cable Company. Mr. Wiley is not only a good salesman, but has gained some credit as an inventor.

Walter F. Smith.

Charles A. Bragg.

Mr. C. A. Bragg was born in St. Louis, Mo., in 1850, and was educated in the Union High School and Stamford University, preparing for Yale at the latter place. In 1883 he took up the study of electricity, and in 1886 entered the employ of the United States Electric Lighting Company, locating in Philadelphia. At that time Philadelphia had one United States plant of 400 lights; in three years this was increased to a number of plants aggregating 85,000 lights. When the Westinghouse Company absorbed the United States Company he continued with them as manager of the Philadelphia Agency, which office he still retains.

H. C. Adams.

Henry Hine.

F. A. Scheffler.

Mr. Frederick A. Scheffler was born in Galion, O., was graduated in 1875 from the Paterson Seminary. He became a draughtsman on the Long Island road in 1875, and went with the Long Island Locomotive Works in 1877 to 1879. During 1880 he was with the Harris Corliss Engine Company at Providence. From 1881 to 1884 Mr. Scheffler had charge of the engineering department of the Edison Company for isolated lighting. In 1881 and 1882 he designed the first electric locomotive, which Mr. Edison built for experimental work at Menlo Park—the narrow gauge road, using the rails for conductors. After 1884 and until 1889 he held the position of superintendent Erie City Iron Works, Erie, Pa; then engaged, until 1891, with the Westinghouse Electric and Manufacturing Company as acting general superintendent. From 1891 to 1893 was superintendent of the Brush Electric Company at Cleveland, Ohio. At present he is general sales agent for the Stirling Company, manufacturers of water-tube safety boilers.

Charles S. Knight.

Col. Geo. L. Beetle.

Col. George L. Beetle was born at Edgartown, Mass., July 7, 1832. In 1847 he entered the service of the Erie and Michigan Telegraph Company (now Western Union) as messenger boy in the Milwaukee office. Soon after he was employed by the Wisconsin Telegraph Company as operator, and opened the offices at Waukesha, Palmyra, Whitewater, Fort Atkinson, Jefferson and Beloit, Wisconsin. After several years' service with the Wisconsin Telegraph Company, Col. Beetle in 1855 was appointed manager of the Milwaukee office. In 1874 he accepted a position with the Western Electric Company, and excepting absence of three and one-half years in Europe and a brief business experience in New York, he has been in the employ of the Western Electric Company up to the present time. Col. Beetle is easily the patriarch of the present list of old-timers.

—

Col. S. G. Booker.

Col. Samuel G. Booker was born in Amelia County, Virginia, so long ago that he never tells just when. He served under "Jeb" Stewart as a cavalryman in the Confederacy, and has an honorable record as a soldier. He is as ready now to fight for the stars-and-stripes as he was 35 years ago for the State of his birth. He went to St. Louis in 1870. He was an operator on the Virginia and Tennessee Railroad, occupying the position at the same time when stationed at Christiansburg of postmaster, freight agent, etc., and was at times even a justice of the peace. He was for many years connected with the Fidelity Carbon Company in St. Louis, having inaugurated the carbon business in that city. He is now general manager of the Phœnix Carbon Company of that city, who have succeeded to the plant of the Fidelity Company.

A. F. Stanley.

—

A. F. Stanley.

Mr. A. F. Stanley is one of the early birds, having started in the electrical business with the Western Electric Company in Chicago in 1873. Shortly after that time he commenced travelling for that company through the Western States. In 1884 he came to New York, and traveled through the East until 1887, when he started in the electrical supply and manufacturing business. He is at present senior member of the firm of Stanley & Patterson, general supply dealers in Frankfort street, New York.

—

W. L. Candee.

Mr. Willard L. Candee was born in 1852, and he began his electrical career in 1876 as assistant superintendent of the New York Telephone Company. He was subsequently manager of the Western Electric Light Company in Centre street, New York, and still later was connected with the Jablochkoff Electric Light Company. In 1883 he joined hands with the Okonite Company, Limited, in the growth of whose business he has been an important factor. Mr. Candee was one of the leading members of the New York Electric Club and for five years its treasurer. He has also been a popular member of the Thirteenth Regiment N. G., S. N. Y., and some years ago was chosen captain of one of the companies composing that regiment. He is at present the guiding spirit in the sales department of the Okonite Company, Limited.

George F. Porter.

Mr. George F. Porter was born on March 12, 1855, in Pittsburgh, Pa., and was graduated from the public schools of that city in 1871. He began life as a civil and mechanical engineer and continued that profession until 1873. During 1875 he first turned his attention to electrical work, commencing in this business as a telegraph operator. Until 1877 he was connected with the Pullman Palace Car Company. In 1883 he went into the carbon business, and later held a position with the Westinghouse Electric Company in their Philadelphia office. During Mr. Huntley's term as president of the National Association he was appointed to the position of secretary, and has been reappointed successively by Messrs. Ayer, Armstrong and Francisco.

Willard L. Candee.

George L. Beetle.

—

C. C. Warren.

The blue pencil of the editor has refused to move across the manuscript of which the following is a verbatim copy. Every old-timer in the list will, we are confident, enjoy it all :

A REMINISCENCE.

Who among the old stagers that fell under the spell of electrical fascination does not remember the special edition of the New York *Herald*, issued in the winter of 1878-9, portraying the Aladdin possibilities of Edison's discoveries in the subdivision of the electric current that was to knock into a cocked hat all the gas monopolies in Christendom and become itself the colossal monopoly that was to enrich every fellow fortunate enough to secure one of the shares.

George F. Porter.

"Go to Menlo Park and witness the marvelous exhibition." I went. I couldn't buy one of those $100 shares for less than $4,500. I didn't buy. Some did, I was told, who afterward looked upon it as a South Sea bubble.

I wanted to be a millionaire, and with unseemly haste applied for a license to establish an Edison plant in the goodly city of Toledo, O., where I then resided. A reply came forthwith on a lovely blank form, that my "application would be placed on file." About a hundred others from the same city made application for the privilege, showing that I was not lonely in my desire to get rich. All those applications are still "on file." In 1879-80 I became tired of waiting, and being determined to signalize myself as a pioneer in the introduction of electricity in the city of my home, I made the discovery of the United States Electric Lighting Co. of New York, who with their Maxim incandescent system (they talked "system" even then) and the Weston arc light system. left all the other systems as pale and attenuated stars in the grand planitary systems of the universe.

I struck a deal, and acquired fame when those four, ten light Weston arc machines came up to speed and generated a current that set those forty arc lamps aglow with a radiance so dazzling as to cause all the shareholders of the modestly incorporated company (under the Ohio double liability law) to button their shares of stock securely in their pockets for future balloon prices. 'Twas a great event, brief but glittering, for soon these shareholders went down into the aforesaid pockets, sadly and reluctantly fishing out a $100 note with each $100 share of stock, for the purpose of rounding up that extraordinary financial investment and relieving themselves from the insidiousness of the Ohio statutes.

Meanwhile the astute officials of the United States Electric Lighting Co. in the exercise of their usual sagacity came to the startling conclusion that I was designed by nature to fill a great aching void in the commercial vacuum of electrical development. History records that for a paltry consideration I became their servant, and in the year 1882 opened a modest office in basement No. 185 La Salle street, Chicago, surrounding myself with a complete corps of assistants, consisting of one lonesome stenographer (just out of school) and a young gentleman named Chas. D. Shain, stranded, but inspired with the idea that he, too, was eminently endowed by nature to swash around in the electrical vacuum. In his case, nature apparently did a good job.

S. G. Booker.

The growth of this modest undertaking from 1882 up to 1890, was by no means insignificant, covering a business measured by the installation of 411 separate plants, big and little, scattered over a dozen of the Western States, among these being some of the most prominent office and Government buildings in Chicago, St. Louis, Cincinnati and all other Western cities, nearly all of which are being operated successfully and satisfactorily at the present time.

In the sale of chattels by the United States Electric Lighting Co. to the Westinghouse Co., the writer was excepted, and a few months later inaugurated the business of the Edison Co. in Chicago, known as the "Central States District."

To those familiar with ancient (electrical) history, it need not be mentioned that previously there had been no great and enduring love, no ecstatic condition existing between the aggressive representative of the U. S. Co. and the Edison Co., so that in the writer's new environ his sensations were probably much like those of the Angel Gabriel's cornet player, taking a job when business was dull of Mephisto, with whom he had not been on the best of terms, but as the c. p. said, "Business is business, and I'll blow just as hard for Meph as I did for Gabe," and he did. Strict accuracy compels me to say, however, that again, like the c. p. alluded to, neither the climate nor morals of the new environment was wholly satisfactory.

The wild scheme then took possession of me that Mr. Westinghouse ought to build street car motors and engage actively in the electric railway business, and I thought I was ordained to convert him and lead him into the true path. He listened, acknowledged the error of his way, but spurned the truth. He listened again, he hesitated. The old story—"he who hesitates is lost." He went into it, he took me in. That was in 1891—you know what happened then, and since.

I haven't represented any company actively in the electrical business since that event. My dome of thought has been bulging, however, and I hope to be ere long in the swim, with the "Warren Alternator," the advanced idea, the slow speed—variable phase—multi-potential—brushless—commutatorless Alternator. (A limited number of shares only for sale.)

In my eagerness to give you my history that you have asked for, I came near forgetting to tell you about that first meeting of the National Electric Light Association. It was held in one of the dark rooms of the Grand Pacific Hotel one evening sometime in the winter of 1883-4, at which were present a lot of us visionary chaps—about all there was at that time except touch-me-not Edison Co. There was present: Brown, of the Western Electric Co., who thought his company's interests would be enhanced; Sperry, who was sure the Sperry Electric Co. would be boomed; Bowen, who talked towers, and talked them high. Terry and Reed wanted to talk to a convention upon the safety of Underwriters' wire, Hammett upon the steam engine, Bullock upon the existence of the Brush Electric Company, and your humble servant wanted a convention to talk to on the advantages of the Weston shunt wound arc dynamo for series arc lighting.

The Convention took root from that small planting, and all the world knows what it has done, how the various hotels in the Convention's perambulations have profited; how the railway companies have been struck for special rates, with Pullman buffet car attachments; and how those gilded, mirrored, mahogany and cut glass equipped parlors could betray secrets would they but speak; and how, incidentally, electrical information and science have been disseminated. I have attended some of the Conventions—why need one attend all? Human capacity has its limitation. I was full. Others are capable of absorbing more intellectuality, general information and other things than I. To all such I would say most emphatically, attend the National Electric Light Conventions, all of them.

When I was born in Wyoming County, State of New York, along in the thirties, within hearing of the roar and thunder of Niagara (when the wind blew right), no one dreamed that within the period of a single generation the festive mule of the tow path near our back door would wink his starboard eye and make his politest bow to the shining trolley that was doing his work by the forces of the mighty cataract, forty miles away, through the medium of subtle electricity. Grand thought—the Convention should grapple with it. Yours truly, C. C. WARREN.

Chicago, Jan. 22, 1895.

C. C. WARREN.

Personal.

H. T. Edgar, secretary and general manager, and Oscar Turner, purchasing agent, of the Georgia Electric Light Company, at Atlanta, Ga., will be at the Cleveland Convention of the National Electric Light Association as representatives of the Cotton States and International Exposition, to be held at Atlanta, Ga., September 18th to December 31st. Mr. Edgar and Mr. Turner propose to make a trip through the North, taking in the principal cities, where they will confer with the supply houses and electric companies relative to exhibits at the Exposition.

1885—N. E. L. A.—1895.

How the Association Was Organized.

The First Meeting.

The formation of the National Electric Light Association was due to the efforts of Mr. George S. Bowen, then president of the Elgin Electric Light Company, who, in November, 1884, wrote a letter to the *Electrical Review*, outlining the proposed plan which first attracted general attention to the subject.

MR. GEO. S. BOWEN.

The parent companies at first, especially the Brush and Edison, opposed the idea, but their opposition was not sufficient to dampen the ardor of those with broader minds.

The first meeting to discuss the formation of the Association was called by Mr. Bowen, and held at the Grand Pacific Hotel in December, 1884. The following were among those present: Geo. S. Bowen, president Elgin Electric Light Company; C. C. Warren, Western manager United States Electric Lighting Co.; Elmer Sperry, electrician Sperry Electric Motor and Car Brake Co.; W. A. Hammett, Western manager New York Safety Engine Co.; J. H. Reed, with Electrical Supply Co., Chicago; F. S. Terry, manager Electrical Supply Co., Chicago; C. A. Brown, Western Electric Co.

At this meeting Mr. Geo. S. Bowen was appointed chairman and John H. Reid secretary. There was but one other meeting of those in charge of the preliminary work, and this was held in January, 1885, when it was definitely decided to hold a meeting in Chicago at the Grand Pacific Hotel, and a date was named and a committee was appointed to prepare and issue an invitation, this committee being composed of Elmer A. Sperry, Geo. S. Bowen and F. S. Terry.

The first meeting was held at the Grand Pacific in February, 1885, and Mr. Geo. S. Bowen was chosen temporary chairman, and afterwards Mr. Frank Morrison, of Baltimore, was elected first president.

Following is a copy of the minutes of the first meeting:

CHICAGO, Ill., Feb. 6.

At a meeting of electric light representatives, held at the Grand Pacific Hotel, Chicago, on the evening of February 3d, presided over by C. A. Brown, of Western Electric Co., resolutions were passed that the chairman appoint the following committees:

Committee of Arrangements.

Geo. S. Bowen	Van Depoele Elect Mfg. Co.
C. C. Warren	United States Elect. Lighting Co.
E. B. Palmer	Sperry E. L. Car Brake and Motor Co.
Geo. L. Crossman	Thomson-Houston Co.
C. A. Brown	Western Electric Co.
Wm. A. Hammett	The New York Safety Steam Power Co.

Committee of Invitation.

E. A. Sperry	Sperry E. L., C. B. and Motor Co.
F. S. Terry	The Electrical Supply Co.
Geo. S. Bowen	Van Depoele E. Mfg. Co.

Finance Committee.

M. A. Knapp	Railway Telegraph Supply Co.
S. S. Badger	Badger Electric Co.
M. A. Buckley	Excelsior Electric Lt. Co.

Treasurer.

W. A. Kreidler	Western Agt. "Electrical World."

Secretary.

J. H. Reid	The Electrical Supply Co.

London Notes.

(From our London Correspondent.)

EUROPEAN ELECTRICAL EXHIBITIONS.

There are to be at least two good exhibitions in Europe during this year. One of these will be at Vienna in May, and will be devoted to all classes of machinery and apparatus employed in connection with agriculture and its branch industries.

Electrical apparatus is to have a special prominence, and it is to be hoped that as a result of this exhibition there will be developments in this department of the electrical business. The exhibition will only remain open for about a week, so it can hardly be expected that exhibits will be sent from a great distance, and without articles from England and America it will be a poor show.

ELECTRIC TRACTION.

The tardiness with which we do things over here becomes every day more wearying, and these remarks specially apply to our backwardness in adopting electric traction. There are already obstacles enough placed in the path of the electrical engineer if he dares to think of even suggesting electric tramways or railways, but the London County Council have now made it all the harder. The London United Tramway Co. wanted to abolish horse traffic and were intending to install the overhead electric system over a portion of their line. Of course they had to apply to the County Council for powers, and on the 29th inst. they refused their permission. Some of the labor members thought the blue sky would be hidden, the streets disfigured, people use the lines as clotheslines, and the kites of playful lads would attach themselves thereto. A host of foolish statements were made and the minds of the councillors convinced that an overhead electric tramway must be a most outrageous thing. Thus, what would have been a most interesting, important and progressive work of British electrical engineering is for the present shelved. The London County Council is a body professing to care for the laboring classes, and by this unwise decision they have prevented an extensive piece of work being carried out.

The Dublin United Tramways Co. are of opinion that horses are out of date, and have accordingly resolved to abolish them over a portion of their system and adopt electricity as the motive power.

The Man Who Started First.

MR. MARCUS NATHAN.

[On Friday, Jan. 18, Mr. Marcus Nathan, whose portrait is printed above, rushed into the office of ELECTRICITY in breathless haste, travelling bag in hand, and wanted to know if he had time to get a shave before the departure of the Cleveland Convention Special. Mr. Nathan, always up to date, is here.]

The Transactions in Local Stocks and Bonds.

Companies in Which the G. E. Co. and Its Financing Companies Have Holdings.

Following is a complete list of the holdings of the G. E. Company and the three financing companies in various local properties. The statement was made up a few months ago from the company's books, and is exact excepting the few sales of stocks and bonds since the date of compilation :

GENERAL ELECTRIC COMPANY.

NAME.	ISSUED.		HOLDINGS.	
	Bonds.	Stocks.	Bonds.	Stocks.
Andover Electric Light Company	$28,000	$30,000	.....	$2,000

THE PHOSPHORESCENT LIGHT.

In response to an invitation from Mr. E. J. Wessels, vice-president and secretary of the Moore Electrical Company, a party of about a dozen notable electrical experts assembled last Tuesday evening at the laboratory of the company at Harrison, N. J., to witness a confidential exhibition of some results obtained by Mr. D. McFarlan Moore in the line of phosphorescent lighting. This opportunity was one which few who were so fortunate as to receive an invitation could resist, and all were well repaid for the trouble by the most interesting and brilliant display of the "new light" which they witnessed. As to the technical details of the apparatus employed the lips of the visitors are sealed for the present, but we believe we are violating no confidences in the following outline:

The invited guests, after having assembled at the laboratory, were first shown through the extensive establishment and then ushered into a small room where chairs had been provided and where Mr. Moore explained the general principles of his method and then illustrated its practical working.

He said in substance that heretofore the results which he was about to show had only been accomplished by means of extremely high potentials and frequencies. These involved either very expensive, specially constructed alternators, or large induction coils, condensers, etc., which would cost hundreds or thousands of dollars to construct. He proposed to show that these same or similar results could be accomplished by apparatus that would cost but a few cents, and which was ideal in its simplicity.

The energy used in most of the experiments which followed was the ordinary 110 volt direct current, modified for his purpose by the introduction in series with the lamps of the little "vibrator" which constitutes the gist of his invention. In the earlier stages of his work he had supposed that one of these vibrators would have to be attached to each lamp, but he had found by experience that this was not necessary, and that the insertion of a single instrument, the whole of which could be carried in the vest pocket, in the supply mains, was sufficient for all the lamps supplied therefrom.

The lamps shown, of which there were a variety of forms, were really condensers. They were ordinary incandescent lamp bulbs into which two plates separated from each other had been inserted—one connected with the positive and the other with the negative side of the circuit. The bulb was then exhausted, and when the terminals were connected into the circuit, acting inductively upon each other, produced the most beautiful phosphorescent effects. The plate connected with the positive side of the circuit was always far less luminous than the other, but in several cases there appeared a beautiful flame-like excrescence—in one instance fully half an inch long and covering an area of a quarter of a square inch. This flame seemed to be nearly white, but the chief light of the lamp came from the other plate and resembled closely the familiar Geissler tube effects only more brilliant.

When one of these lamps was burning everyone in the room could be distinctly recognized, the shadows on the walls were visible, and nonpareil type easily legible a few feet away from the lamp.

The inductive surfaces were not always true planes, but more often were spirals of iron wire, sometimes with their axes concentric, sometimes eccentric. In other lamps a plane surface faced such a spiral, but in all the effect was essentially the same.

As to the energy consumed Mr. Moore was unable to give any very definite information, but in proof that it was small he produced the same results, though with less brilliancy, when his source of energy was, 1st, a Grenet (bi-chromate of potash) cell; 2d, a small cell of dry battery, and finally a little chloride of silver cell not more than an inch in diameter and four inches long.

Mr. Moore closed the evening's entertainment by showing the adaptation of his method of electrical control described in his paper before the Institute on September 20, 1893, to the turning down of incandescent lamps. By this exceedingly simple and inexpensive means he showed that lamps could be reduced to low candle power quite as efficiently on direct currents as on alternating currents.

After this most enjoyable demonstration, and congratulations to Mr. Moore and Mr. Wessels, the party, much pleased and instructed, returned at a late hour to New York.

LEGAL NOTES.

The Interior Telephone Company, on February 12th, commenced suit in the United States Circuit Court for the Southern District of New York against the Tucker Electrical Manufacturing Company, of 14 Whitehall street, and against James R. Strong and Thomas McConbray, as individual co-defendants, for the infringement of Colvin patents Nos. 513,305 and 524,524.

The Campbell Electric Supply Company, 104 High street, Boston, has made an assignment, to close up the business, to R. A. Stewart, treasurer of the company.

General News.

What is Going on in the Electrical World.

Bridgeton, N. J.—The electric light plant at Woodbine was destroyed by fire on the 9th.

Biloxi, Miss.—Application has been made to the council for a franchise for electric street cars by E. G. Burklin of Vandalia, Mo.

Topeka, Kan.—An act is before the Senate making appropriations for the erection of a boiler house, electric light plant, etc., at the Girls' Industrial School, at Beloit.

Fall River, Mass.—At the last meeting of the poor commissioners the advisability of maintaining an electric light plant for the hospital was discussed, but no action was taken.

Hastings, Neb.—A franchise has been granted to the Hastings Electric Light and Power Company giving them an exclusive right to furnish the city with electric light for ten years.

Cohoes, N. Y.—President Weldon of the Cohoes City Railway Company states that bids for the construction of the road will be advertised for shortly, and that work will begin early in the spring.

Boonsboro, Md.—The Boonsboro and South Mountain Electric Railroad Company has been granted a charter and its capital stock has been placed at $30,000. The road will be completed as soon as practicable.

Fairmont, W. Va.—A movement is on foot here to build an electric road from Fairmont to Riversville by way of West Fairmont, Monongah and Barnsville. The road is to cost about $100,000 and will be 15 miles in length.

Cleveland, O.—Mayor Blee is considering the advisability of the city establishing an electric lighting plant of its own to furnish light for the city hall, the public library, the central police station and the central market.

Boston, Mass.—The annual report of the Edison Electric Illuminating Company of Boston for the year ending December 31, 1894, gives: Gross earnings, $628,206, increase, $34,318; net income, $317,164, increase, $54,913.

Kenosha, Wis.—A communication has been received here from Manitowoc asking this city to co-operate in the matter of securing a law from the present Legislature giving small cities the right to own and run their own electric light plants.

Mississippi City, Miss.—Messrs. Bennett & Cahel, concessionaires, are making efforts to get up a stock company among citizens of the Gulf coast for their proposed electric road between Pass Christian and Biloxi, a distance of twenty-two miles.

St. Louis, Mo.—The *Republic* has published a table showing the market standing of the street railways of this city, which it is understood are to be consolidated under one corporation. The total capital stock is $13,962,000; bonded debt, $16,050,000; miles of track, about 290.

Columbus, Ohio.—Managers Whiting, Hay and Apthorp of the penitentiary board, in connection with Adjutant General Howe, have been appointed a special committee to make preparations for the construction of the electric light plant at the penitentiary for which an appropriation of $22,000 has been made.

Bridgeport, Conn.—Col. N. H. Heft, president of the Bridgeport Traction Company, is to have complete supervision of the installation of electricity on the Nantasket Beach division of the New York, New Haven and Hartford Road, if the experiment proves successful. He is at the head of the company's electrical department.

Albany, N. Y.—Among the bills introduced in the Senate last week was one making the wages of gripmen, motormen, drivers and conductors $2 a day; in the House, fixing day telegraph rates at fifteen cents for ten words and one-half cent for each word extra; and the night rate at fifteen cents for twenty words and one-half cent for each word extra.

Carrollton, Ill.—Hiram M. Howard, representing the National Electric Company, has been here talking electric lights. Mr. Howard is not looking for a twenty-year franchise, but wants to put in an electric lighting plant to be owned and operated by the city. Such a plant, he says, would cost $10,000, and could be run economically in connection with the waterworks plant.

Hartford, Conn.—The Hartford Street Railway Company has created two new offices, those of vice-president and general manager. The directors have elected Samuel G. Dunham to fill the office of vice-president and Electrician Norman McDonald Crawford has been elected general manager. President E. C. Goodrich will continue to have general charge of the management of the road.

Brooklyn, N. Y.—The Edison Electric Illuminating Company's annual report for the year ending December 31, 1894, shows gross earnings, $421,073.83; operating expenses, $189,316.88; net earnings, $231,746 95. The income from all other sources was $36 529.78, which, added to the net earnings, is $268,276, from which must be deducted $44,870.71 for general expenses, taxes, etc., leaving the net income for 1894, $223,406.02.

Lynchburg, Va.—L. P. Rodes, city engineer, advertises for proposals for the complete erection and equipment of an electric lighting station for this city. The proposals must be submitted not later than Feb. 26th and must be accompanied by a certified check for $500 made payable to the treasurer of Lynchburg, Va. Any information desired can be had on application to David E. Evans & Co., No. 7 Harrison street, Baltimore, Md.

Philadelphia.—The *Times* says: "The electric surface railways could scarcely have been subjected to a severer test than was furnished by the recent storm, which was hardly excelled in severity by the famous blizzard of March, 1888. In all fairness it must be admitted that they stood this severe test extremely well. completely demonstrating the superiority of electricity as a motive power in a driving winter storm to either horses or cables."

Gouverneur, N. Y.—Electric lights for this town are to be supplied from a new plant erected by the Oswegatchie Light and Power Company at a point in the Oswegatchie River about one mile above Hailesboro. Mr. A. L. McCrea is the general manager of the company, and under his direction and that of A. J. McDonald the water power attainable has been utilized to the fullest extent and is expected to drive three dynamos, one of which is already in place.

Syracuse, N. Y.—The minutes of the stenographer taken in the reference before William Nottingham in the case of Paul T. Brady against the city and the Electric Light and Power Company have just been completed and delivered to the attorneys in the case. As soon as the attorneys can look the evidence over they will submit points to the referee, who will then make up his report, which will be handed to Justice Vann. The decision will then be made as to whether the temporary injunction secured by Mr. Brady will be vacated or made permanent.

Paterson, N. J.—The absorption of the six electric railway companies of the Morrisse system formed under the traction law of 1893 was completed on the 11th inst., and the united companies will hereafter be known as the New Jersey Electric Railway Company. Its lines will extend from Singac to the Hudson River, passing through Passaic, Bergen and Hudson counties. The company has executed a mortgage to the Mercantile Company of New York as trustee for the bondholders for $3,500,000, and the mortgage has been recorded.

The Handling of Coal and Ashes at the 3d District Station of the Edison Electric Illuminating Co., Brooklyn, N. Y.

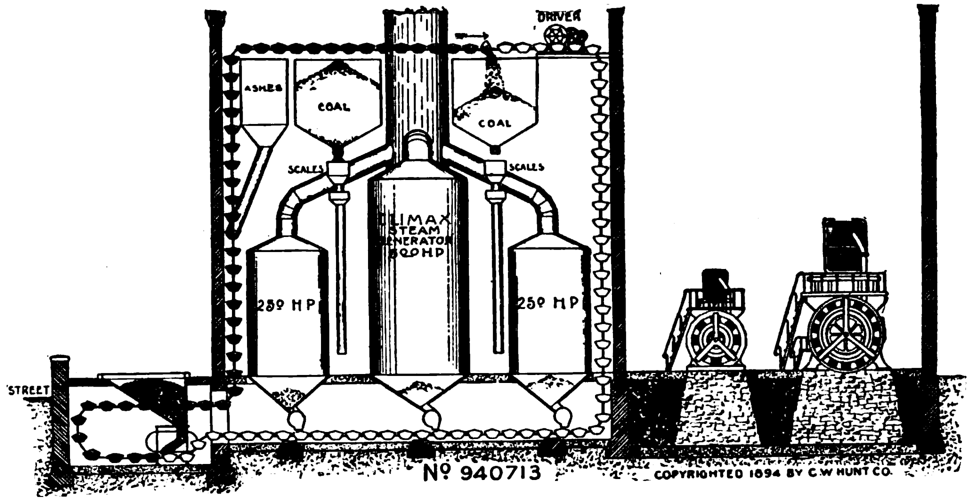
The C. W. Hunt Company, 45 Broadway, New York City, has been prominently identified with the development of coal handling machinery and installed the apparatus for that purpose in use at the Third District Station of the Brooklyn Electric Illuminating Company, at Pearl and Gwinnett streets, that city.

This station (Third District) is situated at some distance from the coal wharves, and the coal is delivered by wagons. It was necessary to take the coal from the wagons, carry it to the furnaces, and also to remove and dispose of the ashes.

The coal is now carried from the hopper underneath the sidewalk to the coal tanks above the boilers by a conveyor, which, upon its return, passes underneath the ash-pit of the furnaces and carries the ashes to a bin, from which they can be drawn at will for removal.

The conveyor consists of a series of gravity buckets pivoted in a double chain, and the whole system is carried on self-lubricating wheels. The buckets are so pivoted in the double chain that the force of gravity keeps them always in an upright position whether full or empty and no matter how tortuous the track over which they are drawn.

The material is carried to its destination by a single conveyor in a horizontal, vertical or angular direction, all of which were utilized in this station. The change in the direction of the conveyor is made by running around curves instead of over sprocket wheels, and the whole machine is noiseless in its operation.



C. W. Hunt Coal Carrying Apparatus.

The power for driving the conveyor is located at the top line, and is furnished by a ten horse-power electric motor. The operating switches are placed below on the boiler room floor for convenience in starting and stopping the machinery. At this station, when receiving coal at its full capacity, the power required to operate the conveyor is 4½ horse-power measured at the switch.

The coal is drawn from the storage bins above the boilers into weighing hoppers, from which it is spouted to the floor of the boiler room at such a distance as to be easily shovelled directly into the furnaces.

The Power Plant of the Baltimore and Ohio Belt Line Tunnel.

The Belt Line road is about seven miles long. It begins near Bayview, to the east of the city, and runs several miles through deep cuts along the northern edge of the city until it swerves around to the Jones Falls embankment, west of Oak street: it crosses the valley of this stream, the tracks of the Pennsylvania Railroad and the Baltimore and Lehigh Railroad on a large bridge, and a short distance beyond this enters the tunnel which follows Howard street through the city to the present Camden Station.

The tunnel is 7,430 feet, a little less than a mile and a half long, and it cost the Baltimore and Ohio Railroad Company between $7,000,000 and $8,000,000.

The motive power for the new electric plant is furnished from one station located near the end of the tunnel. In addition to the traction plant an electric lighting plant is found here which will supply about 2,000 incandescent lamps which are placed throughout the tunnel. As there will be no smoke in the tunnel, it is intended to paint its interior white, and when illuminated by the electric lights it will not be necessary to light the lamps in the cars of passing trains, as the passengers will find it almost as brilliant inside the tunnel as outside in the daylight. The generators will be driven by Armington & Sims engines, and the steam will be furnished from Improved "Root" Water Tube boilers. The boiler room of this plant is most interesting and includes the most modern appliances.

Twelve "Root" boilers are found arranged in six batteries, three batteries on each side of the room. Each of the two flues, which run along the opposite walls back of the boilers, carries the heated gases to economizers which rob the gases of their heat, and by this means raise the temperature of the feed water.

The gases then pass into a fan of the Sturtevant pressure pattern, which expels them through a short stack into the air. This fan establishes an induced draft, causing the air to pass rapidly through the grate bars and coal, thus promoting combustion more or less rapid, according to the speed of the fan, which is regulated by the demand for steam on the plant.

As the General Electric Company are relying entirely upon the success of this plant for their sale of it to the Baltimore and Ohio Railroad Company, they did not place their order with the boiler manufacturers until after they had thoroughly tested them in two of their plants in Lynn, Mass., which are equipped with this make of boilers.

A Good Testimonial.

THE SMITH PREMIER TYPEWRITER CO.,
Syracuse, N. Y., Mar. 3, 1894.

Onondaga Dynamo Co., Syracuse, New York.

Gentlemen: The 600 incandescent light dynamo of your manufacture that you installed about eight months ago for service in both of our factories has given the best of satisfaction.

We find the dynamo economical in point of attention, as it adjusts from a light to a heavy load automatically, which reduces the liability of breakage of incandescent lamps to the lowest possible minimum. Our engineer states that words cannot express the full satisfaction it gives. It gathers its load on starting with great promptness, and we find the commutator in as perfect condition as when the machine first started, with no appreciable wear. Yours truly,

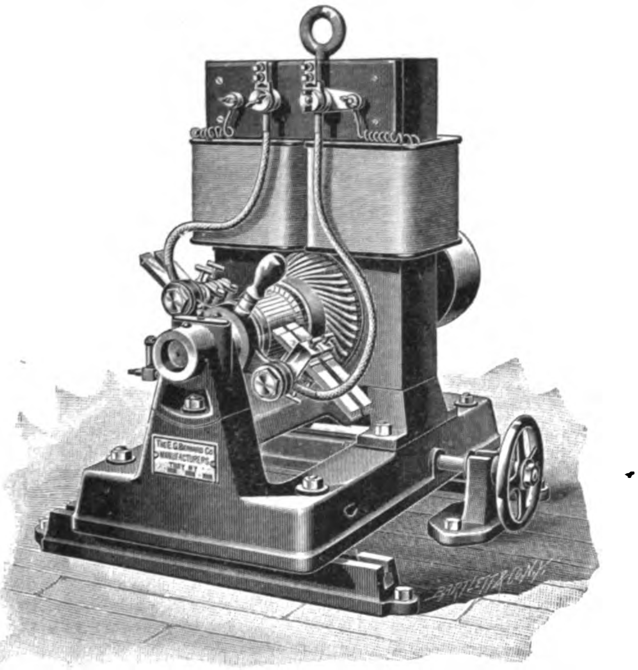
L. C. SMITH, President.

The Adams Dynamo and Motor.

The accompanying cut represents the improved Adams ynamo and Motor which the E. G. Bernard Company of Troy, N. Y., have been making for some time past. While they have not aimed at bringing out any new style or type of machine, they have greatly improved on this standard type in a number of details. One of their principal features, however, is making the magnetic field out of wrought iron forged in one piece, thus doing away with any joints in the magnetic field and decreasing the number of parts, which, from an engineering point of view, is of considerable importance, besides making an extremely simple, compact machine of high efficiency. They are the only makers in America of this type, although a number of prominent manufacturers in Europe adopted it some years ago. It has the least number of parts of any machine at present on the market.

The insulation is of mica throughout. The mechanical details are of the latest, such as self-oiling bearings, self-centering phosphor bronze journal boxes, automatic brush-holders and positive belt adjusting rails. The commutator is made of tempered copper, insulated with best quality of India mica. The dynamos are compound wound and absolutely automatic under all conditions of load.

All parts of the machines are interchangeable, and any parts proving defective in one year will be replaced free of charge.



THE ADAMS MOTOR AND DYNAMO.

The Bernard Company are just issuing an attractive price list and testimonial sheet. The latter, by the way, is a novelty in testimonials and reads as follows:

We, the undersigned, hereby certify that we have the system of Electric Lighting and Power as installed by E. G. Bernard in our factories and buildings for the period of time set opposite our names, and time thus far has proved all of his assertions and guarantees to be true, the Dynamos, etc., having given us perfect satisfaction; and we recommend this system to those desiring similar apparatus. Dated Feb. 15th. Then follows the signatures of over 100 of their customers.

The Metropolitan Electric Company.

The above company have received a letter from one of their customers that reads as follows:

"Metropolitan Electric Company, Chicago.

"Gentlemen: The bill of goods you shipped me January 9th just received, and to my great astonishment I find same to be the very first bill of electrical goods received in eight years just as ordered. You did not make a single mistake, and the goods came up in good shape, only one 32-power candle lamp broken in the entire lot. This is an extraordinary circumstance, and contrary to my previous experience with any electrical concern."

The above shipment contained parts of nearly everything contained in their catalogue. When it is considered that it travelled over 2,000 miles to reach the customer, the company may well be proud of the undertaking, and we think the general trade ought to know of it, as the feat is said to be unparalleled in the history of electrical supply business.

COMMERCIAL PARAGRPHS.

The Colburn Electric Manufacturing Company, Fitchburg, Mass., is building a brick machine-shop, and will add a boiler and engine house 42 x 40 ft.

The National Conduit Manufacturing Company have appointed Mr. H. F. Tate general Western manager, with headquarters at room 542 Rookery Building, Chicago.

Capt. Willard L. Candee and George T. Manson will be on hand at the Convention representing the Okonite Company, Ltd.

The Improved "Fishkill-Corliss" engine, built by the Fishkill Landing Machine Company, of Fishkill-on-the-Hudson, N. Y., is especially well adapted to situations where close regulation and noiseless operation is desirable, and on this account finds a ready adoption for electric light and power plants.

Those interested in the economical handling of coal and ashes in electric lighting and power stations should make application to the C. W. Hunt Company, 45 Broadway, New York City, for a copy of their finely illustrated catalogue, "Coal Handling in Power Stations."

The Abendroth & Root Manufacturing Company, 28 Cliff street, New York City, are the sole makers of the Root Improved Water-Tube Boiler, so generally employed nowadays in electric lighting and street railway power stations. It has branch offices in the Perin Building, Cincinnati, O.; Monadnock Building, Chicago, Ill.; Security Building, St. Louis, Mo., and at 8 Oliver street, Boston, Mass. The company will be represented at the Convention by Mr. P. M. McLaren.

ELECTRICAL PATENT RECORD.

LETTERS PATENT ISSUED FEBRUARY 12, 1895.

ELECTRIC RAILROADS AND APPLIANCES.

533,861. Electric Locomotive. Eben M. Boynton, West Newbury, Mass. Filed April 9, 1894.

533,869. Conduit System for Electric Railways. Frederick S. Davenport, Jerseyville, Ill. Filed Oct. 26, 1894.

533,905. Distribution System for Electric Railways. Walter H. Knight, Schenectady, N. Y., assignor to the Thomson-Houston Electric Company, Boston, Mass. Filed Nov. 30, 1894.

534,078. Regulating Device for Car-Motors or Other Electrical Apparatus. Horace F. Parshall, Schenectady, assignor to the Edison General Electric Company, New York, N. Y. Filed Dec. 11, 1891.

534,238. Supply System for Electric Railways. Malone Wheless, Washington, D. C., assignor to the Electro-Magnetic Traction Company, same place. Filed Dec. 3, 1894.

ELECTRIC LIGHTS AND APPLIANCES.

533,918. Fuse-block and Socket. Frederick W. Mount, St. John, Canada. Filed July 16, 1894.

533,932. Carbon for Arc Lamps. Elihu Thomson, Swampscott, assignor to the Thomson-Houston Electric Company, Boston, Mass. Filed Nov. 26, 1894.

534,086. Electric-Arc Lamp. Thomas Spencer, Philadelphia, Pa. Filed June 6, 1894.

534,206. Filament for Incandescent Lamps. Thomas A. Edison, Menlo Park, N. J. Filed Jan. 4, 1884.

534,207. Manufacture of Carbon Filaments. Thomas A. Edison, Llewellyn Park, N. J. Filed Dec. 27, 1886.

534,209. Incandescent Arc Lamp. Thomas A. Edison, Llewellyn Park, N. J. Filed Sept. 17, 1890.

DYNAMOS, MOTORS, ETC.

533,873. Alternating-Current Dynamo-Electric Machine. Axel Ekstrom, Lynn, assignor to the General Electric Company, Boston, Mass. Filed July 26, 1891.

533,885. Apparatus for Winding Armature-Coils. Henry Geisenhoner, Schenectady, N. Y., assignor to the Thomson-Houston Electric Company, same place. Filed Aug. 22, 1894.

533,920. Series Parallel Controller. Edward D. Priest, Schenectady, N. Y., assignor to the Thomson-Houston Electric Company, Boston, Mass. Filed Nov. 24, 1894.

533,930. Armature-Winding. David P. Thomson, Schenectady, N. Y., assignor to the General Electric Company, Boston, Mass. Filed Aug. 4, 1894.

533,931. Dynamo-Electric Machine. Elihu Thomson, Swampscott, Mass., assignor to the Thomson-Houston Electric Company, of Connecticut. Filed Dec. 29, 1890.

534,038. Dynamo-Electric Machine. Rodolphus Fuller, Detroit, Mich. Filed Oct. 20, 1894.

534,060. Electric Controller. George F. Card, Covington, Ky., assignor to the Card Electric Company, Mansfield, Ohio. Filed May 17, 1894.

534,079. Armature for Dynamo-Electric Machines. Horace F. Parshall, Schenectady, assignor to the Edison General Electric Company, New York, N. Y. Filed Feb. 20, 1892.

534,092. Means for Mounting Dynamos on Railway Cars. William Biddle, Brooklyn, assignor to the American Railway Electric Light Company, New York, N. Y. Filed May 23, 1894.

534,151. Alternating-Current Motor. Robert H. Hassler, Pittsburg, Pa., assignor to the Westinghouse Electric and Manufacturing Company, same place. Filed Nov. 30, 1894.

534,208. Induction-Converter. Thomas A. Edison, Llewellen Park, N. J. Filed May 21, 1888.

TELEPHONE AND TELEGRAPH APPARATUS.

533,893. Electrical Exchange System. George W. Hey and Arthur E. Parsons, Syracuse, N. Y. Filed March 30, 1893.

533,967. Combined Telephonic and Telegraphic System. Christopher A. Shea, Boston, assignor of one-third to Freeborn F. Raymond, 2d, Newton, Mass. Filed July 30, 1892.

534,025. Automatic Telegraphing Machine. Charles E. Yetman, Oak Park, Ill., assignor to the World Flash Company, of Chicago. Filed Dec. 2, 1893.

534,083. Telephone Metallic Circuit. Christopher A. Shea, Boston, assignor of one-third to Freeborn F. Raymond, 2d, Newton, Mass. Filed July 30, 1892.

534,084. Combined Telephone and Telegraph System. Christopher A. Shea, Boston, assignor of one-third to Freeborn F. Raymond, 2d, Newton, Mass. Filed July 30, 1892.

534,085. Telephone Metallic Circuit. Christopher A. Shea, Boston, assignor of one-third to Freeborn F. Raymond, 2d, Newton, Mass. Filed July 30, 1892.

BATTERIES.

533,936. Electric Battery. James M. Wells, Peoria, Ill. Filed July 31, 1893.

534,036. Galvanic Battery. Warren P. Freeman, Brooklyn, N. Y., assignor to the Newton Rubber Works, Newton, Mass. Filed June 11, 1894.

MISCELLANEOUS.

533,902. Electrically-Operated Recording Instrument for Compasses. Charles L. Jaeger, Maywood, N. J. Filed Jan. 25, 1894.

533,910. Tip for Electric Conductors. Amandus Metzger, Schenectady, N. Y., assignor to the Thomson-Houston Electric Company, Boston, Mass. Filed Nov. 26, 1894.

533,919. Synchronizer for Clocks. Henry S. Prentiss, Elizabeth, N. J., assignor to the Prentiss Clock Improvement Company, New York, N. Y., and Jersey City, N. J. Filed June 30, 1892. Renewed June 22, 1894.

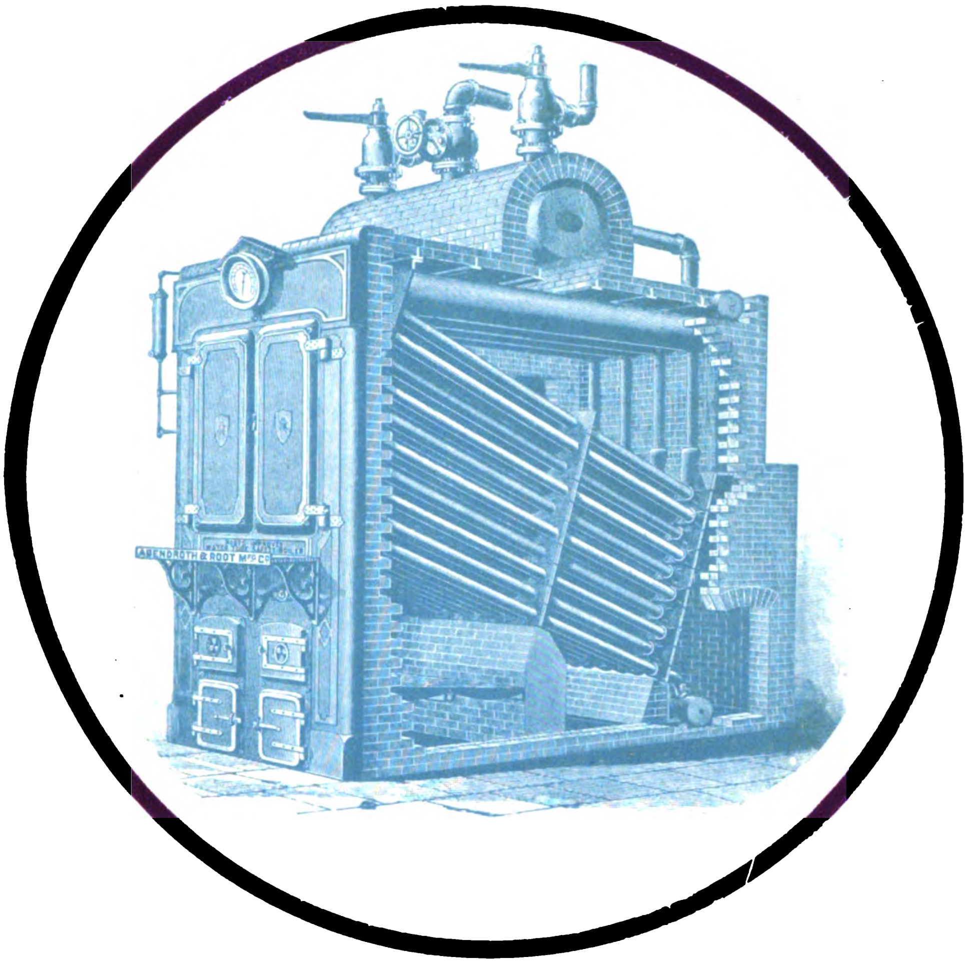
533,926. Electric Automatic Block-System Signal. Joseph P. Stewart, Haverstraw, N. Y. Filed Mar. 8, 1894.

533,979. Electrical Time-Alarm. Walther Wilke, Wermelskirchen, Germany. Filed Aug. 7, 1894.

534,028. Electric Railroad-Switch. Rollin A. Baldwin, South Norwalk, Conn., assignor to the Fitch Excelsior Switch Company, of New Jersey. Filed June 27, 1893.

534,082. Measuring Apparatus. Amos Y. Reeder, Philadelphia, Pa. Filed Mar. 14, 1894.

THE IMPROVED "ROOT" WATER TUBE BOILER



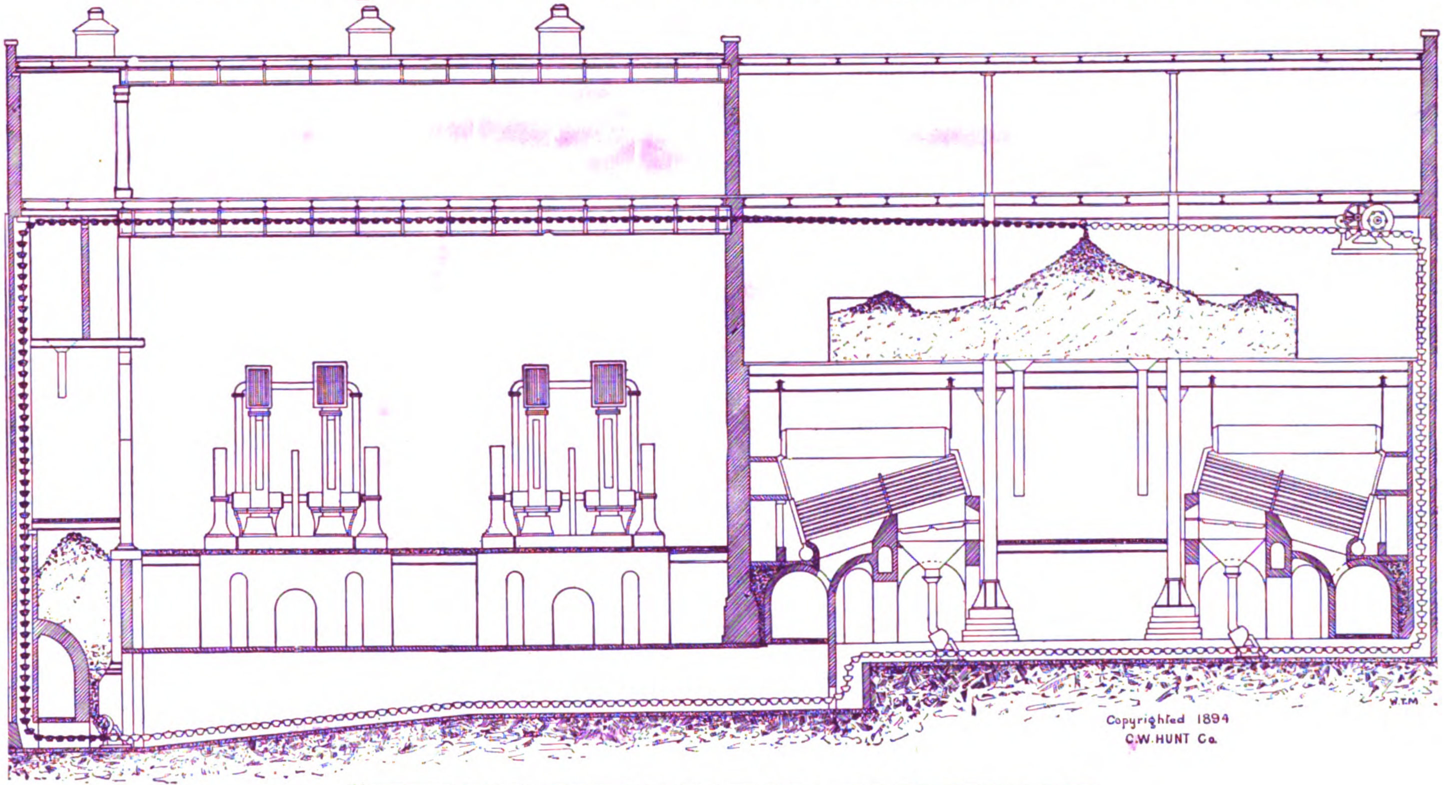
ABENDROTH & ROOT M'F'G CO.

FOR
ELECTRIC LIGHT
AND
POWER STATIONS.

BEST ADAPTED TO HIGH PRESSURES.
A Rapid and Economical Steam Generator.
FURNISHES DRY STEAM.

ABENDROTH & ROOT
M'F'G CO.,
28 CLIFF STREET,
NEW YORK.

"HUNT" System of Coal Handling in Power Houses.



"HUNT" NOISELESS CONVEYOR.

A complete system of storing and conveying coal. Coal is carried to the boilers, and the ashes are carried away by the same machine, at less cost per ton than by any other machinery.

This illustration shows the "HUNT" conveyer as constructed for handling coal and ash at the Pearl Street Station of the Edison Illuminating Company, Brooklyn.

We invite correspondence, and will be pleased to furnish complete plans and estimates for handling of coal and ash. You cannot afford to install any method of coal handling until you have investigated the "HUNT" system.

Send for a Catalogue.

ELECTRICITY.

VOL. VIII. NEW YORK, FEBRUARY 27, 1895. No. 7

ELECTRICITY.

Published every Wednesday by the

ELECTRICITY NEWSPAPER CO.

B. E. GREENE, PRES'T. L. J. MONTGOMERY, SEC'Y.

PUBLICATION OFFICE:

6 Park Place - New York

EDITORS:
NELSON W. PERRY.
BURTON E. GREENE.
R. H. WILLOUGHBY.

SUBSCRIPTION RATES:

UNITED STATES,	$2.50
IN CLUBS OF FIVE OR MORE,	$2.00
FOREIGN COUNTRIES,	$4.50
SINGLE COPIES,	10 CENTS

ADVERTISING RATES:

As ELECTRICITY reaches all classes interested in electrical work, its value as an advertising medium can be readily appreciated. Rates will be sent on application.

Changes for advertisements should reach the office not later than the Saturday preceding the date of publication.

ENTERED AT THE N. Y. POST OFFICE AS MAIL MATTER OF THE SECOND-CLASS.

EDITORIAL NOTES.

The Monocyclic System. This paper, which together with its discussion will be given in full in the columns of ELECTRICITY, meant far more to those who assembled at the Cleveland Convention than appeared on the surface. To the Central Station man and the average electrician it meant a disclosure of a new system of distribution by means of periodic currents whereby greater elasticity was expected than had even been claimed for systems already in use or described. The claims which had already been promulgated for this system had been of such a nature as to arouse curiosity to the highest point as to how the results could be accomplished and as to the actual economies resulting, and the classes above referred to attended with the expectation of having these points cleared away and of learning from the discussion how the system as a whole was regarded by those more competent than themselves to judge from *a priori* reasoning. It is unfortunate for any invention that it be heralded with too high a blaring of trumpets, for by this cause expectation is sure to be aroused to such a degree as to render it impossible of fulfilment even if the intrinsic merits of the discovery be such as to entitle it to a high place in the estimation of the public. In so far as its merits fall short of these unreasonable expectations, the invention suffers. A feeling of disappointment far out of proportion to that which is justified is sure to be experienced by the public, and Dr. Bell's excellent paper suffered badly from this cause. However much we may have been disposed to criticise the business methods of the G. E. Company, we believe we are entirely unbiassed as regards the scientific accomplishments of its staff of able engineers, and would as willingly award our meed of praise to Mr. Steinmetz, or Dr. Bell, or Prof. Thomson, or Mr. Rice, as to Mr. Kelly, Mr. Scott, or any other worker in electrical science. In the science of electricity we know no General Electric Company, no Westinghouse, no Stanley, no other electric company—they are all workers in the same great cause and have al worked great good, and this we hope to recognize whatever its source. In the fierce business competition which has existed among the various large electrical concerns in this country there has naturally arisen an intense professional rivalry which in so far as it has been professional has been healthy and salutary and conducive to the progress of the science as a whole. It was doubtless this competition and rivalry that added the great intensity of interest manifested in the paper, and which caused those present to hang intent on the words of the able representatives of the various great interests who took part in the discussion.

For ourselves we must confess to a feeling of disappointment in the system as a whole as described in Dr. Bell's paper. This disappointment does not extend to the paper itself, for that was one of the most finished efforts of a finished scholar, ripe in experience of the subject which he handled. It was, too, a paper far more moderate in tone than previous papers and the occasion had led us to expect from Dr. Bell, and it was this very moderation that constituted its greatest strength and charm. But to our mind it fell short of a convincing argument that there had been accomplished the great improvements that had been claimed. One of the main efforts of the friends of the system was to convince the public that the monocyclic system differed radically from any polyphase system—that its phenomena were not polyphase phenomena—that it was in fact a development *ab initio* of an entirely new system.

To this end Mr. Steinmetz very adroitly defined polyphase phenomena in a way that excluded entirely those of his own system. If his definition was legitimate, the case was of course proved, but we think his definition will hardly be accepted by the electrical world. At any rate, if there is to be a division on this question the question will still remain one dependent upon how we shall define the word "polyphase." It will not be settled by the merits of the system, as its friends would like to have it, but simply upon the preponderance of feeling as to the definition of a word already long in use and generally pretty intelligently used. It appears to us that Mr. Scott's definition is by far the better of the two, and very accurately defines the meaning as the word is used to-day by intelligent electricians the world over. With this meaning attached to the word—and it is the one which we approve—the monocyclic system is *not* an entirely new one as claimed, but simply a modification of existing polyphase systems. While this question may have great legal and scientific import, it has no bearing upon the economic value of the system, and this after all is what concerns the public at large.

As we now understand the monocyclic system, it is one involving a generator developing currents differing in phase—a conducting system of at least three wires and the usual reducing transformers. It seems to differ from the ordinary three-phase system in that but two currents, differing in phase, instead of three are transmitted —the third current being obtained by the combination of the other two. The transformers for lighting are connected across but one pair of mains. The third wire of the system is said to convey no energy, but the motor transformers are connected with this in order to give to the three-phased motors which are connected thereto a starting torque. The third wire performs service in starting up, but when full speed is attained it might be discontinued without injury to the system so long as favorable conditions are maintained. If, however, conditions arise whereby the motor would perform badly under the two-phase condition, the third wire still in circuit would come to the assistance of the machine.

It would seem that the monocyclic system requires quite as complex a generator as the two-phase—an entirely similar line system and a three-phase motor. There seems, therefore. to be no simplification in this over present systems. Rather the reverse, for the wires cannot be used indifferently for light and power—the third wire is sacred to power. Although it is claimed that this wire consumes no energy, it does not reduce the amount of copper elsewhere, and the energy wires must be amply sufficient to transmit the whole energy single phase. The extra expense for copper thus brought about appears, therefore, to amount to 25 or more per cent. of the whole amount required for single-phase transmission Comparing it with two-phase transmission, Dr. Bell described a method of the latter which no engineer using two phase would think of adopting as though the latter was standard. By making this comparison a considerable economy was indicated where in fact it does not exist. When his attention was called to this he had to admit that there was another method of two-phase transmission which required less than 73 per cent. as much copper as single phase, instead of 45 per cent. more as he had shown. Now this method is in fact the system in common use, as shown by Mr. Scott, who further stated that if the voltage were pushed as high on the two-phase as on the three wire single-phase plan, of which Dr. Bell spoke approvingly, the copper required would be only 36.4 per cent. of that of ordinary single phase.

Electricity to the Fore. The occasion of an Electric Light Convention is always one of rivalry among the electrical journals, when each attempts to present in the most attractive form its claims for superiority. Never before in the annals of electrical journalism has the result of such a contest been left so little in doubt as in the present case. Never before has the existing order of things been so completely reversed as was the case at the Cleveland Convention. Since the Washington meeting the arrogant *Electrical World* has seen every prop by which it has sought to bolster itself up knocked from beneath it, and its fall has been ignominious and deserved. Its claim to age has been so successfully disputed by at least two of its contemporaries that it has now been abandoned. Its claim to advertising patronage in excess of all rivals is now as baseless as its claim to general utility or gentility has long been. It attracted the least attention of all the journals at the Convention, as evinced by the numbers of its issue discarded at the hotels. In contrast with this, not a copy of ELECTRICITY was made improper use of. It created no litter, and the ash barrels and toilet rooms of Cleveland are free from its familiar colors. The avidity with which ELECTRICITY was sought for, and when secured preserved for future perusal and reference, was something unparalleled in the annals of electrical journalism, and even our most bitter competitors were forced to award us the palm. This is the merited reward of genuine worth. We have ever striven to give the public something that it wanted—we have tried to meet the demand. The *Electrical World* has tried to force the masses to accept its own standard. Public opinion is slow to crystallize, but give it time and its judgment is infallible. Its judgment at the Convention was so overwhelmingly in our favor as to be unmistakable, and virtue has at last received its due reward.

* * *

The Cleveland Convention. The Eighteenth Convention of the National Electric Light Association, at which was celebrated the tenth anniversary of its birth, went out in a blaze of glory which bespeaks a future of increased usefulness for the organization. What has been accomplished during its decade of existence was fittingly referred to in President Francisco's address. Just how far the Association has been contributory to this progress—unparalleled in the history of industrial life—it is impossible to state, but it goes without saying that it has been a most important factor. What its influence is to be during the next decade it is also impossible to foretell, but it will be largely of its own making. The conventions of an association such as this are necessarily largely creatures of circumstances. As the business aspects change, so must the character of the meetings, and it has been a matter of congratulation to all that the organization has been sufficiently flexible to rise to each occasion as it presented itself. Thus the policy of holding several meetings a year, which was doubtless wise in the earlier history of the Association, gave way to the single meeting. The character of the papers presented at once advanced to a higher standard, and each succeeding meeting since that held at Buffalo has marked a distinct progress in this direction, and the programme presented at Cleveland was as far in advance of that at Washington as that was ahead of the programme at St. Louis ,or that an improvement upon Buffalo. There have been exceptional papers at other Conventions, notably that of Mr. Scott at Washington, that have surpassed in importance any of those read at Cleveland, but never before has the programme *as a whole* reached the same standard of excellence as that of the one just presented. The Cleveland Convention, too, will go down to history as the *business* Convention unless it shall be eclipsed in this regard by those which are to follow. The Washington Convention marked the high-water record of attendance from abroad, but in attendance on the meetings its record was not one to be proud of. At the Cleveland Convention both the numbers from abroad and of those attending the sessions surpassed any previous record. Never before has the interest in the papers been so well maintained as at this last meeting, and this is a matter of sincere congratulation as showing what a good programme will do.

The proportionate decrease in attendance of Central Station men, however, was the occasion for remark and solicitude. It seems strange that those for whose especial benefit the Association was organized should by their absence indicate an apathy for that which should and does advance their interests to such an extent. It becomes imperative now to do something to increase the attendance of electric light men. A step in the right direction was the change of date of meeting to a time when local interests can better spare the services of those who have them in their keeping. The suggestions of Mr. Beggs—ill-timed and in bad taste—that a better attendance could be obtained by lowering the annual dues—met the reception that it deserved. If the value of these meetings to the Central Station man is not appreciated to the extent of the present dues, it will not be appreciated at any lower figure. This class of men will not attend because membership is cheap. They are not cheap men in any sense of the word, and Mr. Beggs's insinuations were not relished. To gain a better attendance of those engaged in the electric light industry the endeavor should be to make the meetings more interesting and valuable to them. Presenting a good programme of papers is not the only way to do this. More time must be given to discussion in which experiences can be exchanged. The weak point of the Cleveland programme was that there was too much of it. The papers could not be adequately discussed, and that is a fatal weakness. One good subject such as that of how to light large cities, which was practically not discussed at all, might well have occupied two whole sessions. From our own standpoint, more success will attend a curtailment of the papers and an extension of the discussions than in any other way.

Discussion is the very life of all bodies like the N. E. L. A.

In harmony there is stagnation, but in controversy there is music

Under the Searchlight.

Views and Opinions on Timely Topics.

The Robust Baby.

(From the Toledo Bee.)

Electricity is still in its infancy, and new uses for it are constantly developing.

Advertising Axioms.

(From Printers' Ink.)

It is true that advertising, as a general thing, does not sell goods, but it brings the buyer to the seller.

The general public is not a mind reader. If it does not know what you have for sale, how can you expect it to go ask for your goods?

* * *

They Imitate Their Superiors.

(From the Albany Argus.)

The General Electric Company lately came into possession of information which implicated several foremen in the various departments of its works at Schenectady in a systematic scheme of extortion exercised upon men employed under them. It is said that in many instances the foremen sold positions which their authority enabled them to bestow, and other cases are cited in which it is related that employees were forced to pay tribute to the accused men in order to retain their positions.

* * *

Who is Kicking?

(Advt. in Boston Dailies.)

Holders of General Electric Co., preferred and common, are invited to communicate with the undersigned, stating number of shares held.

Venner & Company,
Tremont Bank Building, 8 Congress Street.

* * *

THE KIND OF MAN HE IS.

When we were pursuing our investigation of the Electropoise we interviewed, in regular newspaper manner, a number of physicians and others upon the subject. Among those so interviewed was Dr. Henry H. Morton, of Brooklyn. He along with Dr. W. J. Morton, of New York, Dr. A. D. Rockwell, Dr. Cyrus Edson and others, wrote us letters on the subject which we accepted as being inspired by the desire on the part of those gentlemen to aid the cause of truth.

Dr. Henry H. Morton has now sent us his bill for $35 for advice and for the letter he wrote.

* * *

The Chicago office of the G. E. Company is said to have advanced to one Lester Hills, special agent, $2,500 on his note (which is still unpaid), money to be used by Hills in the attempt to elect himself alderman in the First Ward of the city of Chicago in 1893. He got sadly left, and the General Electric Company has the note as a remembrance. It ought to be itemized in their securities.

* * *

* * *

THE CONVENTION.

The appearance of Mr. H. L. Shippey in the lobby recalled those other days when the Old Guard were not yet scattered.

* * *

Among the Cleveland men who were in regular attendance none made more friends than Scott Hayes. He will have to come into the Association and be one of us.

* * *

If Mr. Beggs will keep his tongue unheard for a year, and his face unseen, New York will have the next meeting. No cause, however, can endure his advocacy.

* * *

Mr. B. E. Sunny was in attendance for two days in his usual urbane and courteous frame of mind.

* * *

From the eloquence displayed by Capt. Harry Adams when discussing Ft. Wayne apparatus, it might be guessed that the Phillips Wire had not entirely effaced the memory of his old connections.

* * *

The punch served by E. W. Little and his associates was as strong as the insulation on Interior Conduit.

* * *

The first thing Frank Brobst did the morning after Pudd'nhead Johnston's arrival was to order ten tons of coal.

* * *

An old New Yorker, now domiciled in Cleveland, whom all the boys were glad to see, was Mr. M. M. Hayden.

* * *

Mr. John I. Beggs has not lost his desire for notoriety. That there was anything sincere in his bellowing at Cleveland will not be believed by anyone who knows him. If his attack had not been so unjust it would have been funny. After being dropped as a deadhead, and with scarcely a right to the floor, his attempt to revolutionize the Association was at least out of place. But Mr. Beggs does not know when he is funny. If he had wanted to be truly interesting and create a sensation he would have told what he knows about the fire in the Edison Building in 1892, when so many rare documents were burned up. If Beggs will do this next year, Electricity will guarantee a large audience.

* * *

The facts are that the N. E. L. A. is conducted very well indeed; and had it not been for those who are now prominent in the management, especially Mr. George F. Porter, the Association would be dead now. There is room for improvement, and the management are at all times eager in their search for suggestions. As for running the Association cheaply, why should it be thought of? We are not cheap people; we do not want a cheap Association; we do not want a cheap Secretary.

* * *

WE MAINTAIN OUR RECORD.

(From "Electricity," Feb. 20.)

If there is one feature of Electricity which, more than any other, has contributed to its pronounced success, it has been the feature of giving ALL THE NEWS up to the hour of going to press.

Last March we were able through superior enterprise to present the epoch making paper of Mr. Scott, read at the Washington meeting, one week in advance of our contemporaries.

Elsewhere in this issue will be found Dr. Bell's paper on the Monocyclic System, read at Cleveland, printed in full, and with the accompanying diagrams.

Electricity is up to date.

Personal.

Mr. R. S. Stearns, formerly of the G. E. office in Cincinnati, has gone to New Orleans to take charge of the sales department of the Southern Electric Company.

The Columbia (S. C.) Cotton Company's new cotton mill at Columbia is equipped with an electric plant for operation. The electric current is derived from the water power of the Congaree River, and is conducted in underground conduits and across the river under the iron bridge from the place of generation to the mill, where a number of electric motors in the different rooms operate the machinery used in the manufacture of cotton cloth.

The Schafer-Heinemann Accumulator.[*]

BY A. M. GIBSON.

During recent years but little progress has, for a variety of causes, been made in the improvement of storage batteries. The difficulties to be overcome in themselves were not great, but until recently the incentive to inventors of high scientific attainments was lacking. Early adventurers in the field obtained so-called master patents, and these falling into strong hands gave a practical monopoly of the accumulator system.

These early patents were for the containing grids, or plates for holding what is called the active mass. A storage battery is an arrangement of positive and negative electrodes with capacity for storing oxygen and hydrogen in certain chemical combinations, with capacity under given conditions of converting the elements so stored into electric energy. Metallic lead in the shape of powder, or compounds of lead, were found, in combination with sulphuric acid, to afford the most efficiency.

The lead compound was made into a paste and was fixed to conductors, a leaden frame or grid, and thus an electrode was formed. These were fixed in a box and sulphuric acid was added in sufficient quantity to cover the electrodes. But to hold the paste to the frames or grids a binding agent had to be employed which was insoluble in sulphuric acid and incapable of being electrolyzed. Therefore, a great deal of useless, because non-conductive, material had to be employed. There was both bulk and weight and low efficiency. Moreover, the molecular action which took place by the chemical conversions occurring during charging and discharging caused expansion and contraction of the lead compounds—the active mass—and two things happened: warping or buckling of the plates or grids and disintegration of the lead compounds. In a relatively short time the electrodes were destroyed.

As the time for the expiration of the so-called master patents drew near more attention began to be paid to perfecting accumulators. At the same time the employment of electric energy for various purposes began to extend greatly, and a demand for serviceable and highly efficient accumulators was created. A new class of electricians had also been created—men who had received thorough scientific training and were well grounded in chemistry and the physics of electricity. Electro-chemistry, it must be borne in mind, is a science of recent development and is daily widening its field as trained experimentalists are enabled to prosecute systematic work. Pioneers like Davy and Faraday indicated many important discoveries, and their laboratory demonstrations elucidated general laws governing phenomena theretofore incomprehensible. But there is a wide region between the laboratory demonstrations and the practical working upon a commercial scale. For instance, the phenomena connected with electrolysis in all their variety were noted and explained by Faraday, but the realization of electrolytic decomposition of the halogen compounds upon a commercial scale—a vast and important field—is just beginning.

Foremost in the field of electro-chemical discoveries and useful application thereof since Faraday's time we must recognize the German school of chemists. Hertz, Helmholtz and Ostwald have been the great teachers, and their pupils form an active, numerous band of trained men, who are patiently attacking difficult problems by scientific methods. Empirical experimenting may accomplish great results, but in electro-chemistry the worker who can grasp the possibilities in the largest degree of the many reactions in organic and inorganic chemistry is the one most likely to achieve the greatest success.

As before stated, the earliest experimenters with storage batteries confined themselves to the paste compounds of lead oxides and fixing them in grids with a mechanical binding agent. They employed for the latter tar products dissolved in alcohol, gum arabic and other adhesive substances. Two German electricians—Schafer and Heinemann—struck out a new line about the same time that Clement Payen, a French chemist, began experimenting with storage batteries. These three inventors, in common with many others, endeavored to eliminate as far as possible what may be termed electrically inert materials in the construction of storage batteries. Two requisites in accumulators are necessary—an active mass of the highest efficiency in the least compass and great stability of this active matter. The French inventor sought to get these results by the use of chloride of lead, and the German inventors employed glycerates of lead. Practical results, in my opinion, prove that the Germans have achieved greater success than their French rival.

---

[*] From the *Engineering and Mining Journal.*

Stability is required to successfully resist all interior molecular as well as exterior mechanical influences, but at the same time this stability of the active mass must not be secured by making it so dense that the sulphuric acid cannot act upon each molecule. It is necessary that there should be a certain porosity, or rather a crystalline structure, of the active mass which will, with the action of the electric current, permit an endosmostic action on the molecules by the sulphuric acid. This is also necessary in order to increase the superficial area and thus give greater capacity both in reception and in discharge. Another important point is to avoid cramping the lead molecules. They must have room for due expansion and thus prevent bending, bulging or warping of the containing grids or plates.

Glycerine has the property of forming with lead oxide a compound which, according to the proportions of the components, will in a few moments set and become a stone-like material, this being due to the formation and intergrowth of the crystals of lead glycerate having the following composition: $PbC_3H_6O_3$.

The lead glycerate is by the action of an electric current, in the presence of a solution of permanganate of potassium acidulated with sulphuric acid, converted into a chemical compound of peroxide of lead and peroxide of manganese, i. e., a lead salt of manganous acid under simultaneous oxidation or decomposition of the glycerine. The following equation partly illustrates the reactions:

$$C_3H_8O_3+4KMn.O_4+2H_2SO_4=2K_2SO_4+$$
$$H_2C_2O_4+4Mn.O_2+5H_2O.$$

The electrodes can be made either wholly of lead glycerate or of the latter, and a carrier constructed of a conductive metal capable of resisting the action of sulphuric acid, as, for instance, a lead frame, grid or plate, the required form being given to either, after which the glycerate of lead is converted into a lead salt of manganous acid as above described, whereby the glycerine is oxydized, the peroxide of manganese separated, and a coherent plate consisting essentially of dioxide of lead and dioxide of manganese is obtained.

The glycerate of lead by itself is non-conducting, of great density and firmness, and offers great resistance to all chemical agencies. It is only by the combined effects of the electric current and the sulphuric acid and alkali-permanganate that the chemical is affected—the glycerine being dissolved out and the remaining body rendered conductive. The manganese molecule combines with that of the lead and forms the salt thus: $Pb.\ O_2\ Mn.\ O_2\ (Pb.\ Mn.\ O_4)$.

If the electrodes are formed with carriers, the glycerate of lead is introduced into the lattice work, or grids, in its soft state, and crystallization takes place, and to obtain a transformation and get a conducting carrier, or material purely active, the plates are immersed in sulphuric acid to which has been added permanganate of potassium (the latter proportioned to the size of the plates), and then the electric current, in combination with the acid and permanganate of potassium, effects the desired transformation. The glycerine is oxydized away from the positive plates and the manganese enters and combines with the lead molecules.

With the negative plates the process is reversed. In the place of oxydation a reduction of the glycerate of lead is obtained and a pure, spongy lead results. The electrical formation of the electrodes requires from 12 to 24 hours.

The plates thus produced are now put together in the usual manner and charged. In this process peculiar phenomena make themselves manifest. In charging the accumulators the plates show red coloring, and in discharging they become colorless. The cause is found in the fact that in charging the manganese is freed from the lead by the superfluous oxygen and the hyper-manganic acid is dissolved, while it is bound up in the discharge thus:

$$Pb.\ O_2\ Mn.\ O + H + O_2=Pb.\ O_2 + H\ Mn.\ O_4.$$

Thus there exists in the electrode a conditionally bound separable salt which does not, however dissolve as salt of the acid of the electrolyte, but as an independent acid.

The manganese has a double function: 1st, it is intended to heighten the electromotive power given off by the change of the hyper-oxide of lead to sponge lead; and, 2d, it is intended to make room for the swelling of the molecules of lead through the absorption of oxygen, which in turn takes place in charging and the dissolving into hyper-manganic acid. In the discharge it returns to its old place; thus, in a sense, filling the free space as a sort of mechanical prop.

In this manner Schafer and Heinemann solve, by the most simple means, the task of finding room for the extension of the hyper-oxide of lead, same time the diffusion of the sulphuric acid is largely extended and the superficial area much enlarged. The discharge can be carried to the limits of all that is possible, i. e., even to short circuit, without injury to the battery.

One fact appears specially worthy of mention, viz., the growing together as it were into one body of the active matter with the lead lattice or grids, which consists of a legation of antimony of lead. This embodying is so dense that it shows on close observation a purely crystallic fusion, and a separation of matter and plate can only be achieved by a violent mechanical process. The absence of any mechanical binding material heightens, to a large degree, the electrical performance of the lead molecules. Thus an almost theoretical using up is obtained.

Meantime the interior resistance has become a matter of no importance through the purity of the substance used.

That under such circumstances the power of this accumulator is unequalled must appear self-evident even to the eye of the layman.

But these are the facts: Per 2 lbs. weight of plates it gives 17·6 ampere hours with a discharge of 2 amperes for same weight.

The only other accumulators which approach in efficiency the Schafer Heinemann are the chloride accumulators of the Electric Storage Battery Company of Philadelphia; the chloride giving per 2 lbs. of plates 11 to 13 ampere hours by a discharge of 1·1 ampere. The superiority of the Schafer-Heinemann accumulator over the chloride is thus apparent. The Schafer-Heinemann compares still more favorably with the Tudor system, giving a six-times better result than the former.

Still more remarkable is the mechanical effect between charge and discharge, as the following shows:

Loss of watts in the Tudor,	25 %	to	40 %
Loss of watts in the Chloride,	15 %	to	25 %
Loss of watts in the S.-H.,	1.4 %	to	5 %

The Imperial German Institute of Charlottenburg, under the presidency of Helmholtz, says in its report:

"The change of tension was the normal one as in lead accumulators, and showed the greatest regularity and absolute agreement in all trials with even currents.

"Crumbling or falling off of the matter, bents, bending or bulging, or any other changes in the plates have in no case been noticed."

The Tudor system, with accumulator weight of 3,000 kg., will propel a total weight of 10,000 kg. with a velocity of 10 km. per hour for 2¼ hours = 40 car km. The Schafer-Heinemann system, with accumulator weight of 2,500 kg., will propel a total weight of 12,000 kg. with a velocity of 20 km. per hour for 17 hours = 160 car km.

The following data is taken from the actual working of a tramway from Lichterfelde to Steglitz, near Berlin, which I have personally examined, the tests being made under my supervision.

The line is 2·9 km. = about 2,950 yards in length. Gradient, n=1·21, 2, i.e., 8·25 yards per 1,000. Velocity, v=12 km. per hour, i. e., 3·3 meters per second.

The tests were the simultaneous working of four cars, without tender. Number of seats 32. Time of running 5 minutes. (Herbrandt's car, drawing No. 1,025, 20 persons seated and 12 standing.) An allowance of 15 kg. friction resistance per ton was made. Weight of car on the horizontal=G., consisting of weight of car, 4,500 kg.; motor, 2,250 kg.; accumulator, 2,550 kg.; 32 passengers at 75 kg. each, 2,000 kg. G=11,700 kg.=11·7 tons. N=number of horse powers to overcome the resistance. N=(15+8·25) × 11·7× 3.33÷75=12·07 H. P. per car.

In the course of the run the resistance diminishes through the living force or the momentum of the car, and thus the drawing power amounts to only 2·75 H. P. The average drawing power thus amounts to about 4 H. P. The battery is size D 7 of the Schafer-Heinemann patent.

For each car a tension of 300 volts is assumed, i. e., 150 cells per car. Dimensions per cell: 140 mm. length, about 5 in.; 150 mm. width, about 5¼ in.; 350 mm. height, about 1 ft.; weight, 17 kg.; capacity, 245 amp. hours by 10·5 amperes discharge; 125 amp. hours by 42 amperes discharge; the average discharge is 4 H. P., or 4.736 =2,944 watts, or, with 300 volts tension, 2,944÷300=9·81 amp. or 10 amp. roundly. Thus one charge would suffice to run the cars for 24.5 hours.

As already mentioned, the train was run with a velocity of 12 km. (about 7 English miles) per hour, or 5 minutes per km. The whole of the journey of 2·9 km. is therefore 2·9×5=14·5 minutes. Return journey = 14·5 minutes. Two stoppages = 10 minutes. Total duration = 39 minutes from start to return with an 18 hours' service, 18×60÷39 = about 28 trips per car per day. Thus each car would run 28×2·9×2= 162.4 km. per day, and the 4 cars 4×162·4 = 649·60 or 650 km. per day.

For the working 4 cars were used, and consequently 4 accumulator batteries. Two additional should be in reserve in case of accidents.

For 4 car batteries at 300 volts = 150 cells at 245 A. H. Of the 245 amp. only 180 are used, as there is an 18 and not 24 hour service. The batteries are charged in 5 hours. They are placed in 4 parallel rows, i. e., 4 rows à 300 volts. The row with 36 amp. = 4 × 36 = 144 amp.

In the course of charging the tension of the accumulators increases from 2 to 2·5, or from 300 to 375 volts. Consequently an engine of 375 volts and 144 amperes is required, or 374×144=54,000 watts, or 54,000÷700 = 77·14 H. P. per 5 hours, or in round figures 778 H. P. = 390 H. P. hours.

A 78 H. P. engine requires 78 S. M. heating space (tubular boiler system). 1 H. P. requires 13 kg. steam per hour. Thus, use of steam per charge of 5 hours' duration : 78 × 13 × 5 = 5,070 kg. One kg. coal steams 8·5 lbs. water; thus, use of coal per day, 5,070 ÷ 8·5 = 596·4 kg. coal per 650 km. Use of coal per km. 596·4 ÷ 650 = 0·92 kg. coal. The four accumulator batteries cost 8 250 marks, or about £412.

Supposing an accumulator has to be renewed after having run, a, 118,552 km.; b, 177,828 km.; c, 237,104 km.

As every car runs per day 162·4 km.; this would work out as follows: a, 118,552 ÷ 162·4 = 730 days = 2 years; b, 177,828 ÷ 162 4 = 1095 days = 3 years; c, 237,104 ÷ 162 4 = 1460 days = 4 years. Renewal expenses would therefore be as follows: a, 8,250 ÷ 730 = 11·31 m. = 11s. 3d. about; b, 8,250 ÷ 1,095 = 7 53 m. = 7s. 5d. about; c, 8,250 ÷ 1,460 =5·66 m. = 5s. 6½d. about. Taking an average price of 21·5 marks per 1,000 kg. coal, a high price, we get 1,000 ÷ 21·5 = 46·51 kg. coal for one mark.

A daily deterioration of the accumulator under supposition a to the value of 11·31 m. would equal a quantity of coal = 11·31×46·51 = 526·03 kg. coal per car and 162·4 km. = or per car and km. = 526 03 ÷ 162·4 = 3·25 kg., i. e., deterioration of accumulator per km.: Add a 3 25 kg. coal; add b 2·17 kg. coal; add c 162 kg. coal. To these figures must be added the use of coal by the stationary steam engine of 0·92 kg. per km.; a 0·92 + 3·25 = 3·17 kg. coal per km. and car = 8,965 pfgs.; b 0·92 + 2·17 = 3·09 kg. coal per km. and car = 6·64 pfgs.; c 0·92 + 1·62 = 2·54 kg. coal per km. and car = 5·46 pfgs.

COMPARATIVE TABLE OF COST OF WORKING TRAM LINES.

The expense, inclusive of repairs, per car kilometer is as follows:

Kind of propelling.	Cost.	Authority.
I. Horse cars....	21 pfennigs per car km.	Hamburg tramcars' report for 1887, their cheapest year.
II. Steam cars...	14·6 pfennigs per car km.	Line Lichterfelde—Custom House.
III. Electric trolley system..	11.56 pfenn's per car km.	Line Halle at Saale, built by Berlin General Electric Co.
IV. Electric system by accumulators....	(a) 8·965 pfennigs (b) 6 64 " (c) 5·46 " per car km.	Line Lichterfelde Steglitz.

Judge Henry has dissolved the injunction against the Citizens' Electric Light Company brought at Terre Haute, Ind., by the Terre Haute Electric Light Company, which had obtained a temporary restraining order against the Citizens' Company erecting poles in the streets for lighting purposes. The latter company, of which Russell B. Harrison is president, has a contract to light the city of Terre Haute for five years.

THE CLEVELAND CONVENTION.

Tenth Annual Meeting of the N. E. L. A.

THE PROCEEDINGS IN DETAIL.

A Good Programme and a Large Attendance.

[STAFF REPORT OF ELECTRICITY.]

BANDED together to extend the knowledge of the science of commercial lighting, the members of the National Electric Light Association met in Annual Convention at Cleveland, O., at 11 A. M. on Tuesday, 19th inst., with President M. J. Francisco, of Rutland, Vt., in the chair. The place of meeting was the Army and Navy Hall, a location convenient to the headquarters of the association—Hollenden Hotel—and admirably adapted in every way to the purposes.

When the President rapped for order he faced probably the largest gathering that was ever witnessed at an opening session of the Association, the hall, capable of seating about 800, being nearly full. Among the number of non-members of the Association who graced the occasion were a large number of ladies, the wives, daughters and sweethearts of the members, and some of the ladies of Cleveland who were assiduous in their attentions to the visitors, and who throughout the Convention so successfully catered to the entertainment of their lady guests as to make this meeting a long-to-be-remembered one.

TUESDAY MORNING'S SESSION.

After a few preliminary remarks by President Francisco he introduced the Hon. Robert Blee, Mayor of Cleveland, who in a few brief and well-chosen words welcomed the members of the National Association to the city of Cleveland.

He was followed by Mr. James M. Hoyt, who was introduced as "the silver-tongued orator—the next Governor of Ohio." Mr. Hoyt is a master of elocutionary grace and held his auditors' attention to the very close of his all-too-brief remarks. His speech was also one of welcome. It was interspersed, however, with many witty allusions to electrical matters in general, and in one case it was at the expense of a contemporary. He said: "I was reading yesterday in one of your electrical journals something which caused a feeling of regret, and it seemed to me as if now I had become like the child who learns that Santa Claus is a myth and loses all faith in revealed religion. I was reading in one of your electrical journals yesterday that electricity could no longer be scientifically defined as a viscous fluid. The statement was that it is two fluids, one positive and the other negative—I want to quote from the article correctly—*attracting each other and repelling themselves*, whatever that may be; or at any rate all the results of my careful scientific research have been swept away with a single sentence."

This caused considerable merriment among all but those connected with the paper at whose expense the joke was made. His complimentary allusions to Mr. Brush were enthusiastically received by the audience, and paved the way for the next speaker, who spoke as follows:

Mr. Brush's Remarks.

Mr. President, Ladies and Gentlemen: A few days ago I was asked to make some remarks on this occasion concerning the early history of electric lighting from my own standpoint. Now, as most of you are aware, I retired from the electrical business several years ago to give my competitors a chance on the field. (Applause.) I therefore objected that this ancient history was forgotten and buried, and I pleaded that I could not spare time to take it up again and polish up the bones, and arrange them in sequence, and articulate them, and make the whole thing presentable. I really cannot afford to let you go, now that you are here, and I will say a few words.

I will begin by calling your attention to the fact that dynamo-electric machines for electroplating antedated by a considerable period the use of such machines for lighting purposes. This is interesting from a historical standpoint, because when I invented compound field winding for constant potential, now so generally used in lighting and power transmission, I applied it first to plating machines. That, I believe, is not generally known, and may therefore be interesting. Some of you will remember that all of the early Brush arc lighting machines were single lighters. Two of these machines were exhibited in the summer of 1877 at the Franklin Institute in Philadelphia. My two friends at the left (Messrs. Houston and Kennelly) will remember all about it. It was soon after that when we sold a single lighting machine to Dr. Longworth of Cincinnati. This was one of the very first, if not the first, sale of a Brush arc lighting machine. It was late in 1877 or the very beginning of 1878, and the Doctor paid for it—paid cash for it like a little man. I hear these things are done differently now. (Applause and laughter.) At any rate I went down to Cincinnati to show the Doctor how to run that machine, and one evening while I was there he exhibited the light from the balcony of the building in which he lived, on one of the principal streets. It was a 4,000 candle light and of course it attracted a large crowd of the natives, and every man in that crowd was ready and willing and anxious to tell his neighbors all about it. I mingled in the crowd for a time to hear the comments. I found one man who had collected quite an audience about him. He called attention to the solenoid at the top of the lamp. He said: "That is the can that holds the oil," and speaking of the side rod of the lamp, "that is the tube which conducts the oil from the can to the burner." He did not say anything about electricity at all—a little oversight that was not noticed by his hearers and it was all right.

These early single light machines were quickly followed by two and four light machines; that is to say, machines adapted to furnish two or four separate distinct currents, each adapted to run a single arc light. Several of these machines were sold during the season of 1878 for lighting stores and shops. Among others, Mr. Wanamaker, of Philadelphia, bought a number to light his store. One of the earliest of these four-light machines was exhibited at the works of the Union Steel Screw Company in this city to a number of invited guests. One gentleman on that occasion looked the whole apparatus over very carefully, perhaps a half hour, sized it up, and then pointing to the line wire he said to me: "How large is the hole in that wire that the electricity flows through?" (Laughter). Another gentleman, one connected with the screw company, observed the machine running for perhaps five minutes in complete silence. Then he had fully digested the whole thing and was ready to tell me all about it. He said: "The electricity in that thing is generated by that revolving business there rubbing the air up against those iron blades (meaning the magnets), just as you get sparks when you rub a cat's back." I raised the objection that while that was a good theory, it did not fully meet the facts, but he would not hear anything from me. He said: "The whole thing is plain. If you should run that machine in a vacuum where there is no air you could not get any electricity." His ignorance was so blissful that I thought it would be folly to enlighten him and did not try to do so.

The year of which I am speaking, 1878, was memorable in the history of electrical lighting. It was during that year that I had the great pleasure and good fortune to invent and develop and commercially introduce the modern series arc lamp with the shunt coil. It was this invention—I am sure you will all agree with me—which first made arc lighting from central stations commercially possible, and I think it may justly be considered as marking the birth of the electric lighting industry of the world to-day.

One of the first instances, I think quite the first instance, of the use of arc lighting for purely commercial purposes was in our little public square in this city. Twelve lights were carefully installed in the park on high ornamental poles. The lamps used were of the ordinary so-called 2,000 candle power. In this connection it will be remembered that a professor in New York once said he imagined the electrical companies arrived at the 2,000 candle power by measuring it north, south, east and west, giving 500 each way, and added them all together. That measurement was taken in the interest of the gas company, as I have learned. While we were installing this plant in the public square, a great deal of interest was manifested in the installation by the public, and on the occasion of starting the lights our little park was packed from side to side, and it was evident that many of the people expected a blinding glare of light, as evidenced by the fact that many of them had provided themselves with colored spectacles or smoked glass. Of course, there was a general feeling of disappointment at first in this respect, although every one was ready to admit he could read with perfect ease in any part of the square. After a few weeks, when the novelty had worn off, and the people had got tired of staring at the arcs and had time to see how nicely the little park was lighted, the general verdict was that those electric lights in the park were a pretty good thing after all, and that is the general verdict everywhere.

Of course we had lots of trouble in the early days with carbons. The history of the carbon business is peculiar. Our first carbons were crooked, of course, and were soft, and had high electrical resistance, and burnt out rapidly, and were very expensive. To decrease the electrical resistance, and prolong the life of the carbons, we electroplated them with copper, which is still done. This little scheme of covering the carbons with just enough and not too much copper was the only easy invention that it was my good fortune to make, and it paid fairly well, considering the effort involved, which was mighty small. It yielded, if I remember, something like $150,000 in cash on royalties before the bottom fell out of the carbon business. They were sold at the rate of $240 a thousand. I say at the rate of $240 a thousand, because nobody ever thought of ordering a thousand carbons at once. They could not use them up in a generation. Fifty or a hundred were considered a fair order. As the business increased a little we were able to reduce the price of the carbons, and we did reduce it one step to $150 a thousand. It was at a loss for a time, but then we held our own, and afterwards made a little money. We subsequently reduced them from $150 to $62.50, on the theory that cheaper carbons would stimulate the growth of the electric light industry, and our theory was proven correct. Their use was stimulated, and the business increased enormously, so that while we lost money on the carbons for a good while at that price, later we made a handsome profit at that price. Others seemed to grasp the situation about that time, and competition sprang up, and it knocked the profits of the carbon business all to pieces. I presume now you can get your carbons for next to nothing a thousand, with "a beautiful chromo in each box"; and I have no doubt if you insisted you could get a nice gold frame for each of the chromos. This is a pointer for you.

As to electrical lighting at the present day, most of you know more about it than I do, for I have been accumulating rust for several years, and will not attempt to tell you anything about it, but will simply thank you for your attention.

President Francisco's Address.

After the applause following Mr. Brush's address had subsided, President Francisco delivered his address which was short and to the point. He recalled how ten years ago the Association was formed in Chicago by a few gentlemen who believed in the future enlargement and

success of the electrical industry. This faith had been justified by time. The Association, which began with a very limited number of bold spirits, now embraced the whole country, and had in fact invaded the Queen's dominions on the north, and appropriated one of her subjects (Mr. Nicholls) as its second vice-president. The Association had also, he said, gained two other faithful allies, viz., the ladies and the press. It had attracted to its membership some of the most talented of England's scientists, and had brought within its keeping and solicitude an industry which included 2,500 central stations representing an invested capital of over $300,000,000, not including 7,500 isolated plants valued at $200,000,000 more. Besides these there were to-day 1,000 electric railways in operation with 10,000 miles of track, and assets amounting to $600,000,000—all or nearly all of this being the growth of the last ten years—the measure of life of the Association.

Having congratulated the Association that it was the representative of this vast industry which had revolutionized the civilized world, he endeavored to gaze into the future to discern what the next ten years might have in store. He then turned his attention to the immediate wants and conditions of the Association. Attention was first called to the growing idea favorable to municipal ownership. This, he thought, should be combatted by the Association by every means in its power.

An amendment to the constitution, changing the time of meeting to a more convenient and seasonable time of the year, was recommended, and then he turned his attention to the relations between central station companies and the manufacturers. Here he spoke in no uncertain terms, and it is safe to say his words met a most responsive chord in the hearts of his auditors. He said:

The Relations Between Central Station Companies and Manufacturers.

> The relations between central station companies and manufacturers have been discussed by this Association at every Convention. The time has arrived when the plan adopted by manufacturers for destroying the business of the local company by establishing competing plants in places where there is only business sufficient for one must be abandoned. This has been done with the intention of compelling the local company to either buy them off or see their own business ruined. The infamous scheme of forcing a sale of apparatus for a city plant by representing to city officials that the price charged by local companies is far in excess of the cost if the city owned its own plant, needs the searchlight of electricity thrown upon it by this Association. This is a question of vital importance to every central station in the United States, for sooner or later their own business will be attacked, and it may be through the influence of the very manufacturers whose apparatus they are using.

These ringing words aroused an enthusiasm among his auditors and were a most stinging rebuke to our milk-and-water contemporaries who have not had the manhood to raise their voices against the great octopus which, though dying and almost harmless now largely through ELECTRICITY's course, once threatened to strangle in its tentacles all which could not be bound to its service. The President didn't say so in so many words, but he implied what every central station man knows, and what every supply man knows, that ELECTRICITY was the only friend the electrical industry had during those dark hours of trial.

Lest our thick-headed contemporaries should not understand clearly what he meant, and that he meant us, the President said this business needed the "searchlight of electricity thrown upon it." We were modestly pleased with this official recognition of our humble efforts, and beg to assure the speaker and the other members of the Association that ELECTRICITY's searchlight *will* be turned on those dark methods and that thereby those dark spots shall be made light.

TUESDAY AFTERNOON SESSION.

The session was called to order at 2.30 P. M., and Mr. Nelson W. Perry, E. M., read his paper entitled "The Storage of Energy Essential to Economy of Working in Central Stations," in which he compared the results actually obtained in central station practice with those obtained by the same machinery working under a constant load, the discrepancy between the two showing the necessity of equalizing the load by means of storage of energy of some kind. He then discussed battery storage, the three methods of thermal storage, and gas storage and gas engines, comparing the results obtainable by these methods with each other. The comparison was unfavorable to battery storage, and this aroused the ire of those interested in the storage battery, who, in the person of Mr. Lloyd of the Chloride Accumulator Company, criticised the paper somewhat severely and heatedly. His main point of attack was that the price which Mr. Perry estimated the storage battery at was out of all proportion to the real price, and, unfortunately for him, implied that if Mr. Perry had gone to responsible parties for his data he could have gotten them correct.

Mr. Perry created quite a titter in the audience by replying that he had supposed he had gone to reliable parties for his data, since he had gone to the company that Mr. Lloyd represented. They had made him an estimate on an eight-hour discharge which was larger than he had given for a twelve-hour discharge. Mr. Lloyd questioned whether Mr. Perry had gone to his company, but this was settled by Mr. Perry's statement that he held in his hand the letter containing the estimate.

Mr. C. L. Edgar, of the Boston Edison Station, arose and said that he had come in near the end of the paper, and therefore could not discuss it intelligently, but he thought Mr. Perry's figures were too high, mentioning what batteries cost in his station. It turned out, however, that his own figures were considerably higher than Mr. Perry's, and that he was erroneously discussing an entirely different question from that at issue.

Prof. Wilbur M. Stine, of Chicago, read a somewhat elaborately prepared discussion, in which he took pretty near the same ground as Mr. Perry. Mr. Peter Wright also read from manuscript on the satisfactory performance of the battery plant at the Germantown station, which corroborated Mr. Perry's position. Mr. John A. Seely was the most active participant in the discussion next to Messrs. Perry and Lloyd, and cited several cases where the storage battery had proved a failure. Prof. Richards also spoke of a failure within his experience, but did not cite it as a criterion for the present day since a number of years had elapsed and great improvements had been made since then. He could not say from his own knowledge whether or not a storage plant would to-day be a failure under otherwise similar conditions.

The President interrupted the discussion at this point, announcing that on account of the fact that Prof. Houston had to leave on the evening train it was desirable that he be given an opportunity to read the paper on "A New Method of Measuring Illumination," by himself and Mr. A. E. Kennelly. He considered Mr. Perry's paper of such importance, however, that he would merely postpone its further discussion to a future time, when it would be taken up again.

Prof. Houston next read the paper on the above-named subject and exhibited an instrument, invented jointly by himself and Mr. A. E. Kennelly, by which the illumination at any point of a room could be determined with approximate accuracy by direct methods. This instrument he called an "illuminometer."

The paper was discussed by Prof. Elihu Thomson, Mr. C. D. Haskins and Mr. A. E. Kennelly.

After reading letters of regret for their inability to be present at the Convention from Prof. Silvanus P. Thompson, of England, and Messrs. Nikola Tesla, Marsden J. Perry, George Westinghouse, Jr., Chas. W. Price, Charles A. Coffin and Governor McKinley, President Francisco extended invitations from the telephone and street railway companies of Cleveland to the members to avail themselves of their service free of charge.

The National Electric Light Association is in the same position as Mr. Hill. It seems that letters had been written to President Cleveland, but he paid no attention to them. It remains to be seen whether or not the sequel will be the same. Should President Cleveland invite the Association to dine with him, as he did Mr. Hill, doubtless the Association will do exactly as Mr. Hill did.

WEDNESDAY MORNING.

The first order of business was the report of the Committee on Finance, read by Mr. John A. Seely, Chairman. This showed the Association to be in a highly satisfactory condition—that is, it was satisfactory to everyone but Mr. John I. Beggs, of Cincinnati, who, as representative of the Harrisburg Edison Company, joined the Association in 1892, and had been dropped from membership for non-payment of dues and had recently joined the Association again, but who had never taken a prominent part, and who made a lamentable spectacle of himself and the collar he wears by an attack on the management of the Association. His particular point of attack seemed to be the Secretary. He saw no use for a salaried Secretary. His salary was too high anyhow. He criticised the account for stenographic work, etc., etc., and wanted to have the Association conducted after the manner of the Association of Edison Illuminating Companies.

It is needless to say that his remarks received as chilly a reception as Pudd'nhead did on his way to Cleveland and during his stay there.

The discussion of Mr. Beggs's position was growing somewhat heated when President Francisco put a stop to it, saying that it could go no further at this time, but would receive due attention in executive session.

Mr. W. E. Harrington then read a carefully prepared paper on "Correct Method of Protecting Electric Circuits." He advocated the use of electromagnetic cut-outs, giving a number of curves showing the effect of the time and current elements both in fuse and magnetic cut-outs, which indicated all the advantages of the latter. He then adverted to special methods by which the magnetic cut-out had been still further improved by reducing the time element and consequently the current element.

The next paper read was one by Mr. C. N. Black on "Large Arc Dynamos." This was a most important and timely paper, and deservedly attracted very close attention.

Mr. Black, after referring to the lack of improvement in and the low efficiencies of arc dynamos up to within recent date, compared the relative merits of the closed and open coil machines. Electrically, he expressed the opinion that the closed coil machine was the best, but practically the open coil was the best. He explained how the self-induction in the open coil machine, which had been pointed to as an evil by the advocates of the closed coil, was really an advantage, and purposely made larger for this reason. The advocates of the close coil type had asked the question, "what would become of an open coil machine with large output if the circuit should become suddenly broken?" He answered this by giving figures showing the rise of potential at rupture on circuits supplied by both types of machine under like circumstances. These figures showed that the rise in potential was *less* in the open coil type than in the closed coil type, and gave a very plausible explanation of the reason therefor. He thought that the limit to the number of lamps that could be safely put on a single circuit was considerably beyond even that now in use—120 to 125. It was limited by the possibilities of insulation against the higher voltages. He cited instances where, even in former times when the art of insulation was in its infancy, no inconvenience was experienced with higher voltages than those now used.

The demand now was for larger units, and this was admirably illustrated by Mr. S. M. Hamill, who, after the paper had been read, was called upon to make some remarks. This matter is of such great interest to Central Station men that we must refer them to future issues for the complete reports. We need add nothing further here to indicate the importance of the paper than to give the names of the others who discussed it, viz., Prof. Elihu Thomson, Messrs. I. R. Prentiss, T. Carpenter Smith and John A. Seely. Several other gentlemen desired to discuss the subject, but the hour being late further discussion was cut off.

Mr. John A. Seely then offered resolutions that the Cotton States International Exposition to be held at Atlanta be endorsed by the Association, and that it urge the attendance and cooperation of its members. This was passed unanimously and the meeting adjourned to meet in executive session.

WEDNESDAY AFTERNOON.

The programme stated that the afternoon session would convene at 2:30 P. M. It had been announced verbally by the President that Dr. Bell's paper on the Monocyclic System, which had been postponed by the non-arrival of the drawings in time for the morning session, would be taken up first in the afternoon. The people were on hand pretty promptly, since this paper was looked forward to with perhaps as much interest as any paper announced before the Convention, but in view of the limited time and the crowded calendar, a very annoying and regrettable delay of over an hour ensued before the paper was read. When it became evident that this delay was to be somewhat extended, Vice-President Nicholls proposed that the question "How to Light Large Cities" be taken up out of its order, and this was put as a motion. Upon being put to a vote a division was called for which resulted in a majority vote in its favor. This was a subject which might profitably have occupied the whole time of the Convention during *all* of the three days, and it had been arranged to have Messrs. Nicholls, Ayer, Huntley, Clark, Redmond, Peck, Lindsay and Morrison lead the discussion.

It would have been worth all the trouble of getting up the Convention to have heard these men discuss this question, but because of it having been borne out of time it fell flat. These names having been read over by the President, no one responded. Judge Armstrong rose to the occasion, however, and said that since there was no one to respond to the invitation to speak on "How to Light LARGE Cities," it would be in order to hear from some one who could tell how to light SMALL cities, and called upon Mr. Wilmerding (of Chicago) to tell them something of "How to Light SMALL Cities." [This town, by the way, is the one in which the story of Pygmalion and Galatea is always popular, because the hero's name suggests an industry that has made the city what it is.—Ed.]

Mr. Wilmerding responded gracefully. He couldn't tell how to do it from experience, because that same great genius which had devised the electric belt method of teaching electrical engineering, viz., the National School of Electricity, had also undertaken the job of lighting the village, and was charging more for the municipal lighting than his company was doing by private enterprise. Mr. Wilmerding did not actually refer to the National School, but he referred to the municipal enterprise, which in fact bears the same relation to legitimate private enterprise as the electric belt and the electropoise bear to legitimate electro-therapeutics.

After the conclusion of Mr. Wilmerding's remarks, Mr. Redman, who had come in in the meantime, gave a brief description of the service in Rochester.

By this time the preparations for Dr. Bell's paper had been completed and the author proceeded to read.

The Monocyclic System.

It will be remembered that *the* feature of the Washington Convention was Mr. Scott's paper on "Polyphase Transmission," in which was developed a practically new system of great prospective utility. This received such universal commendation at the time as to constitute the occasion a most distinct triumph for the Westinghouse Company, which by its brilliancy quite overshadowed for the time everything that had been done by the General Electric Company. Dr. Bell's paper was expected by friends of the G. E. Company to do for his company on this occasion what Mr. Scott's paper had done for the Westinghouse Company on the former occasion, and public interest was on the *qui vive* for the discussion which should follow. The keen rivalry which has so long existed between these two concerns was expected to reach a climax at that time, and the Hectors of both armies were present to do battle for their respective colors.

Mr. Kelly of the Stanley Company was the first participant in the discussion. He thought that the monocyclic system had come too late. Had it preceded the polyphase system it might have constituted a decided advance on existing practice, but coming as it did, after the latter had been introduced, it constituted in reality a step backward which the electrical interests would not be likely to take. It accomplished nothing that had not already been accomplished in a somewhat better and more complete manner.

Mr. Steinmetz of the G. E. Company, and the inventor of the monocyclic system, followed and endeavored to point out that the monocyclic system was a system *sui generis* and not in any sense a polyphase system or a modification thereof. In substantiation of his position he defined the meaning of "polyphase," and pointed out how that, according to this definition, his system could not possibly be brought within its meaning.

Prof. Elihu Thomson, of the G. E. Company, indorsed in a few words all that both Dr. Bell and Mr. Steinmetz had said and claimed.

Mr. Scott, of the Westinghouse Company, followed. Referring to Mr. Steinmetz's definition of polyphase phenomena, he said that one had a right to define them anyway he chose. If he was careful to define them in such a manner as to exclude the particular features of the monocyclic, as Mr. Steinmetz had done, then of course according to this definition the monocyclic phenomena were *not* polyphase phenomena. If, on the other hand, the definition included the phenomena and methods of action by which the results were actually obtained, then the monocyclic *were* polyphased phenomena and nothing else.

Referring to the diagrams and data of copper economy of the various methods of periodic current distribution presented by Dr. Bell, he showed that they were in some cases erroneous, and finally he criticised in detail the general economies of the system, which he characterized as but a modification of existing systems, possessing doubtful merits where it resembled them and marked demerits in the features wherein it differed.

Dr. Bell then replied somewhat briefly. The hour for adjournment having now arrived, further discussion was postponed.

As in the case of Mr. Perry's paper, there were many others than those who took part who desired to, and the disappointment was universal that the matter had to be dropped at this point. The hope that the discussion might be continued at one of the succeeding sessions was disappointed on account of the crowded condition of the programme and the backward condition of the calendar.

WEDNESDAY EVENING.

The only evening session of the Convention was that held on Wednesday to witness a practical demonstration of the protection of lines from lightning by means of lightning arrestors. On this occasion Mr. A. J. Wurtz repeated his lecture and demonstration, already fully described in these columns, to a most attentive audience. This lecture, which has been given at New York, Boston, Philadelphia, and in several cities of the West, is one of the most instructive as to the nature of lightning discharge and the means necessary for protection against surgings of this kind that has ever been brought before a popular audience, and has had an educational value of a high order.

THURSDAY MORNING.

After a few remarks from Mr. W. R. Gardener, of Pittsfield, on Dr. Bell's paper, President Francisco called for the report of the Committee on Data, which was read by the chairman, H. M. Swetland, of New York, and supplemented by Mr. Gardener with a description of the methods adopted by him in obtaining the data furnished from his station and the conclusions which he had reached from these data. These formed a valuable addition to the report and will deserve further notice at a later date.

Others who discussed this report were Messrs. Powers, Armstrong, Swetland, Jennings, Hadley, Burleigh, Barker and Ayer, the tenor of whose remarks was to place a high estimate upon the value of the report and to demand a continuance of the same.

Some of the gentlemen desired that the committee assist the central station men in collecting the data desired by indicating more clearly just what was desired.

In line with this Mr. Ayer offered the following resolution: "That the Committee on Data be directed to send out as soon as possible after the adjournment of this meeting blanks upon which records of central stations may be kept with full instructions how to make the returns." Carried.

The meeting then adjourned to executive session. At this session the report of the Committee on Relations Between Manufacturing and Central Station Companies was fully considered, and the following special committee appointed in connection therewith: Messrs. A. J. DeCamp, John I. Beggs, E. A. Armstrong, T. Carpenter Smith and F. Gilbert.

Messrs. Seely, Armstrong and Colburn were appointed a committee to nominate officers for the ensuing year.

Messrs. Ayer, Nicholls and Burleigh were appointed a Committee on Resolutions.

The constitution was also amended, providing for the holding of one meeting in each year in the month of May or June.

A motion was passed recommending that the next meeting be held in New York City.

THURSDAY AFTERNOON.

The next paper was one by Mr. L. B. Marks on "Arc Carbons and the Rating of Arc Lamps." In this and the discussion following, the rating of arc lamps by a watt standard was advocated, the variation of voltage of the various makes of carbons between hissing and flaming points was discussed, and the effects of variation in composition and structure upon economy of various carbons pointed out.

Prof. Thomas, of Columbus, gave some interesting results of tests made upon carbons obtained from a large number of central stations in Ohio at the Ohio State University. These tests were made for the purpose of getting at the facts as to the light actually given by the carbons. The point of the investigation was to determine how much variation there was in the candle power afforded by arcs which were maintained at an expenditure of a constant amount in watts. The figures given show a somewhat wide variation with practically constant consumption of watts, and led Prof. Thomas to conclude that a watt rating for arc lamps was simply taking a step in one direction which did not tend in any degree to remove the trouble—that it merely shifted the trouble from one basis to another.

He believed with Messrs. Houston and Kennelly that the proper basis for a contract between a municipality and a corporation was that of illumination solely.

He did not indorse Messrs. Houston and Kennelly's instrument for determining this illumination, however, as the principle upon which it was based had proved fallacious and unsatisfactory.

Mr. Ayer rather favored the watt rating, not as an ultimate resort, however, but as a step from something entirely indefinite to something that was definite.

Judge Armstrong took the same view as Mr. Ayer.

The report of the Committee on Rules for Safe Wiring was then presented by Mr. Ayer, and consisted of a recommendation that the present rules be approved and continued.

Following this the subject of the Welsbach light was discussed by Messrs. Gardener, of Pittsfield; Edgar, of Boston; Cairnes, of Memphis; Seely, of New York; Peck, of Brooklyn; Armstrong, of Camden; Stetson, of New Bedford; Mr. Francisco, of Rutland, and Mr. Corriveau, of Montreal. All of these gentlemen confirmed the position taken by ELECTRICITY on this subject, that the competition while ephemeral must be met, and that when met by good service would be short lived.

The following resolution, offered by Mr. James I. Ayer and seconded by Frederic Nicholls, was then passed:

"That the thanks of the Association are hereby tendered to Mrs. Sidney Short and the ladies of the Local Committee, to Mr. Wason and the gentlemen of the Reception Committee, the Cleveland Telephone Company, the Long Distance Telephone Company, the Cleveland City Railway Company, the Cleveland Electric Railway Company, and the gentlemen of the local press.

"The many courtesies extended to the visiting members have been fully appreciated, and the result has been that this Cleveland meeting will be remembered as one of the most pleasant, from a social standpoint, and also one of the most interesting and instructive, in the history of the Association."

The Committee on Nominations presented the names of the following gentlemen:

President—C. H. Wilmerding, Chicago, Ill.; First Vice-President—Frederic Nicholls, Toronto, Canada; Second Vice-President—E. F. Peck, Brooklyn, N. Y.

Members of Executive Committee—E. H. Davis, Williamsport, Pa. (one year); W. R. Gardener, Pittsfield, Mass.; George A. Redman, Rochester, N. Y.; J. J. Burleigh, Camden, N. J.

The gentlemen were duly balloted for and elected.

Mr. Armstrong—"I move, with the unanimous consent of the members, that the next annual meeting of this Association be held in the month of May or June, as selected by the Executive Committee, in the year 1896." Carried.

On motion adjourned.

THE SOCIAL SIDE.

The entertainment of the guests by the citizens of Cleveland was all that could be desired. Carriages were provided at stated times for those who wished to visit any of the points of interest.

On Wednesday evening an enjoyable reception was tendered at the rooms of the Art Club, which was well attended.

The social event of the meeting, however, was the reception given to the ladies by Mrs. Sidney Short and her friends. Reserved for the fair sex, it cannot be described by us—in print.

THE SPECIAL TRAINS.

Both New York and Chicago sent goodly delegations by special train. The New York party was in charge of Mr. C. O. Baker, which means that everyone enjoyed himself in the customary manner. This train left New York at 9.30 A. M. and arrived in Cleveland about 12 at night, picking up the delegations of the interior cities en route. The roster was as follows:

Ayer, Jas. I., Marks-Ayer Electric Co., New York.
Alberger, L. R., Henry R. Worthington, New York.
Adams, H. C., Phillips Insulated Wire Co., New York.
Almstead, J. A., Citizens' Light and Power Co., Rochester, N. Y.
Baker, Jr., C. O., Baker & Co., Newark, N. J.
Bergtheil, Edward, electrical engineer, London.
Bakewell, Allen C., Interior Conduit and Insulation Co., New York.
Brady, F. H., Specialties, New Britain, Ct.
Burke, J., Herrick & Burke, New York.
Baird, M. E., Eddy Electric Manufacturing Co., New York.
Badger, F. H., Montmorency Electric Power Co., Quebec.
Belden, A. J., Belden & Seely, Syracuse, N. Y.
Burns, Charles T., Rochester, N. Y.
Crouse, J. B., Crouse-Tremaine Carbon Co., Fostoria, O.
Coles, Stephen L., "Electrical Review," New York.
Chesley, C. C., Stanley Electric Mfg. Co., Pittsfield, Mass.
Carpenter, C. E., Carpenter Enamel Rheostat Co., Hoboken, N. J.
Coughlan, W. F., Worcester Electric Light Co., Worcester, Mass.
Cram, H. B., Bernstein Electric Co., Boston, Mass.
Colvin, F. R., Interior Telephone Co., New York.
Corriveau, A. J., Montreal.
Douglas, S. A., Ft. Wayne Electric Corporation, New York.
Duffie, Jr., New York.
DeRonde, F. S., Standard Paint Co., New York.
Davis, H. M., "Electric Power," New York.
Fairbanks, H. H., Worcester Electric Light Co., Worcester, Mass.
Francisco, M. J., Rutland Electric Light Co., Rutland, Vt.
Francisco, Don C., Rutland Electric Light Co., Rutland, Vt.
Francisco, Jr., M. J., Rutland Electric Light Co., Rutland, Vt.
Flanagan, Thomas J., Rutland Electric Light Co., Rutland, Vt.
Gardner, F. F., Newark Electric Light and Power Co., Newark, N. Y.
Gilbert F. A., Boston Electric Light Co., Boston, Mass.
Gates, J. J., Perkins Electric Switch Mfg. Co., Hartford, Ct.
Greene, B. E., "Electricity," New York.
Gallaher, C., National Conduit Mfg. Co., New York.
Hambey, J. D., Beacon Vacuum Pump and Electrical Co., Boston, Mass.
Heinrich, R. O., Weston Electrical Instrument Co., Newark, N. J.
Hart, Gerald W., Hart & Hegeman Mfg. Co., Hartford, Ct.
Harrington, F. W., India Rubber and Gutta-Percha Ins. Co., New York.
Huntley, C. R., Buffalo General Electric Co., Buffalo, N. Y.
Hatch, E. D., H. W. Johns Mfg. Co., New York.
Herrick, A. B., Herrick & Burke, New York.
Herrick, Charles H., W. S. Hill Electric Co., Boston, Mass.
Higgins, E. N., Citizens' Illuminating Co., Rochester, N. Y.
Holmes, W. E., Newton and Watertown Gas Light Co., Newton, Mass.
Holtzer, Charles W., Holtzer-Cabot Electric Co., Boston, Mass.
Hine, Henry, Stanley Electrical Mfg. Co., Pittsfield, Mass.
Hotchkiss, , Electrical Engineer and Supply Co., Syracuse, N. Y.
Hinds, Syracuse N Y
Jones, A. J., Edison Illuminating Co., New Brunswick, N. J.
Johnston, W. J. "Electrical World," New York.
Kimball, General Electric Co., Boston, Mass.
Kelly, J. F., Stanley Electric Mfg. Co., Pittsfield, Mass.
Kittle, E. B., Pettingell-Andrews Co., New York.
Lindsley, S., Essex County Electric Co., Orange, N. J.
Little, E. W., Interior Conduit and Insulation Co., New York.
Leonard, H. Ward, electrical engineer, New York.
Learned, C. A., Hudson County Electric Co., Jersey City, N. J.
McIntire, C. H., The C. McIntire Co., Newark, N. J.
Martin, A. J., Complete Electrical Construction Co., New York.
Martin, T. C., electrical engineer, New York.
Mackie, C. P., Electric Selector and Signal Co., New York
Mackay, W. H., Imperial Electric Lamp Co., New York
McConnell, W. J., American Electric Mfg. Co., St. Louis, Mo.
Marks, L. B., Marks-Ayer Electrical Co., New York.
Marshall, Norman, Andover Electric Light Co., Andover, Mass.
Millett, C. W., Dolgeville Electric Light and Power Co., Dolgeville, N. Y.
McLaren, P. M., Abendroth & Root Mfg. Co., New York
McQuaide, J. P., National Conduit Mfg. Co., New York
Nunn, Paul N., San Miguel G. M. Co., Telluride, Col.
Newton, C. E., Jewell Belting Co., Hartford, Ct.
Osborne, W. F., "Western Electrician," New York.
Perry, Nelson W., "Electricity," New York.
Phipps, E. H., Connecticut Pipe Mfg. Co., New Haven, Ct
Peck, E. H., Citizens' Electric Illuminating Co., Brooklyn, N. Y.
Redman, G. A., Rochester Gas and Electric Co., Rochester, N. Y.
Pentz, James A., Philadelphia, Pa.
Phelps, Geo. M., electrical engineer, New York.
Purington, A. J., Stamford Gas and Electrical Co., Stamford, Ct.
Renehan, J. J., Specialties, New Britain, Ct.
Sachs, Joseph, electrical engineer, New York.
Seely, John A., Complete Electrical Construction Co., New York.
Stieringer, Luther, New York.
Shain, Charles D., Manufacturers' Agent, New York
Shaw, A. C., electrical engineer, Boston, Mass.
Smith, Geo. L.
Smith, J. Brodie, Manchester Electric Light Co., Manchester, N. H.
Smith, Harrison J., Edison Electric Illuminating Co., New York.
Swetland, H. M., "Power," New York.
Towles, C. L., Jewell Belting Co., Hartford, Ct.
Thomson, Elihu, Lynn, Mass.
Wood, E. E., "Electrical Industries," New York.
Wheeler, S. Bowman, Morris, Tasker & Co., Philadelphia, Pa.
Wintner, St. Louis, Brooklyn Electric Mfg. Co., Brooklyn, N. Y.
Wiley, Geo. L., Standard Underground Cable Co., New York.
Walter, H. H., American Carbon Co., Noblesville, Ind.
Welch, J. W., New York Central Railroad, New York.

LADIES.

Mrs. M. J. Francisco, Mrs. C. O. Baker, Jr., Mrs. G. A. Redman, Mrs. C. H. McIntire, Mrs. H. J. Smith, Mrs. F. S. DeRonde, Mrs. C. W. Millett, Mrs. W. J. Johnston.

The Chicago Special.

The list of the Chicago pilgrims is as follows, others who were not on these trains being listed elsewhere:

CHICAGO.

B. E. Sunny, General Electric Company.
C. H. Wilmerding, Chicago Edison Company.
M. A. Sullivan, Charles A. Schieren & Company.
W. H. McKinlock, Metropolitan Electric Company.
C. E. Gregory, Charles E. Gregory Company.
J. B. Wallace, Wallace Electric Company.
William S. Hine, Wallace Electric Company.
S. F. B. Morse, S. F. B. Morse & Company.
George S. Searing, Hart & Hegeman Mfg. Company.
F. S. Terry, Sunbeam Lamp Mfg. Company.
Charles G. Burton, Central Electric Company.
J. C. Shainwald, Standard Paint Company.
R. J. Randolph, Excelsior Electric Company.
M. B. Austin, Safety Wire and Cable Company.
E. H. Fox, Phœnix Glass Company.
Carl K. McFadden, Nutting Electric Company.
George Cutter.
H. H. Cutler, Cutler-Hammer Mfg. Company.
H. H. Conover, J.A. Roebling's Sons' Company.
Prof. W. M. Stine, Armour Institute.
W. F. Collins, "Western Electrician."
F. L. Perry, "Western Electrician."
W. E. Kelly, "Western Electrician."
M. J. Sullivan, "Electrical World."
Mrs. M. J. Sullivan.
H. M. Angle, Chicago Cross-Arm Company
Carl Kammeyer, "Electrical Engineer."
E. L. Powers, "Electrical Industries."
E. Nashold, Nashold Cleat Company.
Charles F. Foster.
Thomas G. Grier, Bryant Electric Company.
M. M. Wood.
F. E. Donohoe, American Electrical Works.
Charles S. Marshall, Chicago Cross-Arm Company.
J. W. Wolff, New York Insulated Wire Company.
W. A. Remington, "Electrical Industries."
W. A. Hurd, Crane Elevator Company.
J. H. McGill, Peru Carbon Co.
Hugo Benedix.
W. B. McDonald, Calumet Gas Company.
H. F. Tate, National Conduit Mfg. Company.
Charles E. Wilson, Ft. Wayne Electric Corporation.

DETROIT.

At Toledo the Chicago delegation was joined by several Detroit gentlemen whose names follow:

W. H. Fitzgerald, Detroit Electric Light and Power Company.
George E. Fisher, Commercial Electric Company.
J.F. Cummings, Cummings & Engleman Conduit Company.
W. H. Yawkey, Cummings & Engelman Conduit Company.
J. E. Lockwood, Michigan Electric Company.
J. E. Livesey, General Electric Company.
A. Chase.

DES MOINES, IA.

J. A. Colby, Des Moines Illuminating Company.
Mrs. J. A. Colby.

PEORIA, ILL.

A. M. Searles, Diamond Electric Company.

ROCKFORD, ILL.

M. A. Beal, Forest City Electric Light and Power Company.

BOSTON.

C. L. Edgar, Edison Illuminating Company.

MILWAUKEE.

S. G. Coleman, Badger Illuminating Company.

NEW YORK.

C. B. Fairchild, "Street Railway Journal."

CEDAR RAPIDS, IA.

W. A. Green.

HOOPESTOWN, ILL.

W. M. Chase.

Storage of Energy Essential to Economy of Working in Central Stations.[*]

BY N. W. PERRY, E. M.

Mr. President and Gentlemen of the National Electric Light Association: The Committee on Data reporting at the Washington meeting stated that 1.5 pounds of coal per indicated horse-power with a combined engine and dynamo efficiency of eighty-one per cent would produce 402.84 watt hours per pound of coal. In the tabulated statement of data collected by this same committee the highest results of practice given were 208 watt hours per pound of coal. The next highest was 192, the lowest 25, and the average 91.7 watt hours, or only 22.7 per cent of that which the best practice under favorable conditions should give.

By far the larger number of stations reporting are small ones, in which the highest economies would not be expected, and we find as a matter of fact that most of these report results below the average. Discarding all results based on a consumption of less than 10,000 pounds of coal, we have an average for the largest stations of 127.7 watt hours per pound of coal. This is equivalent to a consumption of about five pounds of coal per indicated horse-power. The best results given (208) are equivalent to about three pounds per indicated horse power, or more than twice as much as the machinery involved requires for the best results. Bad as this showing is, it seems to compare favorably with foreign practice, for Professor Unwin[†] says: "Probably up to the present (1893), the consumption has in no case been less than 3.3 pounds per indicated horse-power."

When we consider how enormously short the results of actual practice in lighting stations are of those which are obtainable under the most favorable conditions with the same machinery, it behooves us to inquire into the cause of this deficiency and to see how far we can remedy it.

Professor Kennedy has made some very careful tests to indicate the effect of variable load upon coal consumption. Dividing the day into three portions, he determined the fuel consumption, the feed water evaporated and the indicated and electric horse-power developed during each period in an English lighting station. It will be seen that during the periods of light load the fuel consumption per horse-power is very large:

Coal Consumption in Boilers with Variable Load.

	11 A. M. to 6 P. M. 7 hours.	6 P. M. to Midnight 6 hours.	Midnight to 11 A. M. 11 hours.	Mean for 24 hours.
Total indicated horse-power hours	562	1,366	407	......
Total electric horse-power hours.	400	979	260	......
Coal per indicated horse-power hours pounds	6.88	3.26	6.26	4.65
Coal per electric horse-power hours pounds	9.67	4.55	9.80	6.62
Pounds water evaporated per pound coal.	5.92	9.60	9.27	8.21
Pounds water per indicated horse-power hour	40.7	31.3	57.7	38.3
Pounds water per electric horse-power hour	57.2	43.8	91.0	51.4

Comparing the consumption of steam and coal during mean load with that during the hours of heavy load (6 P. M. to midnight) we find that the mean steam consumption per electric horse-power hour was twenty-four per cent greater and the mean coal consumption per electric horse-power hour was forty-six per cent greater—the difference of twenty-two per cent being attributable to waste at boilers, due to irregular working. During the whole twenty-four hours the mean evaporation in pounds of water per pound of coal was only eighty-five per cent of the evaporation during the period of maximum load.

To show more clearly at what relative cost we produce power in our lighting stations with their variable loads and under other commercial conditions where the load is fairly constant, I quote Professor Unwin:

I. *Engines working on a very regular load, in conditions similar to those of an engine pumping to a reservoir.* Here for one effective horse-power exerted during 7,884 hours annually, engines of 1.47 indicated horse-power must be provided. Such engines may be taken to use fourteen pounds of steam per indicated horse-power hour in test trials, but in ordinary work seven and one-half per cent more must be allowed for leakage, working auxiliary engines and less careful attention; this makes the consumption fifteen pounds per indicated horse-power, or $15 \times 1{,}176\ (\frac{1}{.85})$ = eighteen pounds per effective horse-power hour. At nine pounds of steam per pound of coal, allowing also five per cent for lighting and banking fires, the engine would use 2.1 pounds of coal per effective horse-power hour.

Cost of Installation per Effective Horse-Power.

Cost of engines or with reserve 1.47 indicated horse-power= 1.47×$44.5	$65.42	
Cost of boilers=1.47×$24	35.28	
Cost of buildings=1.47×$30	44.10	
Total	$144 80	

Annual Cost of Working per Effective Horse-Power.

Interest on $144.80 at 4 per cent..	$5.79	
Maintenance and depreciation—		
Buildings at 2 per cent	.88	
Machinery at 7½ per cent	7.61	
Total fixed annual cost		14.28
Coal 2.1 pounds for 8,760 hours at $1.75 per ton	$16.10	
Petty stores	1.64	
Driving, stoking and cleaning	11.67	
		29.41
Total annual cost		$43.69

Steady Working Cost of One Electrical Horse-Power.

Cost of engines, 1.547 at $44.5	$68.84	
Cost of boilers, 1.547 at $24	37.13	
Cost of dynamo, 1 at $30	30.00	
Cost of buildings, 1.547 at $30	46.41	
	$182.38	
Interest on $182.38 at 4 per cent.	7.30	
Maintenance and depreciation—		
Buildings at 2 per cent	.93	
Machinery at 7½ per cent	10.20	
Total fixed annual cost		18.43
Cost of coal, 2.21 pounds, 8,760 hours, at $1.75 per ton	$16.94	
Cost of petty stores	1.64	
Cost of driving, stoking and cleaning	11.67	
		30.25
Total annual cost per electrical horse power		$48.68

II. *Engines working with variable load under conditions similar to those of an electric lighting station.* Here for one effective horse-power supplied on the average throughout the year engines of 5.87 indicated horse-power have to be provided. On account of the inefficiency and waste, due to variation of the load, it is best to estimate the steam and coal from experience in similar cases. Probably no electric lighting station at present works with quite so low a consumption as six pounds of coal per hour per electrical unit supplied. A consumption of nine pounds is probably much more common in the best managed stations. Six pounds of coal per electrical unit corresponds to 3.8 pounds per effective horse-power hour.

Cost of Installation.

Cost of engines for one average effective horse power with reserve, 5.87 indicated horse-power=5.87× $44.5	$261.22	
Cost of boilers=5.87× $24	140.88	
Cost of buildings=5.87× $30	176.10	
Total	$578.20	

Annual Cost of Working per Effective Horse-Power.

Interest on $578.20 at 4 per cent.	$23.13	
Maintenance and depreciation—		
Machinery at 7½ per cent	30.25	
Buildings at 2 per cent	3.50	
Total fixed annual cost		56 88
Cost of coal, 3.8 pounds for 8,760 hours at $1.75 per ton	$26.00	
Cost of petty stores	1.64	
Cost of driving, stoking and cleaning	11.67	
		39.91
Total annual cost		$96.19

In other words our power costs us 2.188 times as much in an electric light station as it should. If we figure out the relative costs per electrical horse-power the disparity will be still greater.

Using these same data, but carrying the results out to electrical horse-power, assuming a dynamo efficiency of ninety-five per cent., we have four pounds of coal per electrical horse-power.

Cost of Installation per Electrical Horse-Power.

Cost of engines, 6.17× $44.05	$274.56	
Cost of boilers, 6.17 × $24	148.08	
Cost of buildings, 6.17 × $30	185.10	
Cost of dynamos, 4, at $30	120.00	
Total	$727.74	
Interest on $727.74 at 4 per cent..	29.11	
Maintenance and depreciation—		
Machinery, $542.64, at 7½ per cent	40.70	
Buildings, $185.10, at 2 %	8.70	
Total fixed cost		78.51
Cost of coal, 4 pounds for 8,760 hours, at $1.75 per ton	$30.63	
Cost of petty stores	1.64	
Cost of driving, stoking and cleaning	12.00	
		44.27
Total annual cost electrical horse-power		$117.78

When we compare this with the cost resulting from steady working, viz., $48.68, we see what an effective method of storage means in our central stations. If our storage costs us nothing, it would result in a saving for each electrical horse-power generated per year of $117.78—$48.68= $69.10. But any system of storage which we may employ will involve expenditures, both in the way of losses in storage, which will have to be provided against by an increased plant to provide for the same ultimate output, and in the way of interest on the additional investment required by the storage plant. As a matter of fact, these additional costs must in all cases be less than the saving otherwise effected, else we are paying more for our economy than it amounts to. In the present case, our storage must cost us less than $69.10.

If we could take the variable load off between the boiler and engine, viz., devise some means by which the same amount of energy could be supplied by the continuous operation of a boiler plant working at its most economical rate, we would at once do away with one of the most serious losses due to irregular working. Let us see how much the saving would be if the irregular working of the boilers could be obviated without cost:

Cost of engines, 6.17 at $14.5	$247.56	
Cost of boilers, 1.547 at $24	37.13	
Cost of buildings, 4, at $30	120.00	
Cost of dynamos, 4, at $30	120.00	
Total	$551.69	
Interest on $551.69 at 4 per cent.	22.07	
Maintenance and depreciation—		
Machinery, $431.69, at 7½ per cent	32.38	
Buildings, $120, at 2 per cent..	2.40	
Total fixed annual cost		56.85
Cost of coal, 2.21 pounds for 8,760 hours, at $1.75 per ton	$16.93	
Cost of petty stores	1.64	
Cost of driving, stoking and cleaning	11.67	
		30.24
Total annual cost per electrical horse-power		$87.09

If we move our storage forward one step and introduce it between our engine and dynamo, so that everything previous to the dynamo would work continuously at its maximum economy, the account would stand thus:

Storage Between Engine and Dynamo. Cost of One Electrical Horse-Power.

Cost of engines, 1.547 at $44.5	$68.84	
Cost of boilers, 1.547 at $24	37.13	
Cost of dynamos, 4, at $30	120.00	
Cost of buildings, 4, at $30	120.00	
Total	$346.97	
Interest on $346.97 at 4 per cent..	$13.86	
Maintenance and depreciation—		
Machinery, $226.27, at 7½ per cent	17.02	
Buildings, $120, at 2 per cent...	2.40	
Total fixed annual cost		$33.28

---

[*] Read before the National Electric Light Association at its Eighteenth Convention, held at Cleveland, O., February 19, 20 and 21, 1895.

[†] On the Development and Transmission of Power, page 28.

Cost of coal, 2.21 pounds, 8,760 hours, at $1.75 per ton..........	$16.94	
Cost of petty stores....................	1.64	
Cost of driving, stoking and cleaning	11.67	
		30.25
Total annual cost per electrical horse-power.......		$63.53

Recapitulating, we have possible gains by introducing the storage by successive steps forward:

		Cost of Horse-Power at this stage.
Between boiler and engine......	$30.69	$48.68
Between engine and dynamo...	28.56	87.09
Between dynamo and distribution..................................	14.85	117.78
Total..............................	$69.10	

Battery Storage.

Supposing, in the case assumed, we endeavor to equalize the load by means of the storage battery. This will allow the boilers, engines and dynamos to work continuously at their most economical rate and would seem to provide ideal conditions of working. We are not, however, storing the product we have to sell as is the gas manufacturer—we are not storing electrical energy, as some suppose, but chemical energy, which must be transformed again into electrical energy before we can distribute it. These two transformations, of course, involve a loss of energy which must be provided for in boilers, engines and dynamos, and also in coal. To be entirely fair with the storage battery, let us assume that its efficiency under all conditions is seventy-five per cent. Then in order that we may have at average working one electrical horse-power, we must provide:

Boilers,	$\frac{1.547}{.75}$ = 2.07 at $24.........	$49.68
Engines,	$\frac{1.547}{.75}$ = 2.07 at $44.5..	92.12
Dynamos,	$\frac{1}{.75}$ = 1.333 at $30.........	40.00
Buildings, say.........	....	125.00
Total investment, without storage battery..........		$306.80

If we are to produce an average of one electrical horse-power per hour, we will produce twenty four horse-power hours during the twenty-four hours, half of which must be stored, viz., we must have storage battery capacity for twelve horse-power hours. Of course, the rate of discharge will have some bearing upon the cost of this storage battery capacity, but taking an abstract case, we may assume, I think, without being unfair, that it will cost $35 per electrical horse-power hour capacity erected. We must, therefore, add to our former figures 12× $35=$420, which is more for the batteries than we have allowed for all the rest of the plant put together, including the buildings.

The total fixed investment therefore becomes............$726.80		
Interest on $726.80 at 4 per cent.	29.07	
Maintenance and depreciation—		
Buildings, $125 at 2 per cent...	2.50	
Machinery, $181.80 at 7½ %.......	13.64	
Storage battery, $420 at 10 %...	42.00	
Total fixed annual cost......		87.21
Coal 2.95 pounds for 8,760 hours, at $1.75 per ton.....................	$22.61	
Petty stores, attendance, etc.......	13.31	
		35.92
Total annual cost per electrical horse-power.......		$123.13

which would be an actual loss over that of irregular working of $123.13—117.78=$5.35. It will cost with the storage battery thus used, $123.13—$48.68=$74.45 more than the same machinery working continuously on a steady load could produce it for.

If we assume coal to cost $3.50 instead of $1.75, the cost per electrical horse-power will be:

Steady load without storage battery..........	$52.31
Variable load without storage battery......................................	148.40
With storage battery..................	145.74

We thus see that the storage battery on account of its high price costs more than it saves where fuel is cheap, but shows an economy as the price of fuel advances until with coal at $3.50 the economy becomes $2.66. This does not condemn its use in central stations in other ways, however, for there are many cases in which its use may contribute to economy, but these cases cannot be determined by any general rational formula. Each case must be determined for itself, and the result will depend primarily upon the shape of the load line, and secondly, upon the ability of the battery to rise above normal discharge rate economically. In the case of a station previously equipped, without storage, so that the units are already determined, the question of economy of introducing storage batteries will be determined in some cases entirely by the sizes of those units.

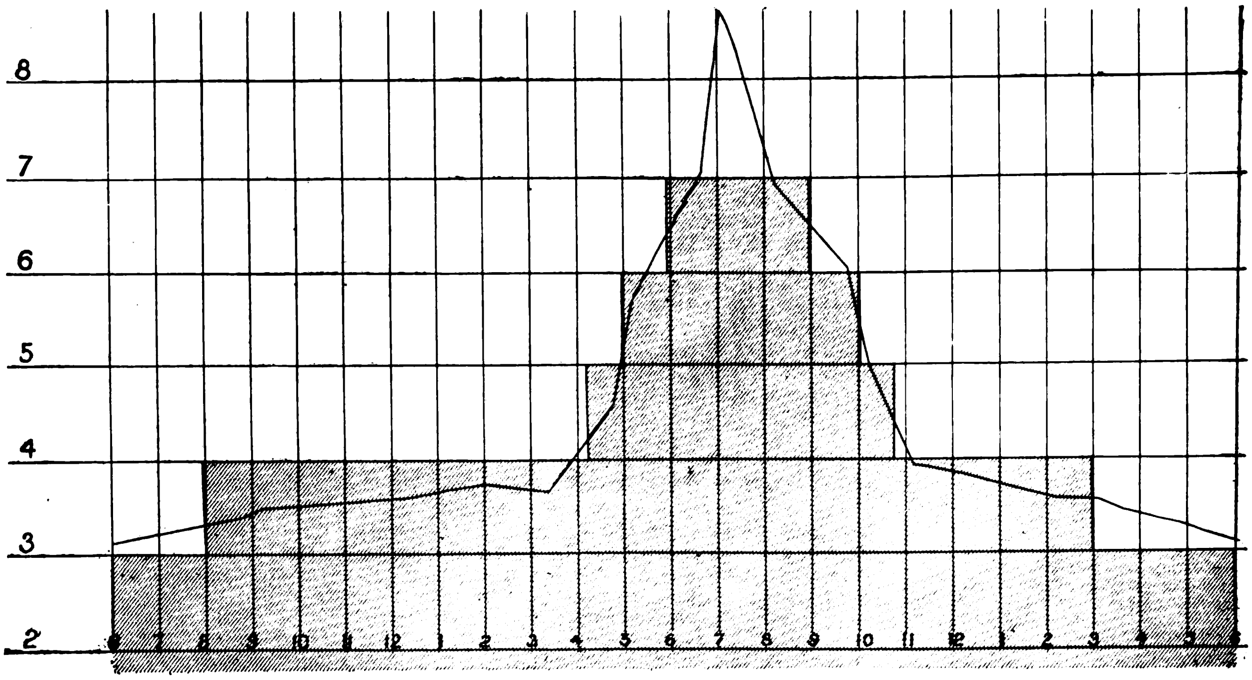
In some cases where the day load is exceedingly light it will not warrant the operation of the plant at all—the load costs more than it will bring in. In such cases there can be no question as to the economy of the storage battery, since it can be charged during the night by power that would otherwise be practically wasted, and during the daylight hours it may carry the whole load. In such cases it will effect an economy in another way also, viz., by carrying up to its capacity the peak of the load. The economy in this direction will be the greater the sharper the peak and will disappear as this flattens out.

But the manner in which the storage battery is most frequently employed to advantage in a central station is by changing the load line from the irregular one, due to the natural load, to one which would be formed by a series of rectangles which would in the aggregate have about the same area.

I have endeavored to illustrate this in the accompanying diagram. The irregular black line represents the natural load line. The spaces between the horizontal lines represent the units into which the equipment is divided, and the vertical lines the time at intervals of two hours.

Beginning at 6 A. M. the load is a little above the best output for three units, but without too much overloading these three units can carry it. The line gradually rises, however, until at 8 A.M. it becomes too much of an overload for three units. If a fourth unit were thrown in it would at first have to operate at only about one-third load, and hence very uneconomically. A storage battery load sufficient to make up a full load for this unit would, therefore, be thrown in at 8 A.M., and the new unit would thus work economically from the start. The part of the load furnished by the battery is represented by the shaded portion outside the natural load line—that is to say, this much energy is being absorbed by the battery and will be available at another time—less the loss due to inefficiency of the battery. I have assumed a battery efficiency of seventy-five per cent. We see from the diagram that the battery is charged 8 A. M. to about 4 P. M. Twenty-five per cent of the energy *thus* stored will therefore be lost. It will be apparent that this bears no relation whatever to the total amount of energy being generated at the time, for units 1, 2 and 3 are working directly into the feeders and are not affected at all. The energy thus lost bears an exceedingly small ratio to the total energy generated.

At 4 P. M. the natural load consumes all the energy of the third unit, and in about twelve minutes has increased so as to be an overload.



ADJUSTING BATTERY STORAGE TO ELECTRIC LIGHT LOAD.

Now it depends upon circumstances whether we will bring our stored energy to the assistance of the fourth unit to carry the increasing load further or not. For the purpose of illustration I have assumed that we will not, but will throw in our fifth unit and complete its load by charging the battery. At ten minutes to 5 the load crosses the fifth unit line, rising very rapidly, and the same question arises again, but I throw in my sixth unit at once, completing its load; the shaded area outside the natural load line again being the energy taken by the battery, seventy-five per cent of which will be available. At 5.30 the load exceeds the normal capacity of all six units, but the diagram represents them as carrying the increasing load until 6 P. M., when the seventh unit is thrown in, and the load completed by the storage battery until 6.40, when the natural load requires the whole attention of all seven units.

Now the question arises, will it be necessary to add first an eighth and then a ninth unit to take this peak? If so, it will add considerably to the fixed charges on our power account. Will it be cheaper to supply battery capacity to carry this peak? That is a question to be decided separately for each individual case. Storage batteries will stand an abnormal discharge for a short time without serious injury. Some will stand it better than others. If it be too rapid the depreciation charge will be increased, also if this abnormal discharge be continued too long. Then, too, at rapid discharge the battery becomes less efficient and the loss will become greater than twenty-five per cent. It is only by balancing these losses against the advantages that the question can be decided whether it will be more advantageous to throw in an eighth unit and let the battery take care of only the tip of the peak beyond that, or let the battery take the whole of the peak beyond the seventh unit line. In the diagram I have assumed that the latter is more advantageous. The battery, therefore, discharges until 8.20, when it begins to recharge, supplementing the seventh unit load until 9 P. M., when the seventh unit is thrown out entirely, and the battery carries the remaining seventh unit load until 9.25, the battery load being represented by the unshaded triangle within the load line. And so the battery and units continue supplementing each other throughout the remaining hours.

In this way the battery will prove economical with some curves. In others it may not, but whether or not it will depends upon so many contingencies that it is utterly impossible to state *á priori*. There are other considerations than economy that might balance its absence, such as convenience as a regulator of potential; the facility it affords for distribution to sub-stations at high potential, resulting in an economy of copper; and the subsequent transformation down for local distribution; and some others which will suggest themselves. Some of these might be controlling in special cases.

Then, on the other hand, the employment of the storage battery is limited entirely to the storage of energy when generated in the form of electricity; not only this, but it is still further limited to direct currents, and is therefore of no avail in stations sending out alternating currents.

(*To be continued.*)

London Notes.

(From our London Correspondent.)

ELECTRIC CURRENTS AND THE HUMAN BODY.

One of the highest medical authorities in England has just made a splendid attack upon the medical electrician in a lecture delivered by him on February 11th before the London Institution. Taking as his subject "Truth and Falsehood as to the Effect of Electric Currents on the Body," he showed the present state of our knowledge regarding the subject. Referring to the effects of the various currents on nerves, he showed a number of experiments and quoted Galvani's celebrated frog experiment. Some of our "quacks" advertise their electric belts and such wares in the stereotyped phrase "Electricity is the Life," and Prof. Horsley showed the falsehood and deceit therein contained. The only legitimate purpose for which an electrical current could be used in medicine or surgery was to stimulate or call out action in some particular muscle, or to stimulate some other physiological action such as secretion. But the currents required to do this must be powerful and intense. After speaking in very strong terms of C. B. Harness's Company and its quackery, he referred to electrical quackery having had to be slaughtered by public-spirited private individuals instead of by the public prosecutor, whose real duty it was.

ELECTRIC LIGHT WORKS BURNED DOWN.

On Tuesday, February 12, the electric light station of the Kensington and Knightsbridge Electric Lighting Company was burned down. Fortunately the engines and other plant escaped with very little injury, and under the able management of the engineer in chief (Mr. R. E. B. Crompton) a constant supply was maintained throughout the night.

ELECTRIC MOTIVE POWER IN MINING.

Before the Midland branch of the National Association of Colliery Managers on the 9th inst. Mr. Albion T. Snell, M. I. E. E. and A. M. I. C. E., delivered a lecture on this subject. He said that the large success attained by electric plants in collieries was due as much to their simplicity as to their efficiency. Hitherto in this country mining plants have always been worked by a continuous current system. The alternate current systems have not been applied owing to various reasons. The simplest way of transmitting power was by two series wound machines as used in the large pumping and hauling plant at St. John's Colliery, Normanton, and at many other pits. The necessary conditions for transmitting power were that both machines must be designed for the same maximum current, the dynamo must be run at constant speed, and the characteristic curves of the two machines must be such that the differences in pressure between the total electromotive force of the dynamo and the counter electromotive force of the motor and the working part of the curves must be equal to the pressure lost over the resistance of the entire circuit. It is not easy to fulfil these conditions in practice, but a sufficiently near approximation is obtainable without difficulty. The simplicity of this arrangement had done much to commend the use of electric power. This system, however, was not suitable for the supply of a number of motors, and therefore the parallel system in one of its forms had to be adopted, because in order to run motors in series the high pressure is required, and governors are necessary to control the speed of each motor. The parallel systems suitable for power work are: simple parallel or tree systems; feeder systems with two wire distributors; three-wire systems; three-wire feeder systems, and dynamotor sub-station systems. The simple parallel system was not suitable for a plant in which the power is taken off at a number of points relatively far apart, as in a coal-pit. The feeder system was that upon which most of the underground plants are laid when a compound dynamo is employed. Each district is supplied by a separate pair of mains joined to the omnibus bars at the shaft bottom, and lamps and motors are coupled in parallel. The weak point with the feeder system is the fall of pressure between the distributing point at the pit bottom and the motors when they are a long way in-bye, and hence a difficulty of regulating the speed of each motor independently of the others, although the pressure at the end of the feeders might be kept fairly constant. The lecturer had never heard of a satisfactory plant even in a colliery in which the line loss at full load exceeded about 30 per cent.; but there are many in which it is from 25 to 30 per cent. which would probably correspond to a 15 per cent loss at average load. Regarding the alternate current systems experts agreed that these would ultimately supersede the continuous current ones, at any rate for long distance transmission, and he himself thought they would be likely to play an important part in the working of mines during the next decade. He next explained the difference between an alternate current and a continuous current system, and after further lengthy remarks regarding the selection of plant for mines and some comments regarding shaft cables, underground cables, bare returns, safety cables and motors, and mechanical coal-getting, Mr. Snell concluded a very interesting lecture by describing some electrical coal cutters.

American Institute of Electrical Engineers.

The 94th meeting of the Institute will be held at 12 West 31st street, New York City, on Wednesday, February 27, at 8 P. M.

A paper will be presented by Mr. H. Ward Leonard, of New York City, entitled "Notes on Recent Electrical Engineering Developments in France and England." Among the topics treated will be Rotary Transformers, the Parsons Steam Turbine, the Laval Steam Turbine, English and French Central Stations, the Heilmann Locomotive, etc.

A meeting of Western members will be held the same evening, Wednesday, February 27th.

The Commercial Side.

Hustlers for Business at the Cleveland Convention.

Mr. R. B. Corey arrived a little late, but was as eloquent as ever in discussing the merits of the latest types of arc lamps for all circuits.

The interests of the Wallace Electric Company were thoroughly cared for by Mr. John B. Wallace and Mr. William Hine, who also chanted the praises of the S. K. C. system of transmission.

In the absence of Mr. L. F. Requa, M. B. Austin, of Chicago, was a capable representative of Safety Insulated Wires and Cables.

Mr. J. Holt Gates, of Chicago, looked out for the credit of the Mather Company and the other companies which he has represented so successfully in the West.

Morse, of Chicago, S. F. B. of course, had the old but true story to tell of the staying qualities of Day's Kerite.

The American Electrical Manufacturing Company of St. Louis were well and capably represented by Mr. Louis Nahm, secretary, and his assistants, Messrs. Gerleman and McConnell.

Mr. Hugo Benedix in politest manner introduced to the fraternity the Boudreaux Dynamo Brush.

Among the larger representatives who were not so far very well known at the Light Conventions was Mr. S. Bowman Wheeler, of Morris, Tasker & Company, Philadelphia. He will be remembered for certain next time.

Among the attractive exhibits that of the Sweet Electric and Manufacturing Company of Grand Rapids was entitled to special mention.

Mr. E. G. Bernard, of Troy, was industrious and successful in booming the well known Powers Arc Light Cut-Out and the newer Adams Dynamo and Motor.

The Clonbrock Steam Boiler Company's exhibit was in the new station of the Cleveland Lighting Company and made them many new friends.

Mr. R. J. Randolph, of Chicago, was in sight again after missing one or two Conventions, and his Excelsior story was as loud and strong as ever.

In their large parlor at the Hollenden the American Circular Loom Company of Boston had one of the most striking exhibits of the Convention.

The Eureka Compound Company of Sioux Falls, S. D., gave out samples of their material which resembled a small stick of candy in size but not in aroma.

Mr. Charles F. Munder was on deck in the interests of the Bryan Marsh Company and their incandescent lamps.

Mr. C. I. Hills of the New York office was the man who guarded the good reputation of the Columbia Incandescent Lamp Company, being fully equal to the occasion.

Messrs. Stettinius and Faber allowed no interested party to remain in ignorance of the special merits of the Stirling Water Tube Boiler, and literature was abundant showing the great popularity of that type of boiler.

Mr. Elmer P. Morris, who has as many friends in the trade as in the old days, introduced the Phœnix Rubber Insulating Paint, and had at all times an appreciative audience of central station men and others who have for a long time felt the need of an article such as Phœnix Paint promises to be.

Messrs. James W. Godfrey and Frank Harrington, who were in sight for twenty-four hours a day during the entire meeting, were never weary of telling their story of the strong points of Habishaw Wire, which has had a new boom since their connection with the company.

The most elaborate display of the entire meeting, and one well worth looking at, was that of the Buckeye Lamps. Messrs. Rockwell, Potter, and assistants were constant in attendance, and in addition to getting a splendid advertisement took several handsome orders.

The American Electrical Works had no exhibit, but Mr. P. C. Ackerman, their representative, landed easily a very good order between handshakes with his friends. Mr. F. E. Donohoe of the Chicago office was also in attendance.

Messrs. Charles D. Shain and R. O. Heinrichs gave a good imitation of the spider in the old poem. Their parlor was the scene of many quiet conferences at which several thousand dollars' worth of Weston instruments were sold to men who needed them—as all central station men do.

Mr. James F. Kelly, who is one of the old-time Convention delegates, was very much in evidence as the representative of the New York Insulated Wire Company.

Dr. G. A. Gessner and Mr. Edmund Dickey were constant in attendance, and it goes without saying that the American Carbon Company were well represented.

Micanite and the Mica Insulator Company were well taken care of by the Cleveland agents, the Cuyahoga Supply Company.

The Wagner Electric Manufacturing Company of St. Louis, through Mr. Herbert Wagner, president of the company, were prominent among the exhibitors with their well known transformers, motors, switches, regulators, switchboards, etc., etc.

The Packard Lamps and Transformers occupied a conspicuous space in the exhibit hall, the main feature being their Great Mogul lamps and a novel arrangement for showing a transformer in which the heat was dissipated by water circulation.

Messrs. Crouse and Tremaine of the Fostoria Carbon Works were both on hand full of fighting blood and the courage of their convictions on their product.

Mr. S. Marsh Young and his partner were kept busy with the display of the Manhattan General Construction Company. The new 100-hour lamp, on which one pair of ½ inch carbons do the work of eight pairs in the standard lamps, attracted wide attention.

One of the newer arc lamp companies represented was the Imperial of New York, with a good lamp and a good hustler.

Mr. Charles Rodman, of the Globe Carbon Works, without whom no Convention could be successful, was on hand and in good spirits.

George Cutter, of Chicago, was as earnest as ever in his efforts to push his specialties—street-hoods, pulleys, windlasses, etc.

Mr. F. Houghton, who is the regular Cleveland representative of the C. and C. Electric Company, was constant in attendance, with a good record to show for himself, his company and their machines.

Mr. F. L. Babcock had not far to come, but he would have been there if it had been a journey of 1,000 miles to let the people know that the Falls Rivet and Machine Company is still as lively as ever.

Frank R. Colvin, no longer the associate of advertising men, but now their victim, aroused considerable fresh interest in the Interior Telephone, with which 300 buildings have already been equipped.

The Stanley Company of Pittsfield were very much in evidence through Messrs. Henry Hine and John F. Kelly, who had little trouble in holding up their end of the tri-cornered contest for supremacy in transmission apparatus.

Mr. George H. McKinlock, of the Central Electric Co., was there in a dual capacity as representative of his own company and of the Okonite Co., whose special agents the Central Co. are in the West.

With Mr. McKinlock, Capt. Candee, and George Manson the Okonite trademark was as prominent in the lobby as it was in the crazy-quilt imitation in the newspapers—always in preferred position.

The Metropolitan Electric Company of Chicago was represented by its president, Mr. W. H. McKinlock, who holds with some reason that the large line of supplies carried by the firm are so well known that no large exhibit was necessary.

Messrs. Seely and Belden of the Complete Electric Construction Co. were on hand to take any construction contract in sight if the terms were right, and to put up bonds in any amount to guarantee a good job.

H. T. Paiste, of Philadelphia, was as popular as ever with his Xentric switch.

The Partridge Carbon Co. of Sandusky, makers of high-class motor brushes, were represented by Mr. Partridge, who was one of the early Brush men and formerly lived in Cleveland.

McIntyre, of Newark, C. H., had a true and interesting tale to tell of the merits of his line of terminals, connectors, etc., which have secured for them a large sale.

The Multifuse Switch Company of Cleveland, exploiting a new and desirable switch, had no trouble in convincing many central station men that the Multifuse is a good thing.

The Holtzer-Cabot Electric Company of Boston had a creditable representation showing their standard types of Fan Motors, alternating and direct, and displayed a handsome line of literature.

The Beacon Lamp Company of Boston was represented by Mr. J. D. Hambey.

The Bryant Electric Company's interests were carefully looked after by Mr. W. C. Bryant and Mr. Thos. Grier, the company's Western agent. A choice bit of their literature was a little pamphlet containing good stories—and descriptions of Bryant specialties.

The Helios Lamp Company of Philadelphia had an instructive exhibit showing the peculiar merits of the Helios Lamp. The lamps were focussed upon a screen in a manner to prove the perfection of feed arrangements and the satisfactory conduct of the lamps. Mr. Frank S. Marr, the president, was in charge.

The Diamond Electric Company made an attractive exhibit embracing the Scheeffer wattmeter and the Diamond transformer. This exhibit was in charge of Mr. A. M. Searles, one of the old-timers in the business, who was welcomed by many friends.

The Electric Storage Battery Company of Philadelphia showed the highest development in this branch of the art in their well known Chloride cell. Mr. Herbert Lloyd was present part of the time, but was called away on important business.

Mr. James S. Humbird made his first Convention appearance for several years, looking just the same as he did eight years ago when he was one of the leading salesmen of electrical apparatus. He was ably assisted by Mr. J. S. Crider, and the new cored carbon of the Washington Carbon Company—the Helios—was well advertised. The central station men were much interested, as the orders in Mr. Crider's pocket showed.

The National Carbon Company was represented by Messrs. B. F. Miles and George Hackenburg, who both appeared serene and content.

Mr. W. B. Cleveland had an interesting exhibit of Roll-Drop Commutator Bars from the Forest City Electric Works, of which he is at the head. The remarkable feature of these bars is that they are sold mystery-off, no lost art being needed in their production.

Mr. E. W. Little of the Interior Conduit Company, assisted by Mr. Kittel and Romaine Mace, had no trouble in taking several good orders and in representing his company properly. Their parlors were a recognized headquarters and were always open.

Mr. Henry B. Cutter of Philadelphia was, as usual, on hand with the full line of C. S. Special ties, which have been a feature of the exhibits at every recent Convention.

The Electric Selector and Signal Company was ably represented by Messrs. C. P. Mackie and P. H. Alexander, both of them old-timers and up to date in showing the merits of a good thing.

The Shultz Belting Company of St. Louis were represented by their Cleveland agents, Messrs. Parkin & Bosworth.

Mr. J. J. Gates was hustling in old-style manner in the interests of the Perkins Switch Company of Hartford, and had an attractive display to assist him in proving the truth of his story.

Mr. Jos. E. Lockwood of the Michigan Electric Company was on deck with a Detroit dynamo, and also recounting the merits of the choice line of specialties for which his company has the Michigan agency.

Mr. J. P. McQuaid of the National Conduit Company was well assisted by Messrs. Gallaher of New York and H. T. Tate of the Chicago office.

The Western Electric Company sent as representatives Messrs. S. A. Chase of New York and Wilkinson of Chicago.

The Abendroth & Root Boiler was boomed by Mr. P. H. McLaren, who knows as much about boilers as any man in the country and never wearies of telling his story. Moreover, he commands attention.

Mr. G. W. Hart, who has been familiar with the progress of the art since 1880, presented the well known Hart & Hegeman line of switches, assisted by Mr. George S. Searing of Chicago.

The Fort Wayne Electric Corporation had, as is customary, handsome entertainment quarters and the liveliest corps of hustlers in sight. Charles S. Knight got in a little late but made up for lost time. The others were: G. A. Miller Philadelphia; S. A. Douglass, New York; T. J. Ryan, Cincinnati; Tom Cooper, Columbus, O.; C. E. Wilson, Chicago, and Mr. Wilbur of Philadelphia.

Mr. F. S. Terry of the Sunbeam Lamp Company was on hand because he could not stay away, and incidentally to serve notice that in a few weeks he would be very much in sight again.

The G. E. Company had a large delegation, eighteen in all, including S. D. Greene, Professors Thomson and Steinmetz, and Messrs. Paige and Howells of the Lamp Works.

The headquarters of the Westinghouse Company were in front—as the company itself usually is. The delegation included: C. A. Bragg, C. Townley, Chas. F. Scott, F. S. Smith, J. A. Rutherford, R. D. Mershon, B. Lamme, H. P. Davis, A. J. Wurts, H. D. Shute, E. H. Heinrichs, M. Crompton, Jas. C. Hubner, Geo. B. Dusinberre, E. N. Sanderson, H. L. Craigin, J. S. Tebbetts, P. T. Brady, George H. Lewars, and Mr. Terry of the legal department.

The Brush Company and the Swan Lamp Company were in the large parlor on the first floor with an exceptionally attractive exhibit, Col. L. H. Rogers commanded.

Prof. Sidney H. Short of the Walker Manufacturing Company, with assistants, entertained quite a party of tourists by taking them in carriages for an inspection of the large works of the company on the West Side.

The Standard Underground Cable Company was represented by J. W. Marsh, vice-president; G. L. Wiley, Eastern manager; J. R. Wiley, Western manager, and H. W. Fisher, electrician—who were fully able to protect the reputation of Standard Underground.

A basement exhibit which attracted well-deserved attention was that of the improved Leonard heater. H. Ward himself was in charge; adjoining was the exhibit of the Carpenter rheostats guarded by Mr. C. E. Carpenter.

The Electric Engineering and Supply Company of Syracuse were on hand with a handsome exhibit and a new catalogue describing the many old specialties of the company and several new ones. They were ably represented by Messrs. J. D. McIntyre, J. L. Hinds and H. C. Hodgkins.

The Libbey Glass Company of Toledo were well represented by Mr. S. C. Richardson, who was busy looking after lamp men.

Among the other concerns represented by good hustlers were: The Chicago Cross-Arm Company; the Chas. E. Gregory Company, Chicago; Triumph Electric Company of Cincinnati; Nutting Arc Lamp Company, M. M. Wood; Chicago Rawhide Company; Cutler & Hammer, Chicago; Henry R. Worthington, New York; Rouse & Hills; Elliott Lincoln Electric Company, Cleveland; Akron Insulator and Marble Company, Akron; Solar Arc Lamp Company; McCreary Specialty Company; Rossiter & McGovern, New York; Anchor Electric Company, Boston; Phœnix Iron Works, Meadville; Cleveland Electrical Manufacturing Company, Reliance Gauge Company, Tucker Electrical Construction Company, Standard Paint Company, Munson Belting Company, John A. Roebling's Sons, Penn Electric Manufacturing Company, Canton Glass Company, Aylsworth & Jackson, Pass & Seymour, Brooklyn Electric Manufacturing Company.

Professor George Forbes says of the Niagara Falls power transmission scheme: "It is difficult for me to say who are the bolder, the capitalists who are embarking into the scheme or the manufacturers who are moving their factories before a single result has been achieved. The action of both is typical American, and their confidence was not misplaced, as the success of the scheme is now assured."

Electric conduits made of small, vitrified stoneware sewer pipe laid in concrete on brick subways have been introduced in England. The conductors employed are naked copper strips which rest on insulators, the pipes themselves, each two feet long, resting on porcelain bridges. In order to join the conductor with a house connection, a special length of pipe is furnished, which is U-shaped for a part of its length. The house lead is taken out through an insulated removable cover forming the top of this part of the pipe. The joints are made on the Doulton system, and require no cement.

The Monocyclic System.*

BY DR. LOUIS BELL.

To the Central Station man no recent change in engineering practice can have more interest than the renaissance of alternating current work which is now in progress. Truth to tell, until quite recently the alternating current was somewhat under a cloud in the estimation of both station managers and engineers. It has served an immensely useful purpose in the extension of electric lighting to places where it would have been utterly impracticable to install a direct current system of any sort, on account of the scattered nature of the work. A very large number of stations have been installed on the alternating system, and I am sorry to say that a large proportion of them have been somewhat unsatisfactory, not in their general operation, but in the character of their service and the commercial results. It is quite common to find alternating stations with a plant efficiency considerably below 50 per cent., and in which the regulation is maintained only within, perhaps, about ten per cent. Under these circumstances, it is small wonder that the advocates of the direct current, the uses of which as an engineering problem have been very completely worked out, have been often somewhat violent in their animadversions on alternating currents in general. Nevertheless, in the last two or three years, there has been a vast change for the better in alternating practice : a change not yet rapid, but bidding fair to be far-reaching. This change has taken up a three-fold path towards progress :

First, the use of large transformers is becoming more frequent.

Next, these transformers are more and more used in conjunction with systems of secondary mains ; and, finally, it is now possible to install an alternating plant that shall be able to operate motors as successfully as can be done with direct current. In ordinary central station practice the motor service does not usually play a very important part : nevertheless, the ability to run motors is most valuable. It is more profitable, speaking broadly, to sell current for light, for a better price per kilowatt hour can be obtained ; at the same time, if motors can be readily furnished, a useful day load can be obtained when it is needed, and the plant becomes the greater service to the community, a thing which, in these days of more or less friction with common councils, is of no small importance. Not only can motors now be successfully worked off alternating circuits, but off a wide variety of such circuits. As yet, however, there is no successful motor for use on the simple alternating system which has, for the most part, been installed in this country. While it is possible to construct a single-phase motor even for 120 or 130 cycles per second, the frequency most used in America, it is at present very doubtful whether such a motor can be made to start and run in a way which will be generally satisfactory. Abroad, where low periodicities are used, better results can be obtained, but even there, there is a noticeable silence on several important points in describing alternating motor practice. Appearances indicate that even with the advantage of low frequency, motors for use on simple alternating circuits still start badly, and particularly require enormous currents at the moment of starting ; hence the growth of various modified alternating systems, of which the polyphase are the best known, by the use of which it becomes possible to avoid this difficulty entirely and to work alternating current motors in every respect as satisfactorily as those operated by direct current.

The polyphase motor has solved the problem of securing good motor service with alternating currents in a very complete manner, although at the cost of slight complications, which, while generally overestimated, are nevertheless distasteful to central station men, especially where the use of such a system would involve an extensive and costly re-arrangement of the distribution service. It is the purpose of this paper to call your attention to the various methods of central station distribution, involving motor service on the alternating current system, and more especially to a modified single-phase alternating system, which lends itself very readily to a very simple and straightforward distribution for lighting without sacrificing the excellent motor service, which makes the true polyphase system so desirable. For all around central station work, the lighting service is of most fundamental importance, and convenience and economy in this particular must, in a vast majority of cases, be the first consideration. Let me invite your attention to this chart, which shows in a diagrammatic manner the general arrangement of various alternating circuits, including those already familiar and the polyphase and monocyclic systems.

First in order, both of time and extended use, comes the simple alternating system, single-phase, with an ordinary two-wire distributing circuit. In operating the secondaries of such a system, we run immediately into limitations imposed by the feasible voltage for lamps, limitations which have acted as a brake on alternating current work, and which are responsible for a good many difficulties in the operation of alternating plants. Opposite the diagram of this circuit I have placed the relative amount of copper required for lighting with such a distribution.

Next comes the alternating circuit modified for Edison three-wire distribution, which is so familiar in its character that it needs no description here. The amount of copper needed, on the supposition that neutral is half the size of either of the others, is, of course, enormously reduced, amounting, as you see, to less than one-third of that needed with the two-wire system; consequently the secondary main distribution, so important to economical operation, can be carried out with the greatest facility. We are justified, at present, in saying that neither of these systems lends itself to the ready operation of motors.

We may next consider the two-phase alternating system, worked with four wires, giving, if desired, two separate circuits for each machine. The copper here required is the same as that used with the single-phase, and so long as the four wires are kept together, motors can be freely operated. Here is assuredly a step in advance. The operation of two separate circuits, however, from a single machine, involves certain complications. In the first place, unless these circuits are balanced as to load, the operation of the system is somewhat difficult to make satisfactory in point of regulation. The circuits themselves have absolutely no influence on each other, but they are derived from the same machine, and with a given excitation of that machine, unless the loss in the two circuits is the same, the voltages must necessarily be different, consequently the generator cannot be compounded for both circuits unless the circuits are balanced. There are three ways out of this difficulty; none of them, unfortunately, is altogether unobjectionable.

In the first place, one can make the loss on the line so small that the difference in voltage, due to any reasonable difference in load, is of no moment. This can sometimes successfully be done, but more often it involves a very unnecessary cost for copper, and even at its best is likely to give regulation, which, although better than that found on most simple alternating systems, is yet not good enough to suit the requirements of the best modern engineering.

Second, the machine can be compounded for loss on one of the lines, a feeder regulator being used on the other. This practically means hand regulation of one circuit.

Or, finally, both circuits can be operated by such regulators. In any case, if motors are to be operated, the two phases must be interlinked at least by one wire.

A somewhat simpler two-phase distribution is that shown in the next diagram where the two phases unite into a common three-wire-circuit. The amount of copper here required differs very materially according to the limitations of voltage that one chooses to fix. If the maximum voltage of the system is limited to the same maximum voltage used on the single phase, two-wire or two-phase, four-wire system, the amount of copper required is very largely increased by the third wire, owing to the fact that the two circuits combined are out of place with each other by ninety degrees. The relative amount of copper required here is, as you see, 145.5. If, on the other hand, the question of maximum voltage between wires is neglected, and the voltage is determined by the use of lamps of the same voltages as on the other systems, then the amount of copper is materially reduced, being a trifle less than three-fourths of that required on the systems before mentioned. In this case, we neglect the fact of there being an excessive voltage between the two outside wires, and connect lamps between the middle wire and the two outside ones, much in the manner of an Edison three-wire system, with the exception, of course, that the saving in copper is not anything like the same amount. Such a system allows the distribution of the whole load for lights and power in a single circuit containing only three wires. It, therefore, avoids the difficulty of regulating two separate circuits. On the other hand, it causes a new and very curious difficulty, owing to the fact that the two combined phases are unsymmetrical with regard to the inductance of the system. The voltages between the middle wire and the two outside wires are unequal, when the systems are equally loaded, by an amount depending on the inductive loss on the line. Consequently, when in balance for regulation, the system is unbalanced as regards the load on the two sides; a condition which, although it may not lead to trouble in some cases, is still a menace to the successful operation of the system, unless the distribution be skillfully engineered. There is, however, the possibility of a noticeable saving in copper.

We may next pass to the three-phase alternating system. The system which corresponds to the two-phase, four-wire system, I pass by, as the use of three separate circuits would be even more troublesome than that of two, and would have no compensating advantages. The ordinary three-phase circuit is that shown in the figure wherein the three phases are united into three wires and taken everywhere the motors and lights are wanted. In this case, for the same voltage between wires, the amount of copper demanded is just three-fourths of that demanded for a single phase, two-wire or two-phase, four-wire circuit. To compensate for this, there is the possibility of unequal voltages in case the three legs of the circuit are unequally loaded owing to interaction in transformers and in the generator. So far as inductance on the line is concerned, the system is symmetrical and balanced.

If the load on three branches is very unequal, as, for example, if one branch is entirely unloaded or very lightly loaded, while the other two are worked to their full capacity, there will be a perceptible unbalancing of the voltage. Experience, however, shows that with anything like the same care in balancing that would apply to an Edison three-wire system, this theoretical difficulty of balance is absolutely negligible. I say this advisedly, as the question has been so often raised that I have taken pains to investigate the conditions in three plants operating lights with reference to this particular thing, and the statement just made is the result of actual practice, It might be thought at first sight that good results could be obtained by combining with either a two-phase or three-phase system the Edison three-wire distribution. As a matter of fact, such a system would be unreasonably complicated with either two or three phases, as any central station man will readily appreciate, inasmuch as it would be necessary to have two or three three-wire systems, each balanced, and mutually balanced with respect to each other, covering the territory if motors are to be run, or at least interlinked in a somewhat complicated way,

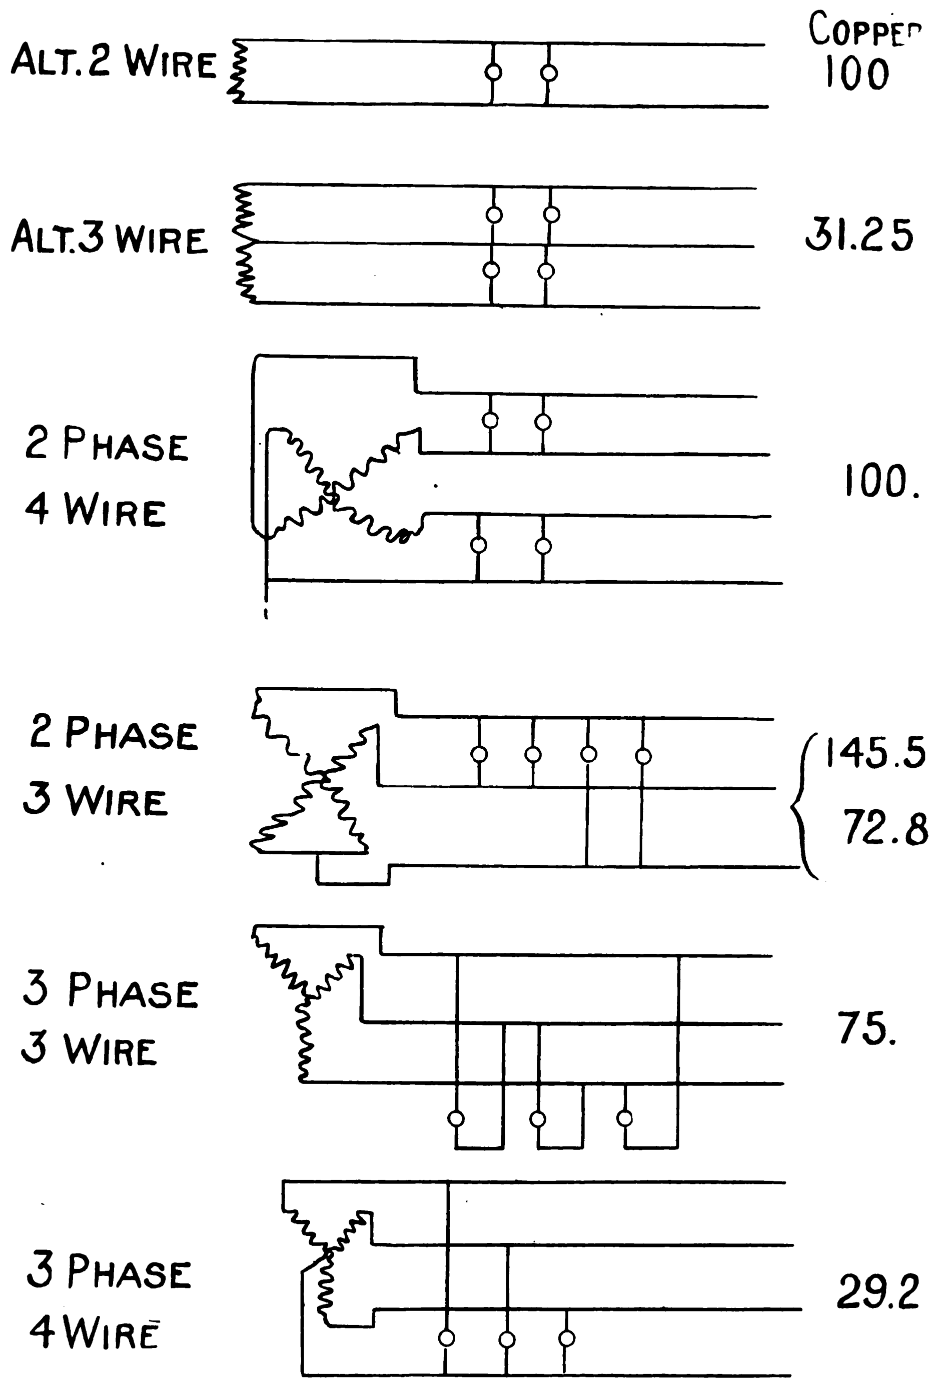
There is, however, a three-phase system which does secure a very great advantage in copper. This is the three-phase, four-wire system shown in the figure. It consists of the ordinary three wires employed on the three-phase system, with the addition of a balance wire proceeding from the common connection of the generator or the transformer and forming a part of the general distribution system. The lights are, as can be seen from the diagram, connected between either of the three-phase wires and the balance wire. Between each of the outside wires there are, therefore, what may be considered two lamps in series, having, however, a phase difference of 120 degrees. The voltage of transmission, then, between each of the three main wires, 1.73 times the voltage employed in the lamp connected, nearly 200 volts for 110 volt lamps. This necessarily means a large saving in copper, which is still further enhanced by the fact the three-phase, three-wire system requires intrinsically only 75 per cent. of the copper used on the single-phase or direct current system. The total result with this particular connection is but twenty-nine and one-half per cent. of the copper required on the single-phase system, supposing, as in the Edison three-wire distribution, the neutral wire to be half the size of either of the others. Such a system is in successful use at St. Hyacinth, Canada, in connection with long secondary mains. The price paid for this saving in copper is the introduction of a fourth wire into the distributing system.

Comparing, then, the lighting distributions on the two and three-phase system, we find that if three wires only are used, both have nearly the same amount of copper. The extreme voltage between wires on the two-phase circuit is, however, considerably greater, and both are liable, but not likely, to become unbalanced.

---

* Paper read before the National Electric Light Convention. Held Feb. 19, 20, 21, at Cleveland.

There is this difference, however, that if we are to balance a three-phase system in respect to voltage, we need only to see that the load is equally distributed between the three branches. If we are to balance a two-phase, three-wire system, we must see that this load is unequally distributed between the three branches by an amount depending on the inductance of the line. We, therefore, see, comparing the polyphase with the single-phase system, that the price we have to pay for the privilege of successfully operating motors is a certain amount of complication in circuits, which, while not of great importance in new installations, hinders the ready adaptation of a polyphase system in a plant having already a large number of circuits installed. Attractive as the single phase is in its beautiful simplicity of wiring, we cannot yet successfully run motors from it. It was for the purpose of preserving that simplicity of distribution which is peculiarly valuable in connection with large central stations, especially those already installed, and joining to this the same ability of running motors found on the polyphase system, that the monocyclic system, to which I am about to call your attention, has been perfected. You see it first in its two wire form. Here, so far as the lighting distribution is concerned, it is absolutely identical with any of the alternating systems now installed, in simplicity, convenience and in the amount of copper necessary. The main circuit of the monocyclic machine constitutes a simple single-phase alternator, and so far as the lighting on the system is concerned.is identical with it, connected in precisely the same way, feeding, if desirable, into the same circuits without change. There is, however, on the armature of the monocyclic machine a supplemental coil, shown on the diagram as connected to the middle point of the main winding on the monocyclic machine, from which a power wire may be led. This need be of but small cross section, and only has to be carried to those points in the system at which it is desired to operate motors, and, as I shall presently show, this power wire enables one to run motors possessing the same desireable. Characteristics as the polyphaes motors, and, indeed, generally identical with them, without in any way disturbing the lighting distribution, except in so far as Ohm's law is a necessary limitation on all combined power and lighting circuits. In the next diagram here we see the same device applied to an Edison three-wire system for the distribution of lights, along with which is carried the same insignificant power wire which permits the successful operation of motors. The value of the three-wire feature in the distribution of lights is evident, the amount of copper being the same as in an Edison system of the same voltage. With this monocyclic system, we can compound the generators for any reasonable loss in the line, and can arrange the lighting system without incurring any troublesome questions of balance, so far as to give as good regulation even as can be obtained on a direct current system. Beyond this, we have the power of running motors.



It is instructive to glance over this list of alternating lighting systems to see their relative complexity and advantages. It is especially noteworthy that any and every method of distribution that saves copper introduces in some form or other the question of balance. This is the price we pay for reduction in cost of conductors. It has not seriously interfered with the use of the Edison three-wire system; in fact, those most familiar with that system were the first to make light of the difficulty; nor do I think it stands as a valid objection to the use of the polyphase systems in cases where they are desirable, as none of them are more sensitive in the matter of balance than the Edison three-wire system which is now in such extensive and uniformly successful use. We may further note, that in each of the alternating systems where a very great saving of copper is accomplished, a fourth wire is necessary, at least if both lights and motors are to be operated; in each case, however, of trifling size.

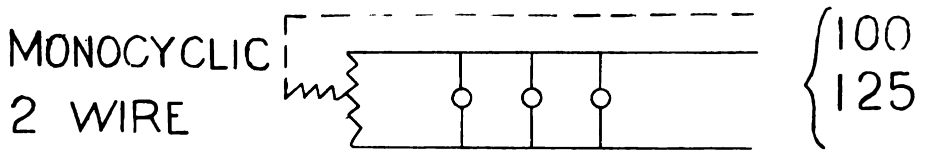
Having now looked over the field in general, we may pass to the more minute consideration of the somewhat striking electrical peculiarities of the monocyclic system; peculiarities which, although they do not involve any particular complexity, are yet of decided interest.

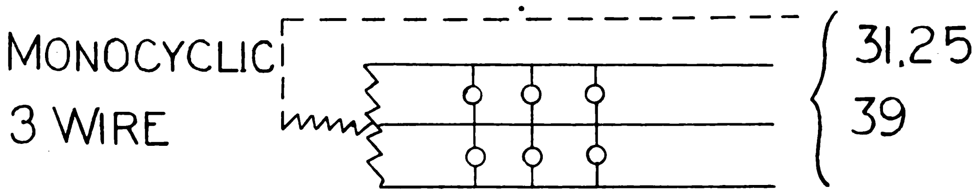
The general principle of the system is well shown in this diagram. So far as the main work of the generator is concerned, its winding is closely similar to that of any well-designed alternator. The armature is of the ironclad type, and the winding is made in machine wound coils which are invariably insulated, and can be very readily slipped into place. There is, however, upon the armature a second set of coils of cross section equivalent to that of the main coil, but composed of comparatively few turns, so that the room taken up on the armatnre is very small, and owing to the shallowness of the slots necessary to accommodate this second or teaser coil,' the output of the machine, considered as a single-phase generator, is not affected. This teaser coil is located with reference to the main coil as shown in the diagram. Its place on the armature is midway between the other coils, and the electromotive force generated is in a direction at right angles to that of the principal coil. It is evident, now, that if we connect the terminal of this teaser coil with either of the terminals of the main coil, we shall get an electromotive force compounded of the two, and in some intermediate direction. In general, by varying the proportions of the two coils, and hence their electromotive forces, we could obtain a resultant electromotive force between their terminals having any angle we pleased with either the main or the teaser coil. If, then, wires are taken upon the line from the terminals of the main coil, and also from the teaser coil, we can obtain from the main line three electromotive forces, two of which are symmetrically situated with reference to the E. M. F. of the teaser coil, and bear to it any phase relation that we please. One of the most convenient arrangements, and that which is most generally adopted, involves such a relation of the electromotive force of the teaser coil to that of the main coil, that we shall have on the line three electromotive forces approximately 60 degrees apart. In other words, the resultant E. M. F.'s between teasers and main coils are each 60 degrees from the E. M. F. of the teaser coil. Such an arrangement is that shown in the diagram. Under these circumstances, it is clear that if one of these electromotive forces were reversed, either in transformers or anywhere in the translating devices, the result would be three electromotive forces 120 degrees apart, one of them having been turned through an angle of 180 degrees. Meanwhile, the relation between the power wire, which is connected to the teaser coil, and the outside wire has no effect upon the electromotive force between these outside wires, since the electromotive force of the main coil itself does not interact with the power wire, except in so far as a portion of it may act with the power wire to form a resultant phase, and electromotive force for running motors. Consequently, so far as lights are concerned, the two outside wires behave precisely like the leads from any other alternating generator, while so far as motors are concerned, we have the power of getting our three electromotive forces 120 degrees apart, and hence have the same magnetic effect as with a three-phase system. The arrangement of lights and motors with this device is clearly shown in the diagram. It is evident that we can take from the outside wires of the monocyclic system either arc or incandescent lights anywhere and to any extent the capacity of the machine permits, working for the incandescents either two or three wire distribution at option. For a motor, two transformers are connected anywhere we please, one between the power wire and each of the outside wires. At this point the resultant phases come into play and the necessary reversal of one of the electromotive forces is accomplished by the very simple and obvious device of reversing one of the secondaries, as shown in the diagram. To the secondary circuit thus constituted, we can connect a standard induction motor which will start and run as well as if connected to a regular three-phase system, or instead of reversing one of the transformer secondaries we may accomplish the same virtual reversal of the electromotive force by reversing one of the coils in the motor itself. We therefore have a system which, so far as lights are concerned, is a simple alternating system ; so far as motors are concerned, the dynamical equivalent of a polyphase system. With a differently proportioned formation we could place upon the secondaries two electromotive forces 90 degrees apart if necessary, and then run two-phase motors instead of three-phase motors, if there were any object in so doing. Such an arrangement, however, would be less desireable than that of the quasi three-phase system, for the reason that without gaining anything in the motors we should have to generate a larger electromotive force in the teaser coil, and hence take up more room on the armature with it, perhaps enough to have an effect upon the output of the machine considered as a single-phase generator. It is sufficiently evident that the method shown would not be the only way of getting the same result. For example, in this second diagram a somewhat different arrangement is shown accomplishing precisely the same end. Here our object is to operate secondary mains on the Edison three-wire system, and in connection with them to run motors at any point we please. A large transformer, to which the secondary is connected on the three-wire system, is, therefore, installed, and the secondary mains distributed in any manner we please. A second and small transformer, proportioned to the total amount of motor service desired, is connected as shown in the diagram, and the power wire leading from it is taken through the whole or part of the three-wire system. The device is analogous to the arrangement of the generating coils themselves, and the result is the ability to operate a standard induction motor by connecting it anywhere on the three-wire system to the two inside wires and to the power wire. Such an arrangement as this is immensely convenient in distributing power and light in cities where, for example, it is desired to establish an extensive system of secondary mains through Edison tubes, or other convenient underground distribution. It is, furthermore, interesting to know that one is not confined to the use of either two or three-phase induction motors, since a monocyclic generator connected to the primary circuit makes an excellent synchronous speed without the assistance of a starting motor, in this particular being vastly superior to the pure single-phase synchronous machine. But, it may be asked, how about this power wire? In case, for example, of a transmission over a considerable distance before the distributing point is reached, must the power wire be part of the transmission system? In answer, I need only call your attention to the fact that the essential point of the monocyclic system, so far as motors are concerned, is the establishing of an electromotive force bearing the same relation to the system as is borne by the teaser coil of the generator. Consequently, in case of a transmission plant, the main generators at the distant station may be simple single-phase machines, the subsidiary electromotive force being furnished by a synchronous motor or similar device at any point in the system. So we might readily have an extensive transmission with a monocyclic machine in the sub-station of such size as is necessary to furnish current for what motors may be upon the system. The power wire would then run only to the sub-station. Another interesting peculiarity of the monocyclic system, and one which is not without importance in case of an extensive power distribution, is the following:

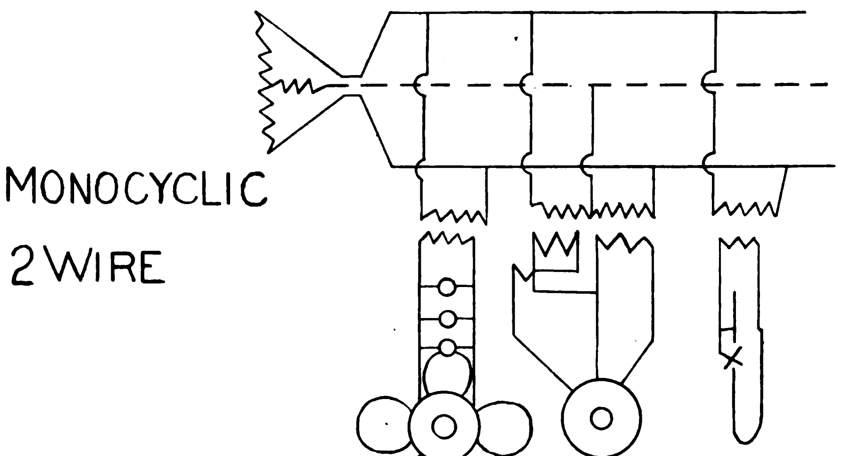
Under ordinary circumstances, induction and synchronous motors are wound so that the counter electromotive force affects the system in a perfectly symmetrical manner, and the current flows over all the wires with some degree of symmetry in response to the demands of the motors on the system. It is customary, however, in the monocyclic system, to employ motors so wound as to throw a high counter electromotive force into the power wire when the motor is at speed and loaded, thereby reducing the normal current carried over the power wire to a purely nominal amount, and this can evidently be done without sacrificing much in the matter of starting, since at the start all the counter electromotive forces in the motors are zero. We have, then, a motor system of a type really peculiar to the monocyclic system, in that each motor will start under the same conditions of impressed electromotive force as if it were a polyphase motor ; while, when at speed and loaded, it would be operating virtually as a single-phase machine. If, however, it were overloaded so that it would tend to slow down or stop, sufficient energy would flow over the power wire to bring it back to speed, just as if it were a polyphase machine. This is only one of various interesting ramifications in the system when developed to meet special conditions.

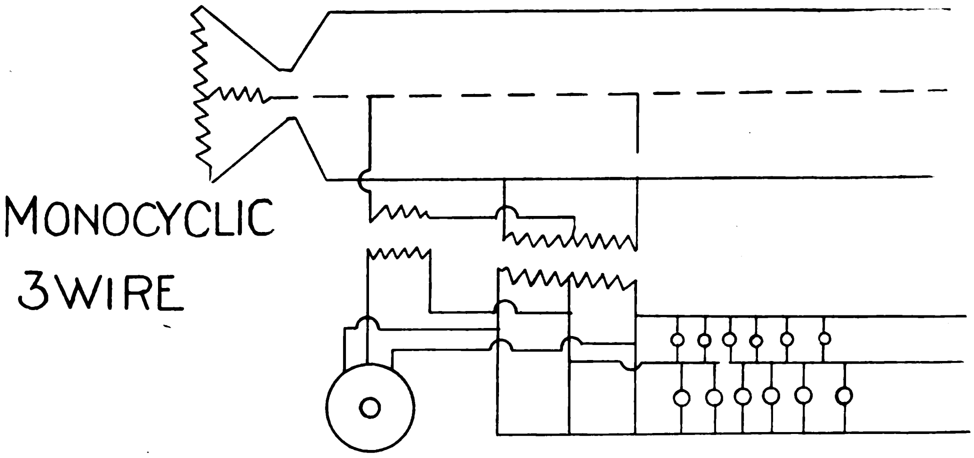
The connections shown in the diagram, however, are those of the most direct applicability and probably which would be most extensively used for central station service. At this point it may be appropriate to ask what is the disadvantage of such a system. It evidently secures exceedingly marked advantages in the ability to operate the lights on existing circuits or with the simplest possible kind of distribution, and at the same time to run at any point in the system synchronous or induction motors of well tried and familiar types. The question can be readily answered ; in fact, the question is almost obvious. The price which we have to pay for this advantage is the installation of the power wire which necessarily adds something to the weight of copper in the system and to the trouble of installation. Under all ordinary circumstances the power wire need be of trivial cross-section compared to that of the other wires, since, as a rule, the energy required for operating the motors from the given central station is small compared with the total capacity of the stations ; and further, it is worth remarking that the monocyclic motors, either synchronous or induction, will run perfectly well if the power wire is disconnected after the motor is at speed, operating them as single-phase machines. It is, of course, well known that the single-phase synchronous motor gives admirable results, and it is also true that a single-phase induction motor can be constructed of excellent efficiency and other electrical properties. The only material difficulty in this case is to get the motor to start with a good torque. The monocyclic connection enables this to be accomplished. After the motor is at speed the power wire becomes no longer necessary to successful operation, so that in spite of the necessary existence of the power wire it is easy to see that the additional amount of copper is not likely to be burdensome in central station operation. It would hardly ever be necessary to install a power wire of more than one-fourth the joint cross-section of the others, as given in the diagram, and generally a much smaller wire will suffice.

I have thus endeavored in a brief space to give a good working idea of the monocyclic method of combined light and power distribution which has been devised, and is urged upon the public as specially adapted for the work of central station distribution on account of its unique simplicity in practice. As to what has already been done in the installation of such apparatus, a considerable number of these monocyclic generators are in









daily use in central stations, for the most part operating over circuits already established, and displacing the higher frequency alternators which had been previously used. They are giving excellent results, and the operation of the motors, wherever employed, has been highly satisfactory. The system, therefore, needs no extensive exploitation on paper. After once pointing out here the principal and general advantages of the system, it is better to let the plants already running speak for themselves, and let their verdict be final.

BOOK REVIEWS.

Elementary Lessons in Electricity and Magnetism. By Silvanus P. Thompson, D. Sc., B. A., F. R. S., F. R. A. S. Cloth, 8vo, 607 + xix. pp. Illustrated. Price, $1.40. New York and London: Macmillan & Co., 1895.

The complaint is frequently heard that we have no good elementary text book of electricity, and while this has not been entirely without foundation, the fact has remained that the literature on the subject of electricity that has been of a suitable character to be safely placed in the hands of the student in preparation for a course of training in electrical engineering has been lamentably small. Better, however, that there should be a single good text book than that there should be thousands of bad ones, and in this little work we have what we can praise without reserve.

Prof. Thompson is too well known as an author to require any introduction to the readers of Electricity, for his works, so far as they cover the electrical field, are acknowledged everywhere as standard. But the writing of a text book for experts, or for those who have already had an introduction into the science, and the writing of one which shall in every way be suitable to those who are seeking to qualify themselves for such an introduction, are two entirely different and distinct undertakings.

Of the two the latter is by far the more difficult of fulfilment, requiring the qualifications both of the teacher and of the constructor. Fortunately the author combines both of these in a high degree, and brings to his assistance an unusually broad knowledge of the science, such as few writers of elementary text books possess. Added to these is that clearness of diction and perspicuity of statement which have characterized his larger works, and to which they owe so much of their popularity.

Among the most successful of elementary text books of science are Roscoe's Elementary Chemistry and Lockyear's Elementary Astronomy. In both of these the attempt has been very successfully made to give a clear skeleton outline of the science, upon which later the student may build the more substantial structure. The plan in both has been to give without too much detail *all* the essential fundamental facts of the science. Other authors have attempted this, but most of them have failed of success in that they gave too much. It requires a nice discrimination to stop just at the proper point, to give neither too little nor too much, for both faults would be equally fatal. In the text books referred to the plan is adopted of giving at the end of the book a series of questions, including problems, covering all that is embodied in the various chapters. These questions are also arranged under the same headings as the chapters to which they refer, and as every student who has been fortunate enough to have been brought up on them knows, form one of the most useful features of the books. It makes them self-teachers, as it were, and proves likewise of assistance to the instructor.

Prof. Thompson has constructed this book exactly on these lines, and has used rare judgment in collecting a mass of facts underlying the science which will be useful in further study and upon which further study must be based.

Of course such a text book to continue of value must be kept up with the times, and the new facts in the science added from time to time in new editions.

The original edition of this work appeared in 1881. The one under review bears the imprint of 1895, and involves many changes and additions rendered necessary by the progress of the science.

As stated in the preface, "In the thirteen years which have elapsed much addition has been made to our knowledge, and many points then in controversy have been settled." The book is therefore now up to date, and we congratulate ourselves, as well as others interested in the cause of education, on the possession of a text book on electricity in every way the equal of Roscoe's elementary text book on chemistry. We think we can scarcely accord higher praise than this.

Electric Transmission of Energy. By Gisbert Kapp, Mem. Inst. C. E., M. Inst. El. E. Fourth Edition. 8vo, 445 pp. 166 Illustrations. Price, $3.50. New York: D. Van Nostrand Co.

Since the issue of the third edition of this well known work in 1891 an enormous development has taken place in every branch of electric power transmission, and the polyphase system has had its development entire. Installations such as those at Lauffen, Rome, Genoa, etc., have made long distance transmission an accomplished fact where before it was at best but a promise of the future. Electric motors in lieu of long lines of shafting and many other developments in the line of electrical transmission have come into practical use, making a new edition almost imperative. In preparing this it became necessary to re-write a large portion of it, incorporate what was new, and omit that which the author thought would best bear omission. He wisely concluded to omit entirely the historical part, the detailed descriptions of plants, and comparisons of electric with other systems of transmission, which in the present state of development no longer add to the value of the book. Special works devoted to certain branches upon which he had touched in the previous edition, such as electrical traction, etc., both overhead and underground, also rendered the continuance of these portions no longer desirable. On the other hand, the theory of continuous current machines has been somewhat extended, and that of alternators and multiphase apparatus added. This we consider the most valuable feature of the work. The chapter on the line has been considerably enlarged, especially that portion relating to the most economical proportioning of the weight of copper to the line losses. In fact this chapter seems to be a complete development of Sir Wm. Thomson's economic law to meet every contingency, and adds very much to the value of the book.

An omission that we are sorry to see in a book in other respects so fully up with the times is that of sufficient attention to the subject of transmission of energy at constant current. Some space is devoted to the governing of motors, etc., operated by this system, but practically nothing is said of the economies resulting therefrom or attainable under the trying conditions imposed by electric traction. Heretofore our electric railways have had to deal with areas rather than with distances, and under these conditions the constant potential method of distribution has proved fairly satisfactory and economical, but with the extension of these lines to meet interurban service, distances instead of areas must be considered. With the constant potential distribution the best that can be done will involve an investment in copper proportional to the *square* of the distance and a loss in transmission in proportion to the *square* of the distance, whereas the expected traffic can be expected to increase only as the distance. On the other hand, in distributing by constant current both investment in copper and line losses will be proportional to the traffic or as the distance. It would seem, therefore, that the claims of the constant current, which must eventually supplant the constant potential method of distribution in long lines, should have received more attention, especially since the author has given elsewhere so much attention to economies in line construction under the constant potential method. He can scarcely be ignorant of the recent developments in the adaptation of the constant current to traction, for they have been widely published both in this country and abroad.

With this striking fault of omission, which we hope to see rectified in a future edition, the present seems to be fairly well up to the times, and will make a valuable addition to the specialist's library.

Method for Obtaining Alternating Current Curves.

BY DR. LOUIS DUNCAN, JOHNS HOPKINS UNIVERSITY.

In some cases a telephone method for obtaining the curves of alternating currents and electromotive forces is very convenient.

The method ordinarily employed for obtaining current curves is to shunt from a non-inductive resistance in the circuit, and include in the shunt circuit a contact-making arrangement on the dynamo shaft, a telephone, and an electromotive force, due to a constant current. This constant current is adjusted until there is silence in the telephone. When this occurs, the fall of potential due to the alternating current is equal to the fall of potential due to the continuous current, and knowing the latter, we get the value of the alternating current at the instant the contact on the shaft is made. Electromotive forces may be obtained in the same way by balancing a continuous electromotive force against the instantaneous value of the alternating electromotive force when the contact on the shaft is made.

There are several difficulties in this arrangement. Any small thermal electromotive force at the contact makes it difficult to get even an approximate balance, while only one curve may be obtained from a single contact-making arrangement on the shaft. I have employed with some success a method in which some of these difficulties are eliminated. To a telephone diaphragm, made preferably of mica, I attach a small coil of fine wire. Beneath the diaphragm are two coils wound together, and so placed that the diaphragm coil is in a magnetic field due to currents flowing in them. Through the diaphragm coil I send instantaneous currents obtained from a contact-making device on the shaft, there being a battery in circuit with the coil and the contact maker. Through one of the stationary coils I send a current proportional to the electromotive force to be measured, or a current obtained from a shunt on a non-inductive resistance in the dynamo circuit. The other coil has a continuous current flowing through it, which latter is measured. I now adjust the continuous current until the sound in the telephone is zero. If the coils are equal, this will mean that the continuous current is equal to the instantaneous value of the alternating current when the intermittent current is made. It will be seen that the method is independent of any small electromotive forces due to the contact, and any number of curves may be obtained from the same contact making device.

This method is fairly sensitive, and gives good results. It has, however, the difficulty of all telephone methods, that unless the contact only lasts for an infinitely short time there will always be a sound in the telephone. By making a sharp contact, and after some practice, the results are good.

THOSE IN ATTENDANCE AT THE CLEVELAND CONVENTION.

Abadie E. H., Wagner Electric Mfg. Co., St. Louis.
Ackerman P. C., American Electrical Works, New York.
Adams T. E., Brush Electric Co., Cleveland.
Ainsworth F. F., A. Lovell & Co., Chicago.
Alberger Louis R., Henry R. Worthington, New York.
Alexander P. H., Electric Selector and Signal Co., New York.
Almstead, Rochester, N. Y.
Angle Harrison M., Chicago Cross Arms Co., Chicago.
Armstrong E. A., Camden Lighting and Heating Co., Camden, N. J.
Atkins W. H., Edison Electric Illuminating Co., Boston.
Ayer Jas. I., St. Louis.
Babcock E. L., Falls Rivet and Machine Co., Cuyahoga Falls, Ohio.
Babcock C. A., Falls Rivet and Machine Co., Cuyahoga Falls, Ohio.

General News.

What is Going on in the Electrical World.

Gainesville, Ga.—A movement is on foot to organize a company to build an electric street railroad in Gainesville.

Fremont, O.—Smith & Schertzer have purchased the Gibsonburg electric light plant, which recently made an assignment.

Ft. Worth, Tex.—D. R. Fant has been appointed receiver of the Weatherford Electric Light, Power and Water Company.

Winchester, Ind.—The electric light building here was totally destroyed by fire on the 15th, entailing a loss of about $10,000.

Toronto, Can.—City Engineer Keating recommends the installation of a municipal plant for the electric illumination of the city streets.

Troy, N. Y.—City Engineer Sherwood claims that Troy pays too much for its light, and favors competition in the awarding of the contract for lighting.

Lorain, O.—A survey is to be made at once of three suggested routes for the proposed Lorain and Wellington electric railway and the best one adopted.

Portland, Me.—The mayor and aldermen have given the Portland Railroad Company permission to use electricity for propelling its street cars.

Winona, Minn.—It is understood here that a reorganization of the Winona General Electric and Street Railway Companies will soon take place.

Sheboygan, Wis.—The electric lighting company's contract for lighting the city has expired, and the council has called for bids by advertisement.

Manston, Wis.—A number of our citizens have decided to form an organization for the purpose of securing electric lights, waterworks, etc.

Shelburne Falls, Mass.—Arrangements have been made for a survey of a route for the proposed electric railway between this place and Coleraine.

Frostburg, Md.—The Frostburg electric light plant was sold on the 18th inst. at trustees' sale. Dr. J. J. Jones, a former stockholder, bought it for $7,100.

Chicago.—The Calumet Electric Street Railway Company has filed a trust deed to the Equitable Trust Company to secure $3,000,000 gold construction bonds.

Wallingford, Conn.—The people of this borough have voted in favor of electric lights, and will ask the Legislature for permission to erect and operate a plant.

Stanton, Mich.—Stanton has decided to submit to the people the question of bonding the city for $6,000 for the purpose of putting in an electric lighting plant.

Bristol, Tenn.—The Bristol gas, electric light and power plant has been purchased at public sale by the Glamorgan Iron Works of Lynchburg, Va., for $20,000.

Philadelphia, Pa.—The new Hotel Philadelphia, work on which will begin early in March, will have five electric elevators, electric lights throughout, electric call bells, etc.

Galveston, Tex.—The Woollam's Lake street car line is being changed to an electric system. In a short time the drowsy tinkle of the mule car-bell will cease to be heard in Galveston.

Gloucester, Mass.—The Worcester Construction Company has contracted to build the electric street railway from Gloucester through Essex to Beverly. The line will be eighteen miles long.

Atlanta, Ga.—The Atlanta Electric Railroad Company, recently organized, will build a trolley road from some central point in the city to the old waterworks property as soon as they obtain a franchise.

Indianapolis, Ind.—The Citizens' Street Railroad Company are getting twenty-five new motor cars from St. Louis. The new cars are of large capacity and provided with the latest devices.

Helena, Mont.—In a discussion in the city council on the electric lighting contract last week one of the aldermen intimated that a new electric company would probably be organized here at an early day.

Buffalo, N. Y.—Mayor Jewett suggests the utilization of the trolley railways for carrying all street garbage out of the city from collecting stations established at convenient places along the railway routes.

Niagara Falls.—Petitions have been circulated here to raise funds for an electrical celebration on a grand scale when the first of the big dynamos is set in motion and the wheels and shafts begin to turn.

New York.—The Brotherhood of Electrical Workers submitted a proposition to the Electrical Contractors' Association making eight hours a work day which the latter refused to accept, and the workers to the number of eight or nine hundred went on strike Tuesday of last week and are still there.

Brooklyn, N. Y.—The board of aldermen have voted to extend the rights of the Municipal Electric Light Company over the entire city, with the understanding that at the end of ten years the municipality may take possession of the plant upon the payment of a sum equal to the cost of the plant.

Savannah, Ga.—It is probable that in a few days the receiver of the Electric Railway Company will be dismissed, the company reorganized and financial arrangements made that will give permanency to the concern.

Quincy, Ill.—The ordinance committee of council has reported in favor of granting a franchise to the Empire Electric Light and Power Company to erect poles and wires in the streets for lighting purposes.

Washington, D. C.—The District Commissioners have granted a permit to the Eckington and Soldiers' Home Railroad to equip four miles of its line with the underground electric system owned and controlled by the Electro-Magnetic Traction Company, of which organization Senator Stewart is president and Senator Hunton vice-president.

Albany, N. Y.—The common council has resolved "that the Committee on Applications to the Legislature, together with the corporation counsel, be and they hereby are authorized and directed to secure such necessary legislation as may be required to submit to the citizens of Albany at the next charter election to be held in said city of Albany, a proposition that the said city of Albany be authorized and empowered to erect, maintain and equip an electric lighting plant for the purpose of lighting the streets of said city by electricity, and for furnishing light and power for commercial purposes, and for the further purposes of lighting by electricity the public buildings, school houses, station houses and engine houses in said city."—A bill introduced in the Senate provides for the appointment of an inspector of electric meters at $5,000 salary, by the Governor; he to appoint five deputies who shall respectively reside in Buffalo, Brooklyn, Rochester, Syracuse and Utica; salary, $1,500. –The Senate Cities Committee on the 19th gave a hearing on the Owens bill fixing the price of electric lights in cities of 800,000 or over at one-half cent. per hour per light for incandescent lights, and not more than 4 cents per hour for arc lights. Paul D. Cravath, representing several electric light companies, opposed the bill. He said that not one of the companies had paid a dividend in five years. Mr. U. G. Lewis, representing the Edison Electric Illuminating Company, argued against any interference with the business at this stage. Robert Payne, representing the Municipal Light and Power Company of Brooklyn, spoke in the same strain and closed the hearing.

Telephone and Telegraph.

A movement is now on foot in Tonawanda, N. Y., to organize a local telephone company to operate wires and instruments in the Tonawandas. Though the scheme is yet in embryo, it is securing the sanction and support of local business men.

Live Oak, Fla., has shown itself entitled to the spirited adjective in its name—it has a telephone line, electric lights and a new ice-making plant, and the lumber mills there have more orders than they can fill.

An opposition telephone company has secured a franchise in Port Huron, Mich., and, having obtained 350 subscribers, is ready to do business at rates of $24 for residences and $30 for business houses. Now the Bell people announce that hereafter all their telephones within a mile of the exchange will be rated at $18 for residences and $24 for business houses, which is half the old figures.

The business men of Catlettsburg, Ky., have decided to put in a telephone system there to be operated at the lowest possible rates. At Ashland also there is talk of opposition to the East Tennessee Company.

T. C. Duncan, George H. Oetzel, W. E. Thomason, Wm. A. Nicholson and W. D. Wilbur have been commissioned by the State as corporators of the Union Telephone Company, the object of which is to operate a telephone exchange at Union, S. C. The capital stock is $1,000.

A charter has been granted the Anderson Telephone Company of Anderson, S. C. R. E. Ligon has been elected president, W. R. Osborn vice-president, and L. R. Brock secretary and treasurer.

The Virginia Telephone Company, of Norfolk, Va., having obtained a charter, have asked the Norfolk council for a franchise permitting them to establish a telephone plant. They guarantee an efficient service for two thirds of the current rates.

The hearing of the motion of Lawyer Simon Sterne for a permanent injunction against the Metropolitan Telephone and Telegraph Company of New York, which was down for Feb. 18, has been adjourned until March 7 as the result of an agreement between counsel on either side. The injunction is pending an action to restrain the company from increasing the present rate of $150 paid by Sterne for the company's service to a yearly rental of $240.

J. H. Childers, of Hermitage, Hickory County, Mo., will commence at an early day the construction of a telephone line from Sedalia to Springfield, Mo.

The Central New York Telephone and Telegraph Company are preparing to make important additions and changes in their plant for the purpose of improving their service in Syracuse, N. Y.

The business men of Beaumont, Texas, have petitioned the Western Union Telegraph Company to establish a telegraph line between Beaumont and Sabine Pass.

Some enterprising citizens propose erecting a telephone line between Perry and Elcho, Ga.

Several hearings have been given at Albany by the legislative committees to business men and representatives of the telephone companies in regard to the provisions of the Parsons Gerst telephone rate reduction bill. At the hearing on the 19th inst. arguments were made against the bill by General B. F. Tracy on behalf of the Metropolitan Telephone and Telegraph Company of New York City; by John G. Milburn for the Buffalo Telephone Company, and by Mr. Babcock, of Elmira, representing the New York and Pennsylvania Telegraph and Telephone Company. The hearing was then adjourned for two weeks.

The city council at Lansing, Mich., has passed a resolution instructing the city clerk to correspond with the Harrison and Standard Telephone companies with a view of inducing them to establish a telephone system in Lansing to compete with the present company.

The Indiana Telephone and Construction Company have applied for a franchise to establish a telephone system in Muncie.

Frankfort, Ind., has lately been surfeited with telephone promoters and projects. The Stetaphone Company has its plant about ready for operation, and test lines have been put up in the city by the Phœnix and the Stroger companies. The Phœnix and the Stetaphone people have secured a large number of subscribers. In the meantime, the Central Union, which has been in operation about four years, is losing its customers by the dozen.

The break in the Commercial Cable Company's cable off Robbins Reef in New York harbor has been repaired. This was the cable laid in the harbor and through the Narrows to Coney Island a couple of months ago to connect the ocean line directly with the office in the city. The cable was broken by the dragging anchor of some vessel forced from its moorings by drift ice.

The Southwestern Telephone and Telegraph Company has begun work for the erection of poles in Taylor, Texas. Other work for putting in the telephone plant will be pushed along as rapidly as expedient.

The Harrison Company reports having between 400 and 500 contracts for telephones in Terre Haute, Ind.

The Bell Telephone Company is preparing to spend $160,000 for underground conduits in Cincinnati the coming summer.

The annual report of the Central New York Telegraph and Telephone Company read at the meeting held in Utica gives its total subscribers as 2,951, a gain during the year of 66. There are 353 toll stations and 234,047 toll line messages were transmitted at the average rate of $24\frac{3}{8}$ cents each, which covers the message and reply. The average cost of each call to each subscriber in Utica is $2\frac{3}{10}$ cents.

Attorney-General C. C. Watts, of West Virginia, about a year ago instituted a suit against the Bell Telephone Company for $9,000 damages, which he claimed for the destruction of his residence and contents by fire communicated by the electric wires of that company at the point where they entered the building. The case resulted in a verdict for the plaintiff for the full amount with costs. The defence appealed it to the United States Court of Appeals, and a few days ago Justice Morris handed down an opinion affirming the judgment.

Within a radius of 33 miles of New York City there are 3,500,000 people and 25,000 telephones. In New York City proper there are 10,500 telephone stations, 90 per cent. of which are equipped on the metallic circuit system. In that city the Metropolitan Telephone and Telegraph Company operates ten central exchanges, seven of which are entirely for metallic circuit service. The New York and New Jersey Telephone Company has 10,000 subscribers, about 75 per cent. of whom enjoy the metallic circuit system.

The House of Representatives has refused to adopt the Senate amendment appropriating $500,000 to begin the laying of a cable to Hawaii. It seems likely that the large majority—152 nays to 114 yeas—against the cable will prevent its acceptance in conference.

A telephone company is forming in Pensacola, Fla. Three-fourths of the $8,000 capital stock has already been subscribed.

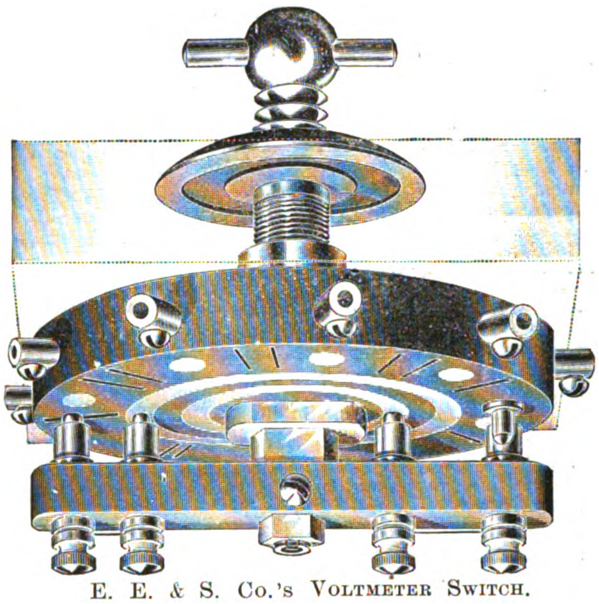
A new telephone system is being considered in Albany. It is proposed to place telephones in several places easy of access where anyone who wishes to send a notice or a paid advertisement to any of the Albany papers can do so with very little trouble. The plan was submitted some time ago to several of the newspapers of Albany It has been proposed to place these instruments in branch offices, in stationery or drug stores in remote parts of the city and suburban adjuncts. The offices will be kept open all day and until late at night. The promoters of the scheme have tested five telephones connected with a mile of wire with satisfactory results. The tested instruments were the Phœnix, Harrison, D'Unger National and Colvin.

A New Voltmeter Switch.

Among the new switchboard appliances manufactured by the Electric Engineering and Supply Company, Syracuse, N. Y., is that of a Voltmeter Switch, shown in the accompanying cut, and described in brief as follows:

From the front of the switchboard nothing is visible but a 2½-inch dial plate, similar to that of a safe lock, and upon which are numbered graduations corresponding to the respective number of circuits. A movable dial carrying a pointer, is rigidly fastened to a fiber or hard rubber cross-bar that sweeps over the surface of the switch base.

It will be noted that there are two metallic rings embedded in the base. To these the voltmeter leads are electrically connected; the line contact points are spaced around the outer edge of the base. All wire connections of contact points, and both rings, radiate from the edge of the base, the connector of the inner ring being insulated by a hard rubber tube where it passes through the outer ring.



E. E. & S. Co.'s Voltmeter Switch.

The cross-bar carries on each radius a pair of plungers, connected together in pairs with fuse wire, held under thumb nuts, to protect the voltmeter against possible raise in potential. This combination completes the circuit between the voltmeter and the lines terminating in the diametrically opposite contact points upon which the outside plungers rest.

The standard size of swicth is adjustable to boards varying in thickness from three-fourths to an inch and five-eighths. To obviate accidental short circuiting of contact points, because of wiping of plungers over the base, two cuts are made in the base between each pair of contacts and in the path of the plungers.

The chief merit of this switch is that it is compact and self-contained, the only labor necessary in applying it to a switchboard being that of boring an inch hole, screwing the parts together and making the electrical connections at the back of the board.

The Electrical Engineering Company's Catalogue.

Catalogue No. 3 of the Electrical Engineering Company of Minneapolis, Minn., just published, is a book of 298 pages, large 8vo, and is the most comprehensive work of the kind that has come under our notice for a long time. It is neatly printed, full of engravings portraying almost every article used in the electrical business, and has remarks and tables giving every particular—whether of size, weight, gauge, dimension, application, composition, quality or price—which might serve to enlighten the purchaser on the various points of the article he is seeking. In the latter part of the book there are tables showing differences between wire gauges in decimals of an inch; diameter of magnet wire insulation: dimensions and resistance of pure copper wire; weights of iron, steel, copper and brass wire, diameters determined by American gauge. There are also rules for estimating resistance; wiring rule for determining the proper size of wire for electric light and power circuits, either direct or alternating, at any pressure; and rules and requirements for the installation of wiring and apparatus for electric light and power, taken from the National Code, as recommended by he Underwriters' National Electric Association, January, 1895. An alphabetical index is appended which enables one to find what he is after without loss of time or patience. The Catalogue, taken as a whole, does great credit to the compiler and to the enterprising company whose extensive business it so well illustrates.

COMMERCIAL PARAGRAPHS.

Business with the Metropolitan Electric Company of Chicago is brightening up and increasing considerably. They are having a great many inquiries for their I. X. L. Triple Braided Weatherproof Line Wire. Electric light, electric power and street railway, telephone, telegraph, police, messenger and fire alarm service companies and all others interested in the use of insulated wires for overhead or aerial work, and desiring a superior article at a moderate cost, will do well to confer with them before purchasing elsewhere. The indications are that the spring and year of 1895 business with them will be very large.

Mr. N. S. Amstutz, Mechanical and Electrical Engineer, located at Cleveland, O., has recently moved his office from 506 The Cuyahoga to Room 29 Blackstone Building, where he is prepared to carry on all the details of his profession. A number of new electrical devices are about ready for the market, and will soon be placed on sale by prominent concerns for whom Mr. Amstutz has designed their entire line of specialties. This class of work, as well as general installation supervision, is carefully attended to by Mr. Amstutz.

The Metropolitan Electric Company of Chicago are sending out circulars, advising the trade that they carry in stock the celebrated Hoffman Rod Polish.

The Metropolitan Electric Company, 186 Fifth avenue, Chicago, have found that the Knapp Sellner Adjustable Desk Lamp Holder is attracting considerable attention. It is found to be just what is required for desk light.

RECENT COMPANY ELECTIONS.

Detroit Citizens' Railway Company, Detroit, Mich. Hon. Tom L. Johnson has been elected president in place of J. M. Edwards, who resigned; vice-president. J. C. Hutchins. Directors: Tom L. Johnson, vice J. I. Johnston, resigned; R. T. Wilson, M. O. Wilson, R. T. Wilson, Jr., J. M. Edwards, J. C. Hutchins, F. W. Van Name, Cameron Currie, John C. Donnelly.

Bell Telephone Company, Philadelphia. President, James Merihew; secretary, Samuel B. Huey: treasurer. A. A. Ziegler. The old board of directors were re-elected.

New York, Westchester and Connecticut Traction Company, New York. President, Ex-Senator Wm. Cauldwell; vice-president, Daniel F. Cohalan; treasurer, Philip Katz; secretary, John Foley, Jr. Executive committee: Martin J. Keogh, Franklin A. Wilcox, Daniel F. Cohalan.

Detroit Electric Light and Power Company, Detroit, Mich. President, F. F. Palms; vice-president, George Vail; treasurer, W. S. Crane. Wm. B. Moran, who resigned the presidency a short time ago, was retained on the board of directors.

Parkersburg Electric Light and Power Company, Parkersburg, W. Va. President and treasurer, C. C. Martin; secretary, W. W. Van Winkle. Directors: C. C. Martin, W. N. Chancell r, W. Vrooman, W. W. Van Winkle, J. A Wetherell, B. D. Spilman and John Busch.

Cohoes City Electric Railway Company, Cohoes, N. Y. President, Urban Weldon; vice-president, J. W. Himes; treasurer, Murray Hubbard; secretary, Sil s Owen. Directors: Urban Weldon, J. W. Himes, John Garside, G. E. Simmons, Hugh Graham, Silas Owen, Egbert W. Lansing, Herman Kahn, Murray Hubbard.

Central New York Telephone and Telegraph Company, Utica. Directors: A. C. Belden and Martin A. Knapp, Syracuse; David B. Parker, Buffalo; L. H. Lawrence, C. A. Nicholson, R. S. Williams and F. G. Wood, Utica.

Hartford Electric Light Company, Hartford, Conn. President, A. C. Dunham; vice-president, E. B. Bennett; treasurer, D. W. Barney; secretary, D. P. Cotton. Directors: A. C. Dunham, William H. Bulkeley, W. O. Burr, Atwood Collins, E. B. Bennett, Henry Roberts, Rodney Dennis, D. W. Barney, E. K. Root, Lucius F. Robinson and W. L. Robb.

Gulf Coast Electric Railroad Company, Biloxi, Miss. President, A. M. Dahlgren; first vice-president and general manager, J. B. Cable; second vice-president and auditor, S. W. Bennett; secretary, J. V. Ross. The capital stock of the company was placed at $500,000 at a recent meeting of the grantees and projectors.

Wisconsin Telephone Company, Milwaukee. President, H. C. Payne; vice-president and treasurer, F. G. Bigelow; secretary and general manager, John D. McLeod; general superintendent, E. B. Cottrill. Directors: H. C. Payne, F. G. Bigelow, Charles Ray, B. K. Miller, Sr., C. G. Stark, A. G. Fuller, Charles F. Pfister, Jesse Stone of Watertown, and W. A. Jackson of Detroit.

INCORPORATIONS.

The Sigourney Electric Light and Power Company, Sigourney, Iowa—to generate and furnish electricity for light and power in Sigourney. Capital stock, $8,000. Promoters: H. C. Brown, W. S. Harlan, H. O. Schipper, C. M. Harlan, E. Laffer, Sigourney.

O. I. Newton's Sons Company, Sparta, Wis.—to operate and own electric light plant, etc. Capital stock, $50,000. Promoters: Harry N. Newton, Geo. N. Newton, F. N. Newton.

The Florence Belt Line Railway Company, Florence, Col.—to build and operate an electric street railway in Florence. Capital stock, $25,000. Promoters: E. M. Weil, S. Siess, Leon Siess, C. L. Huff, all of Florence; James B Crandall, Denver.

The Universal Engineering Company of Baltimore City, Baltimore, Md.—to do a manufacturing, mechanical, and industrial business; to manufacture and sell electrical instruments, machinery, and supplies; construct, own, and operate telegraph and telephone lines. Capital stock, $10,000. Promoters: Geo. W. F. Vernon, Theo. F. Wilcox, Wm. J. Klug, Julius Stern, Leopold Stern.

The Little Falls and Herkimer Street Railway Company, Little Falls, N. Y.—to build and operate a street surface railroad, from Herkimer to Little Falls, a distance of eight miles. Capital stock, $10,000. Directors: Clinton Beckwith, John F. Henderson, Horatio P. Witherstine, Robert Earl, George A. May, Earnest R. Steele, of Herkimer; John V. Quackenbush, of Mohawk; Nelson J. Davis, of Utica; R. F Lansing and Charles Bailey, of Little Falls.

The Nantasket Electric Street Railway Company, Hull, Mass.—to operate and construct an electric street railway from Hull. Capital stock, $12,500. Promoters: Jno. L. Mitchell, Geo. E. David, Wm. F. Taylor, Hull: Jno. C. Flood, Boston, Mass.

The New York, Westchester and Connecticut Traction Company, New Rochelle, N. Y.—to build and operate a street surface road, sixteen miles long, in Westchester County. Promoters: M. J. Keogh, New Rochelle, N. Y.; F. A. Wilcox, D. F. Cohalan, J. A. Bensel, all of New York City.

The Suburban Gas and Electric Company, Revere, Mass.—to generate and furnish electricity for light, heat and power. Capital stock, $75,000. Promoters: Arthur Perry, Wm. Whitney, Allston Burr.

The Marion Water Company, Jersey City, N. J.—to construct, maintain, and operate water works, gas works, and electric light works in the city of Marion, Ohio, and elsewhere, etc. Capital stock, $250,000. Promoters: Alfred G. Brown, Lewis Hallock, Jr., Robert H. Dillingham, Herbert F. Hatch, East Orange, N. J.; Chas. N. Brown, Jersey City.

The California Telephone and Construction Company, San Jose, Cal.—to buy, rent, sell and otherwise deal in telephones and in all instruments used in connection therewith; to own and control telephone lines, all kinds of electrical instruments, etc. Capital stock, $500,000. Incorporators: H. O. Hickox, L. M. Hale, F. M. Burkholder, Walter M. Field, Wallace C. Stratton, Thomas Clark, Nicholas Bowden, Chas. E. Severance, Thomas B. Hussey.

A certificate of reorganization of the Schenectady Railway Company by the purchasers at the foreclosure sale, has been filed in the office of the Secretary of State, Albany, N. Y. Capital stock, $300,000. Directors: P. F. Knowles, William Henry White, A. G. Macandrew, Geo. W. Hebard, Lewis L. Clarke and Charles A. Lieb, of New York City: Joseph Ford, George W. Jones and John Kruesi, of Schenectady.

The Atlanta Electric Railway Company, Atlanta, Ga. Capital stock, $100,000. President, Dayton Hale; secretary and treasurer, D. H. Livermore. Directors: T. B. Felder, Jr., J. C. Dayton, James W. English, Jr., William C. Hale, Charles Runette, Dayton Hale, D. H. Livermore, W. L. Seddon, L. Z. Rosser, James R. Collins, H. P. Williams.

The Fuller Electric Engineering Company, East St. Louis, Mo.—to manufacture electric apparatus. Capital stock, $30,000. Incorporators: W. A. Fuller, Charles T. Dana and G. H. Dudley.

The Phœnix Telephone and Manufacturing Company, Chicago—to manufacture electrical apparatus. Capital stock $100,000. Incorporators: R. Brown, E. E. Yaxby, J. H. Riley.

The Pacific Storage Battery Company, San Francisco, Cal.—to manufacture, buy, sell, rent and deal in electric storage batteries, dynamos and electrical supplies, machinery and apparatus; to act as agents and factors for other corporations, firms and persons transacting similar business. Capital stock, $20,000. Promoters: Thomas Addison, Berkley, Cal.; Robert B. Elder, Samuel E. Kearney, San Francisco: Fred F. Barbour, F. M. Ray, Oakland, Cal.

The West Chester and Downington Street Railway Company, West Chester, Pa.—to operate an electric street railway. Capital stock, $100,000. Promoters: Jas. McGraw, West Chester; R. J. Malone, J. W. Clark, Philadelphia.

The Felts Electric Light and Power Company, Colusa, Cal.—to purchase, lease or sell electrical rights, patents, licenses, etc., and other property pertaining to electric lighting, telegraph, telephone and electro plating. Capital stock, $100,000. Promoters: W. W. Felts, W. F. Ford, W. W. Brown, Colusa; F. F. Peart, Geo. F. Scott, J. K. Bartholomew, C. G. Felts, Geo. B. Harden, E. E. Scott, Maxwell, Cal.

The General Electric Railway Company, Chicago, Ill.—to make, acquire, own, use, manage, sell and otherwise handle or dispose of inventions, improvements, patents in railway appliances and devices, and the model patterns and samples thereof, and to acquire and operate street railways. Capital stock, $5,000,000. Promoters: Daniel M. Simmons, Wm. A. Youmans, Geo. Pfloger.

The United States and Hayti Cable Company (incorporated in W. Va.), New York, N. Y.—to construct and maintain a line of electric telegraphs, cable (submarine, etc. between the United States and West Indies, etc. Capital stock, $500,000. Promoters: Jno. W. Mackay, Virginia City, Nev.; Geo. C. Ward, Brooklyn, N. Y.; *W. Mackay, Jr.* New York City, N. Y.

ELECTRICAL PATENT RECORD.

LETTERS PATENT ISSUED FEBRUARY *19, 1895.*

ELECTRIC RAILROADS AND APPLIANCES.

534,411. Trolley-Wire Support. **Marmaduke F.** Van Buren, Philadelphia, Pa. Filed Oct. 5, 1894.

534,454. Conduit Electric Railway. Wilhelm Simon, Nuremberg, Germany. Filed March 3, 1894. *Renewed* Jan. 11, 1895.

534,475. Conduit Electric-Railway System. William L Hedenberg, New York, N. Y. Filed June 5, 1894.

534,495. Conduit Electric Railway. *Octavus* Cohen, New York, N. Y., assignor to Rebecca O. Cohen, same place. Filed May 15, 1894.

534,519. Conduit Electric Railway. Alfred *Rosenholz*, San Francisco, Cal., assignor of one-*half* to Samuel J. Clarke and Harvey S. Brown, same place. Filed May 22, 1894.

534,605. Trolley-Wire Crossing. Charles S. *Hersh* and Edwin F. Weaver, Philadelphia, Pa., assignors of one-third to Alfred E. Clarke, same place. Filed March 13, 1894.

534,613. Trolley-Wire Support. Marcus T. *Murphy*, New Orleans, La., assignor of one-half to Robert Bensberg, same place. Filed Sept. 14, 1894.

ELECTRIC LIGHTS AND APPLIANCES.

534,269. Electric-Light Switch. Harry W. Lawrence, Denver, Colo. Filed May 31, 1894.

534,424. Reflector for Arc Lamps. Carl Coerper, *Cologne*, Germany. Filed May 15, 1894.

DYNAMOS, MOTORS, ETC.

534,281. Electric-Current Distributing System. *Geo. B.* Pennock, Boston, Mass. Filed June 1, 1894.

534,288. Magneto-Electric Machine. Henry J. Smith, Pompton Lakes, N. J. Filed June 8, 1894.

534,536. Electrically-Operated Dental Engine. William E. Wheeler, Dayton, Tenn., assignor of one-half to Geo. W. Johnson and James F. Johnson, same place. Filed Oct. 6, 1893.

BATTERIES.

534,603. Storage-Battery. George A. Ford, Cleveland Ohio. Filed Aug. 11, 1894.

TELEPHONE AND TELEGRAPH APPARATUS.

534,359. Switch Device for Telephone-Circuits. Charles Clamond, Paris, France. Filed July 5, 1894.

534,373. Telephone and Signaling Circuit. Frank A. Pickernell, Newark, N. J., assignor to the American Telephone and Telegraph Company, of New York. Filed May 3, 1894.

534,547. Telephonic Apparatus. Norval L. Burchell, Washington, D. C. Filed Sept. 20, 1894.

SIGNALING APPARATUS, BELLS, ALARMS, ETC.

534,330. Electric Bell. William A. Harvey, Scranton, Pa. Filed Oct. 19, 1894.

534,364. Signaling System. William E. Decrow, Boston, Mass. Filed Dec. 31, 1892.

534,405. Electric Signaling Apparatus. Jonathan D. Price, Chicago, Ill. Filed May 5, 1894.

534,414. Railway Signaling Apparatus. William H. Walsh, Albany, N. Y. Filed Sept. 26, 1894.

534,485. Electric-Bell System for Street-Railways. Edward L. Stansberry and Jacob Bettinger, St. Louis, Mo. Filed May 7, 1894.

534,595. Electrical Alarm or Bell. George F. Atwood, Orange, and Jonas W. Aylsworth, Newark, N. J. Filed May 28, 1894.

534,597. Electrical Alarm for Street-Cars. George F. Atwood, Orange, Jonas W. Aylsworth, Newark, and Walter H. Miller, Orange, N. J. Filed May 28, 1894.

MISCELLANEOUS.

534,311. Alarm-Gauge Testing Mechanism. William H Bradt, Troy, N. Y. Filed Feb. 10, 1894.

534,318. Electric Winding and Synchronizing Device for Clocks. Charles M. Crook, Chicago, Ill. Filed June 23, 1894.

534,319. Electric Clock-Synchronizer. Charles M. Crook, Chicago, Ill. Filed July 2, 1894.

534,320. Electric Winding Mechanism for Clocks. Charles M. Crook, Chicago, Ill. Filed Dec. 15, 1894.

534,374. Electrical Apparatus for Operating Dental Implements. Oscar H. Pieper and Alphonse F. Pieper, San Jose, Cal. Filed April 30 1894.

534,481. Electric Rotary and Revoluble Air-Circulating Fan. Sherman M. Pierce, Kansas City, Mo., assignor of one-half to Chauncey S. Colton, same place. Filed Oct. 20, 1894.

534,528. Electrical Brush. Anson L. Sonn, Lansingburg, N. Y. Filed Oct. 15, 1894.

534,586. Circuit Making and Breaking Device. Samuel W. Stratton, Chicago, Ill. Filed July 2, 1894.

534,596. Electrical Conductor. George F. Atwood, Orange, and Jonas W. Aylsworth, Newark, N. J. Filed May 28, 1894.

534,608. Tower-Wagon for Electric-Line Work. John H. Leonhardt, Baltimore, Md., assignor to the Leonhardt Wagon Manufacturing Company, same place. Filed Dec. 29, 1894.

ELECTRICITY.

EDITORIAL NOTES.

The Niagara Power Company Propositions. We print elsewhere a communication from Mr. Frank C. Perkins which furnishes much food for reflection, and which is likely to attract wide attention as containing an authoritative statement of what the Niagara Power Company is willing to do or is not willing to do in the way of attracting customers at a distance.

Statements have gone abroad as to the practicability of furnishing power at distant points from Niagara in competition with locally generated steam power which have been so exaggerated as to have called for comment from us before. All such statements as these are based upon a continuous operation of the Niagara plant to its maximum capacity, which cannot be expected even under the most favorable circumstances for years to come, if ever. Until that time the fixed charges must form such a large item as to seriously interfere with commercial competition. To make this more clear let us suppose that the invested capital at Niagara is $3,000,000. At 5 per cent. on the investment, and not including depreciation, labor, taxes, etc., or interest during the constructive period, this will mean $150,000 per annum which must be made good before profits can be thought of. In other words, this will be a standing charge in lieu of a coal bill.

The Niagara Power Company offer to sell undeveloped power in 10,000 horse power lots at $10 per horse-power. At this rate they would have to have custom for 15,000 horse-power to just meet this one item. In practice it would probably amount to $200,000 or 20,000 annual horse-power. If we count in labor, taxes, interest during construction period, depreciation, and the other little items which go to swell an expense account, it seems doubtful if the scheme would be on an even paying basis until it was supplying between 40,000 and 50,000 annual horse-power at a rate of $10 per undeveloped horse-power on the company's premises. So much for the basis of our belief that the project must be a losing one for some years to come even under these most favorable conditions for the company.

They are, however, willing to bear this loss in the hopes of finally recouping themselves, so that this feature need not concern the public further than to indicate the difficulties against which the company must contend during the first few years at least in meeting competition in distant cities. The question of Buffalo is the first one to present itself, and in Mr. Perkins's paper we are given the propositions submitted by the Niagara Power Company which it may be well to consider.

The power company states that it cannot *economically* transmit to Buffalo less than 10,000 horse-power and it cannot consider the transmission of any less amount. It probably knows pretty closely what it is talking about, for Prof. Forbes has frequently stated in public that the cost of *transmission* to that point has been very carefully figured out. If this be true it also means that the city of Buffalo cannot do it any more cheaply. But 10,000 horse-power delivered at the outskirts of Buffalo does not by any means mean 10,000 horse-power that will be salable there. Nor is the problem by any means solved when the power is so transmitted. How to get it there in the most economical manner has been a matter of heated discussion, and the method finally adopted is still open to serious question, but difficult as this is as an engineering question it is a mere bagatelle as compared with that other one, of how to distribute the power when it is once delivered.

The Lauffen experiment, in which 300 horse-power was delivered at Frankfort over 100 miles of wire with a loss of but 25 per cent. in transmission, was a glorious technical triumph but a most miserable commercial failure, and yet this involved only transmission. It was the Frankfort experiment that rendered the Niagara experiment possible, but if the power company proposes to do nothing more than transmit the current it proposes to do nothing that has not already been successfully done. But it seems from the propositions before us that it does not even propose to do this. It proposes to furnish the power *at* Niagara and allow the city of Buffalo to solve the problems both of transmission and of distribution. If there were no other reasons than this shifting of responsibility, any proposition of this kind would be preposterous in the extreme. We would consider it hazardous in the present state of our experience for any one to undertake to transmit and distribute the power in Buffalo under a guarantee of satisfactory working even if he received a bonus of $10 per horse-power instead of being required to pay that sum for it undeveloped.

Then let us look at the figures offered and see what they really mean. We think it is safe to say that this transformation of the water power into electricity will not be with an efficiency of more than 85 per cent.; that the transmission efficiency will not exceed 75 per cent.; that the transformation at Buffalo will not average 75 per cent., and that the distribution in Buffalo will not be at greater efficiency than 80 per cent. This would give an ultimate efficiency of but 38.25 per cent. and make the power cost delivered over $26 per horse power. This is assuming neither fixed charges nor load factor. We know from ample experience what the effect of a given load factor is upon the cost of energy. In electric lighting stations in this country the best load factor is about 40 per cent., and this about doubles the cost of energy. We may assume that the load factor for the city of Buffalo will not exceed 60 per cent. This alone would bring the cost up somewhere near $43, and to this must be added the interest on the investment in wheelpits, wheels, side tunnels, transmission line, transformers, administration, taxes, etc., which will amount to—we do not know how much more, but it is easy to see that the figure $10 per undeveloped horse-power is not so very enticing after all. Some clue is given to one of these necessary additional charges by the power company's second proposition, which is to furnish power at $13 on the turbine shaft, and to another from its third proposition, which is $18 at the terminals of the power company's generators. Assuming it to cost $8 additional to convert the water power into electricity, we have already a cost of $51 per horse-power without considering at all the other items, which would doubtless bring the cost up, even with an honest administration, to a figure that is almost appalling in comparison with that of the undeveloped power at the Falls.

Further along in the power company's statement we are informed what it places the cost of transmission to a short distance at—viz., within the neighborhood of its hydraulic works. It states that it has contracted for $20,000 per annum to deliver 1,000 electrical horse-power to a user near by. This is a charge of $2.00 for transmission. As to the cost of transmission to Buffalo it says it cannot name a price, "as in the question of transmission are involved the *uncertainties of the loss and cost* of operation and maintenance." If the power company cannot estimate the value of these uncertainties after having some of the best engineering talent in the world engaged upon it for several years, we should like to know who can?

We think this pretty effectually settles in the negative the question of the advisability of the municipality considering these propositions.

Now as to the other statements in the proposition. The statement that the company cannot accept a time limit less than the term of its bonds is entirely reasonable. In view of all that has been done, and all that remains to be done, before the plant could be reasonably expected to be on a paying basis, a limit of thirty-five or forty years is none too long if a favorable contract can be obtained for that period. But the other statement, that the company cannot consent to the fixing of a maximum or other price within the city, is a confession of weakness and an acknowledgment of the difficulties yet to be solved that we are surprised to see made. We repeat the question—if the Niagara Power Company cannot fix a maximum price, or rather a minimum price at which they can make a profit, who can? If the city of Buffalo should buy power as suggested, it might and in all probability would, find that when it got it to Buffalo it would have something it could not get rid of at anything like what it cost. Better would the city vote a subsidy to the company to enable it to bring the power to its doors and then let it compete in the open market with other producers on the merits of its service and its price.

Mr. Perkins is sanguine of the success and honesty of municipal control. We would be more sanguine were it not for two very big "*ifs*" in the way. *If* a municipal government were as honest and efficient in business matters as a private corporation *must* be to succeed, and IF the business entrusted to its care involved no unsettled questions or untried problems, then municipal control *might* be advantageous. Unhappily, those two "*ifs*" will not down, but stand out in bold obtrusiveness in the present case.

Mr. Perkins quotes Dr. Emery's figures per annual H. P., with coal at $2 per ton, as $22. This is correct for steady working for ten hours per day. The other figures in his article are, however, for twenty-four hours per day. Dr. Emery's figures for twenty hours per day are $38. These figures, however, are only true for engines having a pretty constant load, and would be at least double if the same machinery were employed on loads similar to those obtaining in ordinary central stations. They cannot, therefore, be taken as any criterion by which to judge performance with low load factor.

* * *

Another Triumph for Young Blood. While three of our toothless contemporaries are chattering about their senility, and a fourth about its wildness and woolliness, the young blood of ELECTRICITY steps in and again carries off the palm for enterprise. We published Scott's paper with all the drawings last year a week ahead of our contemporaries, and we did the same thing this year with Bell's paper. While they are chattering, ELECTRICITY gets in its work.

* * *

The price of incandescent lamps has fallen within a few years from $1 *to* 20 *cents each. What was the cause? The competition of the independent lamp companies. For the service they have performed for the user, should they not now be remembered liberally?*

The Edison lamp is the one lamp which should be ignored.

Under the Searchlight.

The booming of Welsbach Light stock in Philadelphia continues, and about 1,000 per cent. of water is to be injected into the capital.

* * *

GENERAL ELECTRIC.

(From the Boston News Bureau.)

The General Electric Company is now earning upon the basis of above $2,500,000 net per annum, and if orders, as they have come in for the past two months, continue well into the present fiscal year which began February 1, there need be no action as respects the impairment of the capital of the company for the concern will earn itself into sound position.

The company is earning five times the amount of the preferred dividends daily accumulating, and there would seem to be no reason why, in time, these *should* not be paid.

The G. E. Company is doing the largest business *in its* history as respects the volume of its output measured in tonnage or pieces of machinery, and were the prices equal to those of three years ago, it would be earning *about 30* per cent. per annum upon its entire capital instead of having its capital selling at 30 per cent. of what it has cost most of its owners.

But even with prices on the present low basis the cost sheets have been liberally reduced by the introduction of machinery and labor-saving devices. The *company has* probably earned the past fiscal year above $1,500,000, but it has continued to charge off with a liberal hand and will shrink its assets still further in the final accounting, so that probably very little margin of earnings above what may be necessary will be shown, and the capital account, which is now all a matter of bookkeeping may be still further written down, swelling the capital deficit of last year.

But the foundation will be laid for the business of 1895, and the exhibit next year, if times are even as good as at present, should give stockholders encouragement.

General Electric directors will not talk; they have "resolved" to neither talk themselves nor allow anybody else to talk for them, but the above is not "talk": just fact which it is not our duty to conceal.

G. E. Directors will not talk. This is true. But evidently they are still ready to pay sycophants and serfs to talk for them.

If the G. E. Company is earning $2,500,000 net annually, who is stealing the money?

One thing is certain, it is not in sight.

The bank account does not grow, cumulative interest on the preferred stock is not paid, and no important investments are reported.

Meantime assets are sold from the treasury, old accounts are cleaned up, and the next annual report will show a reduction of several millions in assets.

We will grant that the company is doing as large a business as ever—in VOLUME. But what are the results?

They are losing money on every dollar's worth of goods sold.

If we consult the official records we find that, taking every article of G. E. manufacture into consideration, *their selling prices average less than* 50 *per cent. of those in force in* 1892.

They did not make money then, but paid current expenses out of the sale of bonds.

How can they make money now?

The annual meeting has been postponed as long as possible. When it is held, there will be many questions to answer, and ELECTRICITY'S representative will be there to report the proceedings.

So far Charles Albert Coffin is the only man publicly disgraced by the brief career of this remarkable company.

How long will it be until the representatives of the ancient and honorable house of Drexel, Morgan & Co. will stand, in public estimation, in the same rank as Mr. Charles A. Coffin?

THE LAMP FIELD FREE FOREVER!

Decision in the Bate Case Ends Litigation.

THE BEST LAMPS WILL WIN.

G. E.'s "Vicious" Policy Judicially Ended.

The United States Supreme Court on Monday, March 4, decided, in the Bate Refrigerator case, that the date of issue, and not the date of application, controls in deciding the date of expiration of an American patent previously patented in a foreign country.

This decision settles finally a question in patent law which has long been hanging over the industry like the sword of Damocles, ever threatening to fall and cut asunder interests of the greatest magnitude, and therefore creating a feeling of extreme unrest among those who might be affected by its descent.

The question involved is whether the date of filing an application for a patent or its date of grant is controlling in the life of a patent which is affected by the expiration of a foreign patent granted for substantially the same thing.

Section 4,887 of the Revised Statutes says that every patent granted for an invention which has been *previously* patented in a foreign country shall be so limited as to expire at the same time with the foreign patent having the shortest term.

It so happened that in the Bate Refrigerator case the patent had been applied for in this country and subsequently in Canada. The patent was not granted in this country, however, until *after* it was granted in Canada. The question arose whether the Bate patent, having been *applied* for here first, should enjoy a life of seventeen years from date of issue, or whether its life was limited by that of the Canadian patent which was first *issued* and had a life of fourteen years.

The question has been decided a number of times by the Circuit Courts that the date of *application* had nothing whatever to do with the life of the patent and that the date of issue alone controlled.

According to this decision the Bate patent, although *applied* for first in the United States, expired with the Canadian patent, which was *granted* first.

An appeal was taken from this decision to the United States Supreme Court, and since many other important patents are in the same condition precisely as was the Bate patent, the final decision has been awaited with the utmost anxiety. Among the patents so affected was the Edison lamp patent No. 223,898. The application for this was filed in the United States, November 4, 1879, and the patent was granted January 27, 1880. It would therefore expire by expiration of full term of seventeen years on January 27, 1897. Edison subsequently applied for a patent on the same thing in England on November 10, 1879. The complete specifications were filed February 6, 1880, and the great seal was attached on May 10, 1880. The life of this patent was fourteen years, and it would expire on May 10, 1894. According to the Supreme Court decision, this lamp patent also expired in the United States on this same date. Thus the hopes of a continuance of the lamp monopoly until January 27, 1897, which would have been realized had the decision been the other way, have been blasted. This decision will also have the effect of throwing out of court those cases for infringement of the lamp patent brought by the General Electric Company since the date of May 10, 1894, and doubtless affect other litigation of the same character.

The telephone patents are also affected. It will be remembered that Judge Carpenter decided the Berliner microphone patents void. These patents though only granted on November 17, 1891, had been applied for fourteen years before. An appeal was taken from Judge Carpenter's decision in the hope that it might be reversed by the Supreme Court. If a reversal could be obtained, the broad principle of variable contact transmitters might have been monopolized for seventeen years from November 17, 1891, or until November 17, 1908, provided also that the present decision had gone the other way. It matters not, however, now, whether on appeal the Berliner patents be declared valid or invalid, since by the present decision the broad principle of microphone transmitters is public property anyway.

There are still other patents affected favorably to the public by this decision. Edison obtained three patents covering broadly the use of carbon transmitters. These were all granted on May 3, 1892, and had a history very similar to the Berliner patents.

So long as these were alive they constituted a practical monopoly of microphone transmitters. These were issued to the Western Union Telegraph Company and by them transferred to the Bell Company. The validity of these patents was not affected by Judge Carpenter's decision and by their natural life would not expire until 1909. But previous to the granting of these American patents, other patents upon the same invention had been granted in foreign countries; some of these expired last year. Hence by the present decision the United States patents have also expired.

The manufacture of incandescent lamps is now free forever.

A decision in the McKeesport case is expected next Monday, deciding whether or not the Westinghouse Company has valid and unquestioned claims against the Edison interests and other manufacturers of lamps for past damages for infringement of the Sawyer-Man patent on fibrous or vegetable filaments. But inasmuch as all good lamp makers now use a structural filament, interest in this case is confined to the question of *past* damages.

Outside of the electric lighting field the decision is one of supreme interest.

The contract by which the Bell Company obtained control of the Edison microphone patents restrained the Bell Company from engaging in the telegraph business.

Within the present year this contract will have expired, leaving the Long Distance Telephone Company free to engage in the telegraph business. The injurious effect of this move upon the Western Union business cannot be easily computed, and this company may be injured more by the decision than the Bell Company itself.

However, monopoly in the telephone business, as in the electric lighting business, is broken forever, and the next year or two will witness a complete change in the situation.

The next annual report of the G. E. Company will now undergo another revision, and $4,000,000 more will be taken off the item of patent assets—if the directors are honest.

A CORRECTION.

In the tabular matter entitled "Transactions in Local Stocks and Bonds" unintentional injustice was done to two local companies, the Rutland Electric Light Company and the Portland G. E. Company, by a slight error in the types. By the misplacement of reference marks both these companies were made to appear as receivership properties. This was not correct, of course, and as everyone in the trade knows, the credit of these companies is very good indeed. We regret the error, but do not believe either concern could be injured by it.

THE DAY OF JUDGMENT POSTPONED.

John Randolph of Roanoke was the first, we believe, to enunciate the truism that a corporation has no body to be kicked, no soul to be damned.

It is evident that the G. E. Corporation has enough individual responsibility left to desire, like the rest of us, to postpone the day of judgment as long as possible.

The New York Stock Exchange having passed a resolution that all companies having listed stock should issue their annual report at least two weeks in advance of the annual meeting, the G. E. directors at once decided that the annual meeting of this company, which should be held early in April, be postponed to May 14, thus giving all the time possible for the manipulation of the shares on the market.

Go slow, Mr. Charles H. Coster and Messrs. Board of Directors—the day of judgment may be postponed, but it cannot be finally averted.

You will yet answer for your connection with the greatest swindle of this decade.

WISDOM FROM THE FOUNTAIN HEAD.

Pudd'nhead's View of the Situation.

(From the Electrical World, March 2.)

While the G. E. Company has been knocked out in several important instances, its position has been strengthened in other directions by favorable decisions equally as important. Among other things, the company won this week at Cleveland, Ohio, the suit of the Edison Electric Light Company against the Universal Electric Company to enjoin the manufacture of incandescent lamps. The decision is understood to cover very broad principles and to be of great value to the General Electric Company.

$$\text{G. E.} = \frac{100}{10}$$

Municipal Ownership of Niagara Power Distribution for Buffalo.

BY FRANK C. PERKINS, M. E.

A number of resolutions have been passed by the various business associations and societies of the city of Buffalo, and have been submitted to the Street Committee, who have the subject of the Niagara Electric Power Transmission franchise under consideration. Some of the associations recommend that the city of Buffalo contract for the power either at the city limits or on the lands of the Niagara Power Company, and transmit and distribute the electric power at cost to the consumers in the city of Buffalo. Other societies are strongly opposed to this plan, and recommend that a franchise be granted to the Niagara Falls Power Company with the necessary restrictions to guard the interests of the city.

Whether the decision is finally made in favor of municipal ownership or not will be dependent largely upon the final attitude of the power company: 1st, In reference to a time limit of franchise, the power company desiring a 35 to 40 year limit, while many members of the associations consider a short period to be best for the city's interests; 2d, The naming of a maximum price for electric horse-power per year delivered in Buffalo, the power company holding that it is impossible to name a maximum price, while the members of some of the societies state that a maximum price is absolutely necessary in order to insure cheap power for Buffalo.

In case the power company should concede the short time limit and name a maximum price, the indications are that the franchise would be granted with few other restrictions as those two points seem to be the subjects of discussion.

In case the power company holds strictly to the conditions as given in the statement below, absolutely refusing a short-time period and the naming of a maximum period, then the indications at present are that there is likely to be a more serious consideration on the part of the city of the desirability of taking the power at the city limits or at the Niagara plant and making the distribution independent of the power company.

The question of municipal ownership is one that should be looked into with great care. 1st, As to the success of such an enterprise. Can it be accomplished? The visiting of from 40 to 50 central stations in Italy, Switzerland, Germany, Austria, France and Great Britain, for both electric lighting and power distribution, convinced me that municipal ownership, if properly looked after, is a success, as many of these stations were giving excellent satisfaction, and were owned and controlled by the city.

Whether it is for the best interests of a city in this country is a question yet to be decided. There is no doubt, if the best management is secured—if it can be successfully divorced from politics and there are no pockets to be filled—municipal ownership can be made a success in this country. The people are beginning to wake up, and the methods practised in the past in New York City and some other large cities are being repudiated, and it is hoped will soon be abolished forever.

It is a question of vital importance whether municipal ownership is advisable at this time for the Niagara power transmission. In regard to the discussion a year ago, it might have been favorable for municipal ownership in regard to arc lighting, because in that case no experimenting was necessary. Hundreds of arc plants are in operation. The lighting of the city with arc lights was, therefore, no more of an experiment than the building of a schoolhouse. If such an arc plant had been built during the past year as was contemplated, it would now be furnishing 2,000 arc lights at a considerable reduction from the present price. In addition, after the Carnival had brought out what motors, etc., were best adapted for the Niagara power, the city could contract for 2,000 or 3,000 H. P., and belt the motors to the arc light machines according to the suggestions of Prof. Forbes, holding the the engines in reserve for an emergency, thus receiving their lighting for a very low figure. Such a steam plant would be necessary for a reserve, but would be adequate for a lighting plant three or four times its capacity.

It is, however, a serious question whether it is advisable now to take the distribution of power in the city of Buffalo off from the power company's hands, as there is still a great deal of experimental work to be done. Can the city do such experimental work as well or as economically as a corporation? Would it not tend to make the power company lose interest in the city distribution? Would it not tend to make the power company shirk responsibility? Would not the company naturally say: "Well, here is the power at the city limits, do with it as you please," and if mistakes occurred, which would be very liable to happen with the first apparatus installed, if a short-circuit was made which damaged the dynamos at the Falls, the city would be blamed and a lawsuit for damages might follow.

A discussion of this problem might be a matter of interest to the readers of ELECTRICITY, as the opinion of some engineers generally opposed to municipal ownership might be favorable in such a special case as this one, while other engineers, usually in favor of municipal ownership, might consider this an extra-hazardous undertaking on the part of a city. The opinions of Mr. Nelson W. Perry, of ELECTRICITY's editorial staff, would be very valuable, and would be appreciated by the many readers who are specially interested in this subject.

The three propositions of the power company for the sale of 10,000 H. P. to the city of Buffalo, delivered on the lands of the company at Niagara, are especially interesting, involving as they do the question which, if any, would be best for such an undertaking. The following is the statement by the Niagara Falls Power Company of its position in regard to its power for use in Buffalo in response to the request made at the Common Council meeting February 7, 1895:

THE PENDING APPLICATION.

This application has been made by the Niagara Falls Power Company as a necessary basis for its decision as to transmitting to and distributing in Buffalo 10,000 H. P. generated in its power-house at Niagara Falls. To be ready to do this will involve the extension of the present wheelpit by at least 140 feet, and the installation of three 5,000 H. P. turbines and three 5,000 H. P. dynamos in addition to those already ordered and partly installed (one being a reserve); also the building of transformers, transmission lines and a distributing system. We are advised that such extension of wheelpit and the necessary hydraulic and electrical installation can be made within eight months from the time the order is given for the work and plant. Before the order is given it is necessary, therefore, for the company to know, and at an early day, what action the city of Buffalo will take in regard to a franchise.

The Power Company has found that it cannot economically transmit to Buffalo less than 10,000 H. P., and it cannot consider the transmission of any less amount. If a proper franchise be granted, the company is prepared to institute the arrangements necessary to effect the proposed transmission and distribution of 10,000 electrical horse-power generated at Niagara.

While the company recognizes the propriety of provisions for the protection of property and the public safety, there have been suggested some restrictions which, if incorporated in the franchise, will absolutely prevent its acceptance by the company.

1. The company cannot accept a time limit less than the term of its bonds; such a restriction would deprive the company of any proper or usual basis for estimating the propriety, security or extent of its proposed investment; and

2. The company cannot consent to the fixing of a maximum or other price for power within the city.

The price must be left as a matter of negotiation in each instance between the company and the taker of the power, who will find adequate protection in the fact that unless the electrical power can be used at a cost below that of steam power it will not be used. The company will be prepared to sell, and can sell, power in Buffalo to those who wish to buy it only because they find it more economical than any other power.

MUNICIPAL CONTROL.

It has been suggested that the city purchase the power from the company at Niagara.

The company is now ready to execute a contract in either one of three forms for the sale to the city of Buffalo of 10,000 H. P., deliverable on the lands of the company at Niagara, upon the following terms and at the following prices:

10,000 H. P. undeveloped on lands of the company at Niagara, at $10 per horse-power per annum, twenty-four hour power; the city of Buffalo to make its own wheelpits and side tunnels and to put in its own wheels. The necessary water, the inlets and the necessary discharge space in the completed tunnel of the company are now ready to produce this power.

This form of contract is of public record at Lockport with the Niagara Falls Paper Company, by whom this form of power has been in satisfactory use for over one year, showing that interruptions from ice or other causes are not to be feared; or

10,000 H. P. developed on the shaft of turbines furnished by the company on the company's lands at Niagara, at $18 per horse-power per annum, twenty-four hour power, so to be delivered within six months from the execution of the contract; or

10,000 H. P. electrical alternating current, at a voltage of 2,000 as it comes from the company's generators at the power-house, twenty four hour power, at *$18 per horse-power* per annum, to be delivered within eight months from the execution of the contract.

In the event of the city making a contract for power in either of the above forms, the company will place at the disposal of the city all the data which it has gathered in a five years' study of the problems of transmission, and will arrange for a satisfactory use by the city rights of way between Niagara Falls and Buffalo which the company has acquired. These rights of way are three in number and are practically complete.

The company cannot name a price for electrical power transmitted to the Buffalo city line, as in the question of transmission are involved the uncertainties of the losses and cost of operation and maintenance.

PRICE OF ELECTRICAL POWER AT NIAGARA.

The company has made a contract with a large electrical power user for not less than $20,000 per annum for 1,000 electrical horse-power delivered on the company's land.

As this statement has been called in question, the company now offers to submit this contract to the inspection of the Mayor of the city of Buffalo.

COST OF STEAM-POWER IN BUFFALO.

Referring to the tabulated statement said to have been prepared by Mr. Richard Hammond, and recently published in the Buffalo *Courier*, showing the cost of 1,000 H. P. ten hours per day to be $21 per horse-power per annum, the company is prepared to prove that for the city of Buffalo and under the conditions assumed in that statement the annual cost of such ten-hour power is not less than $32 per horse-power per annum.

If there were any plants existing under the same conditions and of the other sizes mentioned in the publication, the discrepancy between the figures estimated for the larger units and the actual figures would be even greater.

With a determination to avoid all arbitrary estimates, consideration has been given to actual facts and actual conditions in the cities hereafter mentioned, and the following figures are submitted, which may be regarded as indisputable:

	Per H.P. per ann.
A recent test by a disinterested expert of the cost of steam power, ranging over a period of eighteen months, in a Buffalo plant using considerably over 1,000 H.P. under excellent conditions as to economy, shows the annual cost of such eleven-hour power to be	$32.70
At the Buffalo City Water Works with engine capacity of 3,600 H. P., the average cost of all the engines in use for the years 1893 and 1894, as stated by their engineer, for over 2,000 H. P. is	77.55
Mr. Knapp estimates that for 1895 the cost of 3,000 H. P. will be over	60.00
This is pump horse-power and the average efficiency of the engines having been found to be 80 per cent., the average cost of the steam horse-power of the pumping engines for the years 1893 and 1894 is	62.04
In Milwaukee, Wis., as the result of a year's work at the North Point plant of the city's water works, with steam pumping engines of 500 H. P. (a plant which Prof. R. H. Thurston, the recognized Ameri-	

can authority on the cost of steam power, pronounces one of the most economical steam plants in existence), a careful examination shows the cost of pump horse-power to be..	$75.83
And for steam-power to be	68.25
And this is exclusive of any allowance for insurance and taxes.	
In Urban & Company's flouring mill in Buffalo, a 400 H. P. plant operating twenty-four hour power, a recent expert test covering the year 1894 shows the cost of this twenty-four hour power to be not less than	45.00

Mr. Huntley, the General Manager of the General Electric Company of Buffalo, states that it is safe to say that in nearly every factory in the city the cost of steam power is not less than $45.00 to $60.00.

If the city does not desire to purchase power at Niagara as above suggested, then, within the limits and to the extent above stated, but not otherwise, the Niagara Falls Power Company respectfully renews its application for a franchise in the city of Buffalo.

It has generally been considered that the figures of Dr. Chas. Emery, as given in his paper before the American Institute of Electrical Engineers, were correct and fully within the safe limit for actual practice. Dr. Emery's figures were about $22 per H. P. per annum with coal at $2.00 per ton. In Buffalo the cost of coal is $1.80 per ton.

The Monocyclic System.

Discussion of Dr. Bell's Paper at the Cleveland Convention.

Mr. Kelly—I suppose I can honestly begin by paying a tribute to the ingenuity of the devisers of the system; but it is scarcely necessary, because we all know what they can do—how ingenious they have already proved themselves. I cannot help feeling, however, that in this case their ingenuity has been somewhat misapplied. The most serious fault with the system is that it did not come soon enough. If it had come before the polyphase systems had been worked out, perhaps we would not have needed any polyphase system, but coming when it does, it seems to me a step backward. In the first place, the generator, as Dr. Bell explained, is substantially a single-phase generator. Now in any given generator, it is not possible to get the same output and regulation when worked single phase as when worked two phase. Dr. Bell seemed to think that the two-phase was in trouble because of the difficulty of balancing the two circuits. I am more familiar with that system than any other, and my own reason for preferring it is because the regulation is better than if the work was thrown on one circuit. We have found that there is no more difficulty in balancing than in the common three-wire system. When it comes to the lines, I suppose it is in this point that the chief advantage of the monocyclic system is supposed to lie; but the system requires at least three wires and any polyphase system does not require more. Where lights only, and not power, are required, it only needs two; in practice that is all that any polyphase does. In any district where light only is required, you need only run a pair of wires, so that in this respect there does not seem to be any gain in the monocyclic system. The cost for copper is, at the least, according to Dr. Bell's diagram, higher than it is with the plain single phase, while the cost of copper in the two-phase three-wire system is very materially reduced. In the circular distributed I see it is stated that where power only is to be transmitted by means of the monocyclic system, the third wire is of the same section as the other two, making an addition of 50 per cent., but if the system is so working that this third wire is really a power wire, conveying energy, then there is not only this additional cost but the percentage of drop in the circuits is increased beyond that in the single-phase system.

Dr. Bell has raised the question as to the periodicity at which motors can be worked. Now there are undoubtedly great advantages in low periodicity in cases of long distance transmission; but one of them is not the possibility of operating motors. There is no difficulty in making polyphase motors of 16,000 alternations which will have high efficiency and start with large torque. As to the efficiency of the motor in the monocyclic system, there is nothing to be said against it, because the motor is substantially a polyphase motor, and whatever the polyphase motor will do of course the monocyclic will do.

Mr. Steinmetz—I am very much honored by being able to speak before such an Association as this, and may say that I have heard with very great interest Dr. Bell's interesting paper, and with much greater interest, Mr. Kelly's remarks. I can, however, not quite agree with his statement that the single-phase alternating-current system is antiquated and superseded by the polyphase system, and that therefore the monocyclic system is behind the times. The polyphase system has been before us now for nearly ten years. It made its appearance shortly after the single-phase system, and at a certain time after the Frankfort Exhibition, when our electricians came back from Europe and talked excitedly of what they had seen. Everybody seemed to think that the single phase system would soon disappear altogether. Nevertheless, we have now thousands of single-phase stations running, while the polyphase system is only just beginning to be used in special cases. Therefore I feel confident that the polyphase system will never be able to supersede the well-known single-phase system of old, but find that it possesses a limited application, although being very valuable at the proper place. The monocyclic system is entirely single-phase; that is to say, the total flow of energy issuing from the generator passes through zero and is fluctuating, while the polyphase systems share with the continuous system the common feature that the flow of energy is not zero, but more or less constant. E. M. F.'S of different phases, or currents of different phases, do not constitute the polyphase system; for in the ordinary single-phase system if a reduction coil is connected in series to incandescent lamps you get E. M. F.'s displaced from each other by 90 degrees; that is quarter-phase E. M. F.; and in a loaded transformer and in a transformer running light the currents are displaced in phase. In neither case, however, do we speak of a polyphase system. The polyphase system is indicated when both E. M. F.'s as well as currents differ in phase from each other.

Now with regard to the statement of Mr. Kelly that the output of a polyphase machine is larger than that of a single-phase machine, that is a common mistake, repeated now for years. It means that on the polyphase armature more wire can be put than on the single-phase armature. However, the output of an alternator is not limited by the amount of wire you can put on the armature, but by the armature reaction, or rather by that amount of armature reaction which you can take care of by the field; and in a single-phase machine you can by compounding take care of a very great armature reaction which you cannot take care of in the polyphase machine, where small armature reaction causes unbalancing of the circuit, in consequence of which the output of a polyphaser is less than that of a single phaser of the same size and speed, or at least not greater.

Professor Thomson—The paper of Dr. Bell was so full and so clear that it leaves very little for me to say, except that I can express my agreement with the statements of the paper, and that furthermore, after due consideration, I think Mr. Steinmetz has the right of it. He has given an enormous amount of time and attention and close study to the question of polyphase, single-phase and other systems, and has originated a number of remarkable combinations, one of which is the monocyclic system. I think the system undoubtedly accomplishes all that has been stated by Dr. Bell to be its advantages.

Mr. Scott—I have been, and I am sure all of you have been, very much interested in the presentation which has been made by Dr. Bell of the monocyclic system. We can take it, I think, as a carrying out of the remark that I made in an Association a year-and-a-half ago, that when we have an alternating polyphase system we have something that we can do something with. It is flexible—we can twist it about, we can make a two phase and three-phase system, and now a monocyclic system, variations of the polyphase system, and go from one to another and get the different advantages which any one of these may present for different kinds of work.

We have had the characteristics and advantages and merits of this system pointed out. It may be well, it seems to me, to bring forward some of the questions which arise with respect to the points which have been brought out so that they may be answered now, and that we may determine the relation of this system to the other systems. To those who are not immediately and technically familiar with the subject there is apt to be a sort of haziness about it. We hear first about the two-phase and then about the three-phase system, as if they were entirely new and different. As a matter of fact there is no fundamental difference between the two. Then we have a monocyclic system. What relation does it bear to the other systems? Is it radically and entirely new? Does this euphonious name mean something which is a departure from what has gone before, or is it a modification, and if so, of what is it a modification?

Starting with the source, the generator itself is just now somewhat in doubt. The single-phase generator is best, because it regulates better and has a better output. The polyphase generator, it is also stated, regulates well and has a good output, and without carrying that further, we can all be satisfied by taking our choice. We will consider a few points made with respect to the transmission circuit. There are one or two statements of Dr. Bell's which can either be called in question or certainly a little modification made to them. A two-phase four-wire system, which he has given as the third figure, he has considered as the correspondent of the alternating two-wire circuit only, and has not considered it applicable to use in a three-wire connection, in which the amount of copper is so much less. The reason of this was the added complication of running two three wire circuits. That might be true if the area to be covered were quite small, but as central stations usually run, the lines are carried out in different directions. In alternating stations there are anywhere from three or four to a dozen or several dozen feeding circuits running in different directions and supplying different territories. It is just as easy to divide these up into three-wire circuits for lighting, as the different parts of the city to be supplied or the districts are separated, as it would be if all of the circuits were of the same phase. If, therefore, the distribution can be carried on by the three-wire plan, the cost of copper here would be materially reduced and be made equal to that of the three-wire single-phase system. Considering the two phase three-wire system, the figure 145.5 was stated as the relative amount of copper used, and that a possible reduction to 72.5 if the extreme E. M. F. can be increased above that for the first figure upon the diagram, which is for the two-wire single-phase system. The assumption upon which all these figures have evidently been made is that there has to be a definite E. M. F. for the carrying of lamps. If that is to be carried through the various diagrams, then the 72.5 is a proper figure. If, on the other hand, a limited voltage is the consideration to be met, we have in the ordinary three-wire circuit twice the E. M. F. of the single-phase circuit. If the same be applied to the two-phase three-wire circuits then the amount of copper would not be 72.8, but one half, or about 36, so that the figure 145.5 in connection with that diagram is not in accordance with the assumption of the E. M. F. being controlled by the lamps in circuit; and if the highest E. M. F. allowed is that of the three-wire circuit, then the additional figure for the weight of copper for the two phase three-wire system should be 36 in comparison with the other figures.

Another point in connection with the lines is the unbalancing of circuits. It was stated that the two-phase three-wire circuit is one which is liable to unbalancing because of the reaction of one circuit upon another. While this is true in certain cases, in ordinary working it is one which would be met with but seldom. The next point in the system after going through our transmission circuits is the transformer. The transformers for transforming a given amount of energy for lighting or for power by the two-phase system, in which one transformer is placed on each of the two phases, is the same as that for the single-phase system. For the three-phase system, in which transformers are connected across each pair of mains, the converter capacity is the same; that is to say, if we have six transformers we may connect them in parallel across the single-phase circuit, or we may connect them in two sets of three each on a two-phase system, or we may divide them into three groups of two each on the three-phase circuits, and each transformer will have the same individual capacity in each position. When, however, these transformers are connected as in the diagram illustrating the monocyclic two-wire system, then these transformers, as has already been pointed out, do not operate in their ordinary way. Although the E. M. F. upon them may be normal, the currents flowing through the transformers differ from those in ordinary cases. They are not in phase with the E. M. F. upon the transformers, and the output of the transformers is reduced by a very appreciable amount—if I am correct in my present recollections, some 16 per cent. Thus transformers of about one-sixth greater capacity would be required for operating a motor under this system above that which would be required if the same motor were operated by two-phase or three-phase systems.

The transformers in the monocyclic three-wire system also seem to require an excess capacity. If the large transformer in that diagram is the one which supplies the lights and operates the motor when the motor is doing something, then the little auxiliary or teaser transformer is one which is useful only at the start and contributes nothing to the regular working of the motor according to the assumptions which have been made. This transformer, therefore, is an additional piece of apparatus which must be provided in the system.

With regard to the motor itself, I observe that the motor in the monocyclic two wire system is a three-phase motor and nothing else. I understand that the motors used are the standard three wire motors, and the motor itself does not know where it is getting its supply, whether from a regular three-phase system or a two wire monocyclic system. The transformers for this motor on the three-wire three-phase system would naturally be the three. We seem here to have cut off a part of this system by cutting out one of the transformers. We are not keeping the symmetrical arrangement now, but are supplying the motor by but two transformers, leading to the result to which I have just called attention, that is, a larger transformer capacity. The reversing of the secondary coil of one of the transformers, if I understand the connections and arrangement, would be obviated and the transformer would be connected directly without this crossing if the primaries of these transformers were directly connected to three-phase mains. Suppose we have a system, then, with three-phase mains with three transformers connected, feeding respectively the three circuits of the motor. Now we cut out one of these transformers, but our motor will still run, but without the same efficient performance of the transformers. If we change the relation of the middle wire at the dynamo, or change the voltage of this wire, we can do so in such a proportion that the phases of the two primary circuits will not have their former relation, will not be 120 degrees apart, but 60 degrees apart. In this case it becomes necessary to reverse one of the secondaries in order to obtain two currents 120 degrees apart for operating the motor. If, therefore, the teaser coil were wound with a different number of turns to give a higher E. M. F. we might have a three-phase generator supplying directly three-phase mains. What this seems to be, then, is really the elements of the three phase system distorted somewhat by changing the E. M. F. on the middle or teaser wire and reversing the secondary of one of the transformers and leaving out the third transformer. So much for the motor which operates from the two-wire monocyclic system.

The motor on the three-wire system seems to have somewhat different relations. This is not a three-phase motor, but, I take it, is a two-phase motor, and it is rather interesting.

Dr. Bell—It is a three-phase—the same motor as the other.

Mr. Scott—Very good; but on the diagrams I have seen of this monocyclic system I have taken it as a two-phase motor, the two windings being given in the diagram as two coils placed at right angles to one another. The very reason for bringing up this discussion and making it so full at this time is to get a correct understanding of these motors. The understanding which I got from the diagrams and explanations which I have seen of the system seems to me to represent a two-phase motor, one of the circuits being wound through directly similar to the monocyclic generator. This motor has been pointed out—I do not remember whether in the paper Dr. Bell has just read or not—as similar to the monocyclic generator, which is stated to be a single-phase machine wound with one winding straight through from one end to the other, with this little auxiliary or teaser coil connected between the middle of that coil and a third terminal. If this be the case, then it seems to me that this motor is either a single-phase motor or a two-phase motor. The explanation given of the operation of this motor has not been very complete to-day. If I make a mistake in drawing on other sources of information in regard to it I hope I will be corrected.

This motor I have taken to be a single-phase motor when running at speed, but essentially a two-phase motor which is supplied by the three wires that are operated by two transformers which have E. M. F.'s at right angles, or the 90 degree relation of the two-phase motor. We are supplying, then, to this motor the output of two converters which are operated at a difference of 90 degrees. All the circuits of the motor are active while the motor is coming up to speed. One of the windings on the motor is somewhat different from that of the windings on the transformer. It is not exactly proportioned in both of its circuits to the E. M. F. supplied, so that when run at speed one of the circuits does all the work. It is very much as if two transformers are connected in parallel, one giving 100 volts and the other 99 volts. If we put a load on the two transformers connected in multiple until the E. M. F. drops to 99 volts, then one of the transformers would be carrying all the load and the other nothing. The motor described here is the same motor, if I understand it correctly, as is described in the patents granted to Mr. Steinmetz. Then it seems to me that this motor is very similar to a sort of lopsided two-phase motor, stronger on one side than the other. The two circuits operate with fair effect to bring the machine up to speed, and then one of the circuits takes all the load and the other has but little to do. The motor in running at full speed and doing its regular work operates as a single-phase motor. A single-phase induction motor will not carry the same load that the two phase induction motor will. Anyone who has operated two phase induction motors knows that one circuit may be cut out and the machine will continue to run, but it will not carry the same load as before. If that be true, and the information upon which I understand the connection of this motor be true, then this monocyclic motor seems to be a rather decrepit two phase motor

There is one point to which attention was called by my able friend, Mr. Steinmetz, to which I take exception. That is his definition of a polyphase system or a polyphase motor. He was pleased to say that difference of phase in E. M. F. with no difference in current does not constitute a polyphase system, and he pointed out that if a coil and a lamp be placed in series, the E. M. F measured directly across the lamp and the E. M F. measured directly across the coil would not be in phase with one another, but would occur at different times. So also if a coil and a lamp be placed in multiple so that the same E. M. F. is on the terminals of both, then the currents are not of the same phase But he held that neither of these would constitute a polyphase system, because the flow of energy was not constant. A constant flow of energy may be taken as a definition of a polyphase system, so might difference of E. M. F. or difference of currents. As I understand a polyphase system, I do not mean that the E. M. F. at one part of the circuit may be one thing and at another part somewhere else another thing; either at a great distance or connected with a different piece of apparatus, that would not necessarily constitute a multiphase system; but if the two different elements with difference of phase cause the operation of that apparatus, then we have the essence of a polyphase system. If we have a motor and wind its circuits in such a way that the circuits shall differ in capacity or self-induction if the currents in the different circuits differ in phase, and owing to this the apparatus operates and the motor runs, then we have something which should be legitimately considered as polyphase apparatus. We have an apparatus which operates due to the difference of phases, or to too many phases, and in the polyphase motors that is the characteristic element. The element which causes rotation, the fundamental element, seems to be the shifting of the magnetic field in the apparatus. It is not fundamentally essential to the operation of such an apparatus that the currents give equal energy to the apparatus at all times, but that they be supplied in such a way as to give the shifting field which will cause the rotation and running of the apparatus. I would therefore call a multiphase machine one which has in it a shifting magnetic field of many phases or currents producing these magnetic fields, rather than one having a flow of energy to the apparatus.

The power wire operating in the monocyclic three-wire system is said to be a powerless wire. This wire is for the purpose of operating the motor while it is coming up to speed. The two great problems in an alternating current motor are the bringing of the motor up to speed and the keeping of it there. These are two different problems, and different methods are devised for effecting the two different results; very often the elements which contribute to one detract from the effectiveness of the other. The power wire, if I am right in understanding this motor, does not necessarily supply power to the motor at the time when the motor is running at full speed, but it contributes to the power which is required for bringing the motor up to speed, and would continue to deliver power to the motor instead of lying idle and resulting in so much idle copper in our system if the motor were a complete and symmetrical motor instead of one which has possibly been made defective to meet the requirements of this system

Dr. Bell—The first question raised may be granted, that the monocyclic system is a modification of something. Is it now to be considered as a single-phase or two-phase system, or a polyphase system of some sort? I think that question was clearly answered by Mr. Steinmetz when he pointed out that you must consider as a polyphase system one in which the energy remains constant—the common characteristic of all polyphase systems whether evenly balanced or unbalanced. In the monocyclic system we have three currents substantially in phase with each other, and the told energy passes through zero. I fail to see how the widest possible extension of the definition of a polyphase machine could be made fairly to include it. The most that could be said would be that there might be a limiting case in which the unbalancing of a polyphase system might go on until the total energy would actually pass through zero. If that is so, it might serve equally well as a limiting case for either the single-phase or the polyphase system. It is certain that the monocyclic in its operation suggests a polyphase system in the character of the currents which flow through it and in the distribution of the energy. It is peculiarly single-phase in its character. I was interested in Mr. Scott's remarks on the subject of the four-wire connection of the two-phase, and in the second place, the three-wire connection of the two-phase system. Now, with a four-wire connection, it is of course possible to use the Edison three-wire system on each branch if one so desires; but in order to do so, and to run motors at the same time, one must interlink the two three-wire systems—in other words, you must have two three-wire systems, each system being approximately balanced as to itself, and each three-wire system balanced as respects the other three-wire system occupying the same territory. They must be interlinked for motor service, and that is the reason which, I maintain, bars out the two-phase four-wire system from employing the Edison three-wire connection, just as it must bar out in the same way, and even more effectively, the three-phase system from operating on each of its three phases an Edison three-wire system. It makes a complication of circuits for general distribution which would be perfectly intolerable—two three-wire circuits in the same territory, and each balanced with respect to the other; it would be something better imagined than described. In certain cases for lights only it may be applied, because you are at liberty to scatter your circuits, but even then it would require more or less balancing of the two systems, else you get into trouble with one side of the machine having a greater load than the other, which causes a difference in drop which cannot be compensated by compounding. With the two-phase three-wire system Mr. Scott's point was well taken on the question of maximum voltage. However, if you are dealing with the maximum permissible on the transmission line, where the thing to be considered is not the maximum on the distributing system to translating devices but the maximum permissible on the whole system—if you confine yourself to that, you will find that combining the two-phase into three wires requires excessive copper. If you confine yourself to the secondary system alone it will be possible to permit the same maximum voltage as on the straight Edison three-wire, and I should say that the same rule would apply to the reduction of copper in the three-phase three-wire system or any other systems in varying degree according to their character.

As regards the question of unbalancing, I think I stated with a fair degree of distinctness that with any polyphase system, though unbalancing may occur, and occur in a serious degree, I do not believe it would be a common occurrence. I think I specifically included the polyphase systems in general.

With regard to the question of the reduced capacity of transformers operating on three-phase or monocyclic systems: As a matter of fact there are three plans of working, we will say, with a three-phase system as regards its transformers; in the first place we may have a composite transformer, including all three legs of the circuits, which has been used with very fair results. Next we may use three transformers, or finally only two transformers. Sometimes it is more convenient to use three, and sometimes two. We must remember that there are not to be had an infinite number of sizes of transformers, nor an infinite number of sizes of motors. The consequence is it is sometimes a difficult matter to find transformers which will exactly fit a given horse-power of motor, and the loss of capacity which is thus met in furnishing transformers too large for the motors (because we must be sure to have them large enough) may easily amount to 10 or 15 per cent. either with two or three phases, and unless special transformers are made to fit the motors we are liable thus to require an increased total capacity of transformers as well on two-phase as on three-phase systems. With the three-transformer connection for the three-phase circuit we have one very material advantage which perhaps makes it worth while to employ it in many cases, and that is if one of the transformers for any reason is crippled we can operate at least two-thirds of the output with the remaining two, whereas on the two phase system if one transformer gives out the motor is crippled, either by overloading and stopping absolutely or able to run at half output as a single-phase motor, but in no case starting until the transformer is fixed. If two transformers are used, the statement has been made that the loss in output in connecting three-phase transformers is about 16 per cent. I would like to see experimental evidence brought up in this case. We have been informed in many well written technical articles that the output of the polyphase machine was thus and so in connection with a single-phase machine, and we know that the facts do not fully bear out the theory. We are now given similar information in regard to the transformers. While I am not prepared to dispute the fact without having experimented on it, I would like to see some evidence that the difference in output rises to any practical magnitude.

As regards the teaser transformer, I think we may consider the secondary transformer on the monocyclic three-wire system as practically part of the power wire. It needs to be of small size and furnishes only a small amount of energy. With that connection the one transformer furnishes the power wire for the whole three-wire system. It is not a part of each motor, simply a part of a power wire, and as such it may be taken as a part of the installation belonging to the three-wire system. The single small transformer in the system furnishes the entire power wire for the whole system.

As regards the motor on the monocyclic two-wire system, it is correct in a sense to say that the motor does not know whether it is on a three-phase circuit or a monocyclic. As regards its operation, it does not know—that is, as regards the direction of the E. M. F.'s in it. It is a matter of perfect indifference which system it is on; but as regards the character of the currents and their direction, if the motor possessed an ammeter to put in its own coils it would find there was a very large difference in the distribution of currents. As regards its magnetic qualities it would not matter, although the actual distribution of the current is widely changed. We have in the monocyclic induction motor a motor which in its operative qualities is like a polyphase motor. Nevertheless, the distribution of currents in it, although resulting in a perfectly symmetrical production of motive power, is something that you cannot find in any polyphase motor. It depends on the particular action used in the monocyclic system. It has essentially a single-phase current, although its effect as regards magnetism is closely similar to that of the true polyphase motor.

As regards the motor on the monocyclic three-wire system, I was much pleased with the ingenuity with which Mr. Scott constructed a large, able-bodied and well-dressed man of straw for the purpose of knocking the gentleman down and jumping on him with both feet. The motor is not a two-phase motor of any kind. It is an ordinary induction motor, such as is used indifferently on three-phase or monocyclic systems. Doubtless, from the experience of the speaker, he deeply realized how bad a bad two-phase motor could be. The winding of the monocyclic motor is in every respect similar to that of the three-phase motor. There is a possibility, and sometimes a great convenience, in being able to work a monocyclic generator as a synchronous motor. Used in such a way it works during its operation like any other synchronous motor. It is a possibility which is sometimes very convenient. The motor starts itself, and the teaser coil, when the motor is up to speed, produces no effect on the rest of the system if the motor is properly designed with reference to suppressing the E. M. F. of the teaser circuit. In the monocyclic three-wire system we have in the first place a three-phase motor structure, but operating on a monocyclic three-wire and teaser circuit, with the properties and distribution of currents—or electrical character—of the single-phase system. The actual details of operation in a monocyclic motor are somewhat complicated. Substantially we have a structure which in all its characteristics is only proper to be operated on the monocyclic or three-phase circuits. The currents which flow through it, however, are not three-phase currents, the E. M. F.'s being 120 degrees apart. The currents are substantially in phase, but the magnetism produced is so distributed as to give a perfectly symmetrical torque on the motor just as though it were run upon a polyphase circuit—a point which, I think, justifies me in the remark I made at the beginning, that the monocyclic system is to be regarded not altogether as a modified and glorified single-phase, nor again as a decrepit and disreputable polyphase system, but rather as in a class by itself.

The discussion on Dr. Bell's paper, which was broken by other business and adjournment on Wednesday, was resumed at Thursday morning's session, as follows:

W. R. Gardener, of Pittsfield—I am very much interested in this question of multiphase apparatus, and after hearing the paper read yesterday, and the arguments which followed it, I am not quite certain about it. I do not pretend to know anything about polyphase or multiphase systems, or teasers, or anything of that kind, but I do know when I have something in my station that gives me perfect satisfaction. I know that I have got something in my station that satisfies my requirements as central station man. We are operating a two-phase machine, and have been for over a year and a half. The first work required of the two-phase machine was to furnish fifteen horse-power a mile and a half from our station over an existing circuit. We ran an extra wire, and from that circuit are furnishing incandescent lights to stores and dwellings and also this fifteen horse-power. Later on a fire occurred in a mill and their engine was destroyed. We put in two motors of twenty horse power each, and furnish power on this circuit, giving perfect satisfaction. Our business increased, and we were obliged to put in larger machines, and to-day we are furnishing power, incandescent and arc lights from this one machine. We are at the present time going to change our station. We have got five alternating-current machines from 750 to 1,500 lights capacity—machines as good to-day as when they were bought—but we cannot afford to run them as long as there is something better. But the items of repairs on ordinary apparatus is enormous, as you know. With these two-phase machines, including the transformers and motors, we have not spent one cent. We are going to take out the five machines referred to and put in one two-phase machine, and instead of our dynamo attendants bobbing from one end of the switchboard to the other and reading five ammeters and voltmeters they will read one. We have not experienced any difficulty on these lines.

Royal E. House.

Royal E. House, who died recently in Bridgeport, Conn., was born in Susquehanna, Pa., in September, 1814. His first patent was numbered 1,200, his latest No. 533,600. Prof. Morse had taken out his earlier patents, but had not built the first electro-magnetic line from Washington to Baltimore when Mr. House conceived the idea of the printing telegraph. He made his first machine for this purpose in 1844 and exhibited it in New York. The system printed its message in Roman letters, and the actual speed attained was fifty words a minute. In 1884 the Morse Company filed a petition for an injunction, claiming an infringement, and to stop House operating a line between New York and Boston. The court decided that there was no infringement. When it was found that by the Morse system the message could be taken by sound the expensive machine of Mr. House went out of use. Mr. House was the inventor of several other instruments used in telegraphy.

Have Opened New Office.

The firm of Metcalfe & Moeller, whose main office is at 348 Ninth avenue, have opened a down town office at 201 Electrical Exchange Building, where orders may be placed for the repair of incandescent lamps, and all business with the concern can be attended to.

THE AMERICAN INSTITUTE.

H. Ward Leonard's Views.

On Wednesday evening, Feb. 27, the American Institute of Electrical Engineers held its 94th meeting at New York and Chicago. The chief feature of this meeting was the reading by Mr. H. Ward Leonard of a paper giving his impressions of electrical engineering developments in France and England which were gained from a recent visit. The paper was one of exceeding interest and drew forth a most animated discussion which was participated in by Messrs. Wolcott, Lieb, Emery, Lloyd, Kennelly, Forney, Hutchinson, Sachs, Houston and others at the New York meeting, and doubtless by quite as many at Chicago, but of the latter meeting no reports are as yet at hand. The following is an abstract of Mr. Leonard's paper:

NOTES ON RECENT ELECTRICAL ENGINEERING DEVELOPMENTS IN FRANCE AND ENGLAND.

As a result of inspecting some of the most interesting of the developments in the field of electrical engineering during a recent trip to France and England, and as a result also of having met many of the engineers responsible for these recent developments, I find it difficult to reach a conclusion as to whether we or our contemporaries across the water are ahead in the electrical engineering race.

Although I have always felt that so-called fundamental patents and the resulting enormous aggregations of capital and engineering talent under one management were a millstone around the neck of our profession, I have never before had the opportunity of seeing positive and unmistakable evidence of it such as this visit abroad showed me.

In the beginning of electric lighting, both arc and incandescent, we led the world from an engineering standpoint, and were years ahead of any other country. But what has been done in this country in the way of a remarkable electrical engineering development since Edison started his first three-wire system at Sunbury, Pa., in July, 1883, and Westinghouse established his alternating system with 1,000-volt primary and 50-volt secondary a few years later, and Sprague started the Richmond electric road. A moment's thought will, I think, make you all realize that the practical development of electrical engineering improvements is almost impossible against the opposition of the gigantic corporations in that field, and that corporations having such a large portion of their capital represented by patents will not wish to see the practical trial of a promising improvement which they do not control, and which may depreciate the value of the methods they control or claim to control. It is just this way that we are losing ground when compared with England and France.

We undoubtedly have the best three-wire central station plants in the world, also the best alternating system converting from 1,000 to 50 volts. But what other kind of central stations have we to point to? Practically none.

We have 500-volt continuous current electric railways galore, and we operate such railways at distances for which 2,000 volts should be used instead of 500, and after investing more money in copper per car than the entire cost of the electrical equipment we still lose twice as much energy as is commercial in the line.

Is there a large electric railway system in this country which as an electrical transmission of power is a credit to our profession? Not one.

In France, and even more in England, one is forcibly impressed by the many kinds of central stations being tried. Many of them may seem almost sure to prove commercially unsuccessful, but who can say which one may not prove the "Sunbury" of an enormous electrical engineering development?

No capital or patents can prevent the slow development of evolution, but I fear that under the existing conditions we shall have to content ourselves with drawing pictures of what might be done, and watch the continued introduction of the three-wire system of 1883, the 1,000 to 50-volt alternating system of about 1887 and the continuous current 500-volt railway system of 1887, while our engineering friends abroad keep trying not only their own ideas, but the ideas of many of us from this side, because they have the necessary encouragement and opportunity to do so while we have not.

MANUFACTURING AND ENGINEERING.

In England there is a multitude of medium size concerns, manufacturing electrical apparatus, and the competition is mainly on ideas, and not the cost of dynamos per kilowatt. It is surprising to find that generators and motors are much cheaper in the United States than in either England or France, notwithstanding their advantages over us as to cheaper raw materials and labor.

STEAM ENGINES.

I believe we are ahead of England and France in the designing of dynamos and engines. Their workmanship leaves nothing to be desired, but giving consideration to amount of material used, efficiency and design, I think we are in advance of them.

One of the most surprising things to me was to see the almost universal use of engines which we would consider had practically no governor. That is, engines using slow acting throttling governors instead of the triumphs of engineering skill which are so common in this country. Not since 1883 have I seen such poor governors as I found generally used abroad in the finest and most recent stations and upon engines which are almost perfection itself as regards manufacture.

THE PARSONS STEAM TURBINE.

The Parsons steam turbine was one of the most interesting things I saw in England. These steam turbines are direct coupled to dynamos, and in sizes of 350 K. W. revolve at 3,000 revolutions per minute, and of course run at higher speed in smaller sizes. The space occupied by a 350 K. W. outfit is over all about 25 feet long, 5 feet wide and including governor about 7 feet high. These turbine plants when running at these high speeds are entirely free from vibration and are not even bolted down, but are supported by three pedestals, one near each end and one at the middle. There are some seven or eight bearings all in line, and a continuous stream of oil is forced through the bearings by a small pump driven by a worm on the main shaft.

Tests by Professors Ewing and Kennedy indicate that this turbine when in perfect condition has an efficiency of one K. W. hour in electrical energy produced by 28 pounds of feed water, the turbine being operated condensing. At Newcastle-on-Tyne I saw a central station of about 25,000 lights operated solely by these steam turbines, and which has been in operation since 1890 and has been earning and declaring dividends ever since it started. An interesting fact as to this Newcastle station is that all the conductors are laid underground and consist of vulcanized rubber cables drawn into cast-iron pipes which are gas and water tight, and through which chemically dried air is forced from the station by a blower.

THE LAVAL STEAM TURBINE.

Before leaving the subject of steam turbines, I will refer to the Laval steam turbine of which I saw a number in the works of the manufacturers, Breguet & Co. of Paris. The number of revolutions of the disk per minute varies from about 30,000 to 15,000 in sizes from 5 to 50 horse-power. The buckets are milled out of a solid disk of steel just inside the periphery, so as to leave a solid band on the circumference. The edges of the buckets are quite sharp. The disk in a case of a 50-horse-power turbine is about ½ inch thick. This disk is mounted on a small steel flexible shaft at a point about ⅓ from one end. At the high speeds in question, a body tends to revolve about an axis through the center of gravity, and since it is impracticable to make the center of gravity absolutely coincident with a straight line joining the bearings, Mr. Laval has used a flexible shaft so that the disk is free to assume such a position as to revolve practically around an axis through the center of gravity, and consequently the disk revolves with perfect smoothness and without any trouble at the bearings at these enormous speeds.

The Laval people claim as high efficiency as that of any steam engine of the same horse-power, and there seems no good reason to doubt their ability to secure such an efficiency which they guarantee fully and specifically.

A careful test made at Stockholm in 1893 showed an efficiency of 20 pounds of water per horse-power hour with steam at 113 pounds initial pressure and used condensing. The weight of this turbine is about 30 pounds per horse-power in a size of about 30-horse-power.

The simplicity of this steam engine, also its theory and practical design, in detail are most beautiful, and it seems likely to become an important factor in the electrical field. What is needed is a generator of electricity directly driven by, or preferably constituting a part of, the revolving disk, and here is food for considerable thought.

ENGLISH CENTRAL STATIONS.

In London I visited several stations of which I will mention two. The first is that of the Metropolitan Electrical Supply Company. This company has an enormous area allotted to it. I found four Parsons steam turbine units of 350 K. W. each, running at 3,000 revolutions per minute. I inquired as to the working of the steam turbines and was informed that they were not able to detect any difference in their coal consumption compared with the compound condensing reciprocating engines formerly in use.

The other London central station I shall refer to is that of the City of London Company. This company supplies the heart of London—that is, the old "City of London"—which is without doubt the best central station territory in the world, on account of the wealthy nature of the customers, the substantial character of the buildings, and especially because of the peculiarly dismal foggy weather in London. While I was there artificial light was required almost as much by day as by night. This central station is beautifully located on the south bank of the Thames, near the center of lighting, and is a fine example of the best that can be done to-day with the alternating system under such conditions. I do not believe it would be possible to find less excuse for the use of the alternating system than in this station, and yet I expect it will pay, for it can hardly fail to earn money under such extraordinarily favorable conditions for lighting.

But I need hardly say that they have no motors except toys, and but few of them; and when I remember that in Chicago 40 per cent. of the connecting load is motors, and that this percentage is rising all the time, it seems evident that the City of London Company is terribly handicapped by the use of the alternating current. However, they have a 2,000-volt primary three-wire secondary, and operate the dynamos all on multiple-arc, which is certainly using the alternating current to the best advantage. Aside from the use of the alternating current under these conditions, it is difficult to say anything in criticism of the central station.

The plant is arranged on the panel system, which Mr. Mordey says originated with him, and which is thoroughly carried out in this station, for each panel or section across the building comprises an independent unit including a boiler, engine, dynamo and switchboard for 500 K. W. The engines are vertical, and direct-coupled to the Mordey alternators. The switchboards are entirely novel in design, being cast-iron pyramids about ten feet high, standing clear from the wall and having all of the conductors inside, with the instruments, etc., mounted on the front face. While very finely finished and ornamental, I could not but think that the vital parts would be more difficult to inspect and repair in case of emergency than in our recent switchboard practice.

One detail of electrical construction in which the foreign practice seems very backward is the rheostats. In this magnificent station in the City of London, for instance, and in many other places, I saw rheostats made by winding german silver wire on a slab of slate, which was then mounted on insulators horizontally on a table, and a slider arranged to move over the surface of the resistance wire itself, which was thoroughly exposed.

Another detail in which we are certainly in advance of foreign practice is our instrument work, for which we must thank Mr. Weston solely. I saw many fine instruments while abroad, but they seemed to be more suited for a physical laboratory than a central station; the substantial, compact, permanent features of the Weston instrument, with its readable scale and dead-beat index, were conspicuous to me by their absence.

FRENCH CENTRAL STATIONS.

In France the most interesting central station I saw was in Paris, where I visited a sub-station designed for a capacity of 30,000 lights. The sub-station was supplied from a distant central station by means of a constant current of 250 amperes, all devices on this current being in series, and the total E. M. F. running as high as 6,000 volts at times.

In the sub-station were rotary transformers, the primary ends of which were series wound motors and all being in series. The secondaries of these rotary transformers as generators fed a five-wire system of conductors, and in multiple-arc with these generators across the five-wire system was a bank of storage batteries. The lamps used were 110 volts; some of the rotary transformers had 110 volt secondaries, four of such secondaries being in series so as to make the five-wire system complete independently of the batteries. Other of the rotary transformers had 440-volt secondaries and fed the outside conductors only. On each rotary transformer was a rheostat, which was in multiple with the series wound field, and which by a step-by-step movement similar to that of the old U. S. automatic regulator, controlled the strength of the series field so as to keep the E. M. F. in the secondary constant, the controlling magnet of the automatic being across the secondary of constant E. M. F.

The storage battery plant was well designed and seemed to be in good order. It was as clumsy and seemed as full of troublesome possibilities as those we have on this side of the water. It had capacity for 8,000 10 C. P. lamps for three hours and cost about $30,000, weighed about 400,000 pounds and occupied a space about 32 x 50 feet. This cost means about $107 per K. W. of output, which seems a pretty high price to pay for a plant to generate electrical energy to-day, especially when it probably has an efficiency at three hours discharge not above 60 per cent. Such a storage battery must be compared in cost with the cost of boilers, engines and dynamos, per kilowatt, which would cost perhaps $50 per K. W., and whose efficiency would be 100 per cent. as compared with the 60 per cent. efficiency of the storage battery, since the storage battery must derive its energy from a steam plant first. The craze for storage batteries as the universal panacea for electrical troubles, which we have all read so much about in connection with European practice, seems to be on the wane if I may judge from the statements of the engineers rather than the storage battery manufacturers, but when we remember that in France and England they do not know what a healthy motor load means, we need not be surprised at the claims of inefficiency for stations which do not use batteries, and hence run their boiler, engine and dynamo for most of the twenty-four hours practically without load.

(*To be continued.*)

To Branch Out and Grow.

A resolution has passed the lower house of the Connecticut Legislature by which the New Haven Electric Light Company is given power to extend into adjacent towns, and the right to establish electric light, heat and power properties, and to obtain control of railways in New Haven and neighborhood. The company, which has a present capital of $400,000, is allowed under the bill to increase to $2,000,000 and issue bonds to half that amount.

The Ansonia Company Revived.

It is said that the recent sale of the plant of the Ansonia Electric Company, at Ansonia, Conn., to Franklin Farrel has resulted in the formation of a new company to carry on the business. The capital stock has been fixed at $56,000, divided into 560 shares of $100 each. The stockholders in the new company are: Franklin Farrel, Thomas Wallace, Jr. (who is the principal and will manage the business), Franklin B. Platt, Louis F. Anschutz, Jonah C. Platt. Fifty shares are held by Thomas Wallace, Jr., as trustee.

SOCIETY NEWS.

New York Electrical Society.

A meeting of the New York Electrical Society will be held at Columbia College, 49th street and Madison avenue, on Thursday, March 7th, at 8 P. M. Mr. Charles S. Bradley will deliver a lecture on "Alternating Currents in their Relation to Power Distribution."

A. I. E. E.

At the regular monthly meeting of the Council, held Feb. 27, it was voted that the General Meeting of the Institute be held at Niagara Falls beginning on June 18.

It is proposed to devote this meeting principally to the question of Power Transmission.

The following associate members were elected: Franklin Robert Anson, Arthur B. Cumner, Joseph Nisbet LeConte, Hermann Loewenherz, Robert C. MacCulloch, Maxwell M. Mayer, J. T. Nyhan, B. C. Paddock, Jr., J. Lloyd Prince, Geo. A. Redman, Bernard Victor Swenson.

The following associate members were transferred to membership: James Wellington Crosby, Hix, Crosby & Co., New York City; E. Randolph Hix, Hix, Crosby & Co., New York City; C. O. C. Billberg, Philadelphia, Pa.; James Hally Craig, Cumner, Craig & Co., Boston, Mass.; Edwin C. Shaw, Akron General Electric Co., Akron, O.

F. R. Upton's Assignment.

Mr. Francis R. Upton has filed an assignment for the benefit of his creditors in the Register's office of Essex County, N. J. The schedule of liabilities foots up $19,315, with contingent liabilities of $58,550. The assets are stated roughly at $20,000, and consist of real estate, promissory notes and a large amount of stock in various manufacturing and electrical companies. The value is considered questionable.

Mr. Upton's endorsements of Electrical Construction and Supply Company's paper go to make up the "contingent" liabilities.

Fire in Chicago.

Early on the morning of March 4 the power-house of the North Shore Electric Railway, at Edgewater, was destroyed by fire. The generators and most of the motor cars were destroyed.

An Electrical Ball.

The first annual ball of the employees of Zimdars & Hunt, electrical contractors, took place at Lyric Hall on the evening of Washington's Birthday. The hall was handsomely decorated. The chief feature was the electrical display, which consisted of an entire electric illumination of the stage end of the hall, including some novel and surprising effects. Two columns supported an arch upon which was mounted about 75 incandescent lamps, the shafts of the columns being also entwined with smilax interspersed with roses, and round each column there were entwined about 50 electric lights.

On the caps of the columns were two American shields with flags draped each side, the colors in the shields being illuminated by numerous small electric lamps. Above the arch were numerous novel devices displayed, one reading "Employees of Zimdars & Hunt," also the formula "$C = E \div R$," which is well known to electricians, all being illuminated by numerous electric lights, making a pleasing and handsome effect. The decorations were designed by Mr. J. P. Smith and executed by the employees of Zimdars & Hunt and carried out under the superintendence of Mr. J. F. Vielberth assisted by Mr. Geo. Ruckle, Mr. J. I. C. King, Mr. George McGibney, foreman, and other employees. Mr. George T. Butler was president.

At 9 o'clock Prof. Douthwaite with full orchestra discoursed sweet music for the promenade concert, which lasted till 10 o'clock, after which the grand march took place, ending with a mazy waltz, and dancing continued until the small hours of the morning.

LEGAL NOTES.

Switch and Socket Litigation.

The U. S. Circuit Court of Appeals for the Second District has handed down a decision sustaining Judge Coxe in his decision of last summer that Perkins patent No. 247,103, owned by the G.E. Company, which they had always claimed was the great foundation patent on snap switches, is limited very closely to mechanical details.

In reference to the socket litigation a decision has also been handed down affirming Judge Coxe's decision that the fifth claim of the Johnson patent No. 251,596, covering all modern sockets in a metal case, was invalid. The fundamental Edison patent on a socket was decided by Judge Coxe to have expired December 14, 1891. So this lays aside what have been claimed to be the two primary patents on sockets.

The Court of Appeals has also affirmed Judge Coxe in sustaining the Bergmann patent No. 257,277.

The receiver of the Bergman Gas and Electrical Fixture Company, of New York, has been granted permission by Judge Lacombe, of the U. S. Court, to sell the assets, amounting to $10,000, at public auction and distribute the proceeds among the creditors.

In the case of the Cambria Iron Company vs. the Tiffin Electric Street Railway Company, at Tiffin, Ohio, Judge Schaufelberger has ordered the sale of the Tiffin Interurban Consolidated, the Tiffin Electric Railway and the Tiffin Street Railway. They are to be sold separately.

Boston Notes.

The Altham motor, about which so much has been written and said, is being exhibited in Boston and is regarded as a success. It is a new type of turbine wheel operated by a small jet of steam or a hydro-carbon fuel which is fed automatically into a generator, where its combustion produces a gas under heavy pressure, which in turn is fed to the turbine in the same way that steam is now injected. The motor now on exhibit is cylindrical in form, about 18 inches in length by about 12 inches in diameter. It is coupled directly to the shaft of the armature of an old type of dynamo, and with about 14 H. P. of steam energy it generated quite easily current for 100 lamps of 16 C. P. capacity.

Professor A. E. Dolbeare has delivered a singularly interesting and instructive lecture before the Boston Scientific Society on the "Nature of Electricity." Some beautiful experiments and illustrations of the lecturer's theory were shown, to the astonishment and delight of the interested audience.

Manchester, N. H., is becoming an important electric street railway center, and extension is the order of the day up there.

The electrical fraternity of Boston are enjoying quite a busy season for the time of year. The supply houses especially are doing well, and the amount of railway material that is being shipped to various points throughout New England is something enormous.

Keith's new theatre, which was quite recently built and finished at a cost of $600,000, is being made more and more attractive every week. The proprietor has decided to take out his entire electric lighting plant and install a new and larger one at a cost of some $50,000. It is intended to have the new plant and the room in which it will be installed the most beautiful place of its kind in the world and to be a regular show place underground. The Thompson-Brown Electric Company of Boston has got the order for the switchboard.

In the new office building which is about to be erected on the site of the old historic Tremont House, now in course of demolition, there are to be no less than 9,000 incandescent lights. It will be by far the largest building in New England. The entire cost will be about $2,700,000.

General News.

What is Going on in the Electrical World.

Phœnix, N. Y.—Orrin F. Gaylord, of Oswego, has purchased the Phœnix Electric Light Company's plant.

Dover, Del.—The House has passed the bill to incorporate the Dover and Milford Electric Railway Company.

Fremont, Neb.—The board of public works has been instructed to advertise for bids for an electric light plant.

Parsons, Pa.—At an election just held, the people of this village voted in favor of establishing an electric light plant.

Northwood, Iowa.—At the election here on the 4th inst. a vote was to be taken on the question of putting in an electric light plant.

Aitkin, Minn.—An election is to be held here in a few days to decide whether the village will bond itself in $10,000 for an electric light plant.

Quebec, Can.—An electric railway is to be built this spring in and around this city with an extension in the suburbs to the shrine of La Bonne St. Anne.

Lansing, Mich.—The car barn and nine cars of the Lansing Electric Street Railway were burned last week. The damage is estimated at $20,000.

Painesville, O.—It is rumored that Gen. J. S. Casement will take hold of the street railroad and extend it to Fairport, making an electric road of it.

Wilmington, Del.—Frank S. Garrett and Henry K. Miller have purchased the electric supply business of the Delaware Electric and Supply Company.

Knoxville, Tenn.—The council will shortly discuss the question of adopting electric lights for the city streets. Gas is used for that purpose at present.

Wichita Falls, Tex.—The Wichita Falls Construction Company are in the market for the necessary material to build eighteen miles of telegraph line, with two wires.

Yankton, S. D.—Commodore Kountz, of Pittsburg, a large property owner of Yankton, has made a proposition to the city to construct and operate an electric street railway here.

Farmersville, Tex.—At a mass-meeting here last week committees were appointed to investigate and report on the best means of securing for this city a system of water works and electric lights.

Jamaica, N. Y.—The village trustees have appointed a committee to ascertain and report what it will cost to put in an electric plant and waterworks system in Jamaica.

Sheboygan, Wis.—The Sheboygan City Railway Company have petitioned the council for permission to erect poles to put in a trolley system. The line will be extended to all parts of the city.

Brooklyn, N. Y.—Mayor Schieren has expressed himself emphatically opposed to the city doing its own electric lighting. He says municipal ownership and operation have in nearly every case proved a failure.

Reading, Pa.—A charter has been granted to a company to build an electric railway from Reading to Allentown. The capital stock is $100,000. Dr. J. S. Trexler, of Kingston, Pa., is president of the company.

Tacoma, Wash.—The Tacoma Traction Company, recently incorporated, with a capital stock of $500,000, will at once build a new power house and equip with electricity the Tacoma and Puyallup Railway, twelve miles long.

Winona, Minn.—Seward D. Livermore, of St. Paul, has been appointed receiver for the street railway and electric lighting plants of the Winona General Electric Company in this city. Mr. Livermore is a practical electrician.

Washington, D. C.—The Georgetown and Tennallytown Electric Railroad is to be operated henceforth under changed ownership. O. T. Crosby and Charles A. Lick, of New York, have, it is reported, bought a majority of the stock and will reform the directorate.

Grand Rapids, Mich.—Mayor Fisher has vetoed the action of the council ordering the issue of $150,000 bonds to build an electric lighting plant. His chief reason is that the city, with an overdrawn treasury of $90,000, cannot afford the luxury of an experiment of that kind.

Martinsburg, W. Va.—Stewart W. Walker, receiver of the Edison Electric Illuminating Company, of this city, has been authorized by the court to sell the plant of the company at Martinsburg on March 23.

Union City, Mich.—The electric light plant established here five years ago by Rhenbottom & Bond has been purchased by the city. The plant will be improved and run in connection with new waterworks.

Owosso, Mich.—Frank Lodge, president of the Owosso and Corunna street railway, now in the hands of a receiver and involved in litigation, says the road will be equipped with electricity within a year, steam being the present motor power.

New Haven, Conn.—Israel Kelsey, of Orange, who has asked the Legislature to grant him a charter for an electric road to run from Derby to New Haven, through Orange, it is said proposes to build the road just as soon as he gets the permission and the weather is favorable.

Jefferson City, Mo.—The Jefferson City Light, Heat and Power Company have decided to enlarge by adding to their present electrical equipment one 1,000-light machine to furnish current for power and light. After the additional equipment is put in they will furnish current day and night.

Burlington, N. J.—It is announced that the Pennsylvania Railroad Company is about to award the contract for equipping the Burlington branch of the Amboy Division with the trolley system. This branch connects Burlington and Mt. Holly, N. J., and is between seven and eight miles in length.

New Orleans.—A brake and controller for electric street cars has been invented by Marvin B. Monroe of this city and been tested on one of the Traction Company's cars. It worked successfully and was considered by those who witnessed the test to be an improvement on the apparatus now in use.

Salamanca, N. Y.—A company has been formed and a charter obtained for the purpose of constructing an electric road between Little Valley and this place and extending on to Great Valley. The company expects to purchase Rock City, a spot often visited by pleasure seekers, and build a hotel there.

North Adams, Mass.—S. P. Thayer, of this town, and Walter S. Kelly, of Boston, have been given a hearing before the legislative committee on mercantile affairs at Boston in behalf of the incorporation of the Hoosac Valley Electric Power Company. Their plan is to develop the water power in Readsboro, Vt., and transmit electric power by wire to North Adams and other adjoining towns.

Meridian, Miss.—J. P. Donovan, P. A. Brady, John F. McDermott and E. B. Tyler, all of St. Louis, have been granted a franchise for an electric railway to be run in this city, and also for electric lighting as soon as the present contract expires. The same parties have completed negotiations with the Meridian Street Railway Company for the purchase of all its street railway property.

Chicago, Ill.—The Cosmopolitan Electric Company has been granted by the city council a franchise for a period of fifty years. It grants the right to maintain and operate a plant or plants and to construct, maintain, and operate in, through, over and upon the streets, avenues and alleys, tunnels and viaducts, and under the Chicago river and its branches, a line or lines of wire or other electric conductors to be used for the production, transmission and distribution of electricity for the purpose of furnishing light, heat and power and the transmission of sound and signals or any and each of them.

Philadelphia, Pa.—The Atlantic Transport Line steamer British Princess, which sailed a few days ago from this port for London and Swansea, took out with her 196 iron trolley poles and fixtures made by Morris, Tasker & Co., for a line to be established in Bristol, England.—The Philadelphia Traction Company has its electric cars operating in 157.83 miles of streets, cable cars in 20.13 and horse cars in 19.76 miles. Besides these the company has under consideration extensions that will add ten miles to its system.—Bonds of $25,000 have been filed for the building of three trolley roads in West Philadelphia covering twenty seven miles of streets.

Pasadena, Cal.—The Pasadena and Los Angeles Electric Railway Co. have about completed their "loop" in this city. Power for the operation of the cars will be transmitted from the power-house at Los Angeles.—President J. S. Torrance, of the Pasadena Electric Light Company, says his company will raise the capital stock from $50,000 to $100,000 and make a large addition to the plant, a move made necessary by the growth of the city.

Albany, N. Y.—The cities committee of the Senate has reported favorably Senator Owens's bill fixing the price of electric light in cities of 800,000 population or over at one-half of a cent per hour per incandescent light and four cents per hour for arc lights.—Among the bills introduced in the Assembly last week was one providing for a five-cent fare for one continuous ride on all steam, cable or electric railroads in cities having a population of over 1,500,000.

Somerville, N. J.—Work has been started here on what will be when completed the longest trolley road in the world. The constructors now at work in constructing the road are under bonds to complete by April 10 the first five miles of the New York and Philadelphia Traction Company's proposed electric railway between the two great cities. The first rails will be laid at Raritan, after which the construction of the road will proceed at the rate of one mile per week until it connects the towns of Somerville and Bound Brook with the city of New Brunswick. The only direct means of travel between these places for more than one hundred years has been by stage coach.

New York.—The Fire Commissioners have appointed a board to examine every electrician holding a responsible position in the operation of electrical machinery in this city.—Proposals are advertised for in the *City Record* for putting in and maintaining an electrical time service, consisting of a master clock and a series of secondary clocks, with battery and necessary wirings and connections, in the courts and offices of the new Criminal Court House in this city. Bids will be received until March 15 at the office of the comptroller, Stewart Building.—A resolution offered in the board of aldermen and referred to the committee on railroads provides that hereafter all surface railway franchises consented to by the board be sold by the comptroller at public auction to the highest bidder.—All attempts to arbitrate between the striking electrical workers and the contractors have so far failed. The walking delegates threaten to extend the strike to all the building trades.

Telephone and Telegraph.

A telephone system is to be established at Linton, Ind., connecting Linton, Worthington, Bloomfield, Lyons and Switz City. An Indianapolis company is heading the project.

The net earnings of the New York and New Jersey Telephone Company for the year were reported at the annual meeting held on the 1st inst. to be $344,914 50.

The Citizens' Telephone Company of Sharon, Pa., has been granted a franchise by the council, and will enter into immediate competition with the Bell Company. The new company will use the Harrison system.

Henry W. Marshall has been elected president of the Indiana Harrison Telephone Construction Company, succeeding Hon. John R. Coffroth, whose stock in the Construction Company he purchased. The other officers of the the corporation are; Geo. P. Haywood, first vice-president; E. H. Andress, second vice-president and assistant secretary; Wm. Taylor, treasurer; E. G. Leszynsky, secretary and general manager.

The Central Telephone Company is arranging to rebuild its system at Quincy, Ill., Jacksonville and Springfield, also to run a long-distance wire down the Illinois and Michigan Canal from Chicago to Ottawa, Decatur, Springfield and St. Louis, with a branch to Jacksonville and Quincy.

A telephone company has been organized at Pensacola, Fla., and will apply for a charter at once. The officers of the company are: President, T. E. Wells; vice-president, H. T. Wright; secretary, L. Jacoby; treasurer, W. A. l'Alemberte; directors: T. E. Wells, John Cosgrove, H. T. Wright, T. C. Watson, Rix M. Robinson, A. C. Blount and Pat McHugh.

Augusta, Ga., and Aiken, S. C., have been recently telephonically connected.

The telephone line between Lincolnton and Washington, Ga., has been sold to P. J. Halliday for $5. The line had become inefficient and out of repair. Mr. Halliday will renew the wires and equipment and continue the service.

Spartanburg, S. C., talks of forming a joint-stock company to compete with the Bell Telephone Company, whose charges are not relished by the business men of the town.

The Phœnix Telephone Company is making inroads at a lively pace into the Bell company's business at Traverse City, Mich. The first-named company has already obtained about 150 subscribers. The Bell company will reduce its rates.

St. Louis is still without long-distance telephone service, and can't even talk direct with her great rival, Chicago.

The Terre Haute, Ind., council has granted a franchise to the Indiana Harrison Telephone Construction Company, to run twenty years.

If either of three bills now before the Massachusetts Legislature becomes law, telephone and telegraph companies will be subject to the supervision of a commission created for the purpose.

W. H. McCullough, auditor of the Great Southern Telegraph and Telephone Company, has been investigating the feasibility of constructing a telephone line between Natchez and St. Joseph, La. If the line is built it will give the entire front of the Fifth Louisiana Levee District telephone communication, which would be of inestimable advantage in flood seasons.

The Committee on Law of the Philadelphia city councils have decided to report in favor of repealing the ordinance granting the Mutual Automatic Telephonic Company a franchise, on the ground that its passage was obtained through corrupt influences. An investigation has been in progress for several weeks to find out whether there was any truth in the charge.

Evansville, Ind., expects to enjoy the advantage of the long-distance telephone service before the ensuing summer is over. The arrangements have been made by the Cumberland Telephone and Telegraph Company. The new service will connect the Evansville exchange with the local exchanges in the following States: Maine, New Hampshire, Vermont, New York, Massachusetts, New Jersey, Maryland, Pennsylvania, Ohio, Indiana, Illinois, Wisconsin and Minnesota.

Over two-thirds of the stock of the new telephone company at Petersburg, Va., has been subscribed for. It cannot be positively stated whether or not the new company will be organized in case the demands of the committee for cheaper rates are conceded by the local Bell company. Some of the parties who have subscribed for stock are said to be in favor of going ahead with the organization of the company in any event, as they believe it will prove a profitable investment.

The Metropolitan Telephone and Telegraph Company of New York announces that extra toll charges will not be made for messages from subscribers' stations to public pay stations.

The Mexican Telephone Company has added another exchange with about sixty subscribers to its service. The new exchange is at Campeche, was put in operation about January 1, and showed net profits of about $180 the first month. The rental of instruments is $10 per month.

The borough council of Kennett Square, Pa., has passed an ordinance taxing all telegraph, telephone and electric light poles standing in the borough one dollar per year.

The city council of Anderson, Ind., has granted franchises to both the Harrison and American Telephone Companies, and these and the Bell Telephone Company, already operating, are expected to go on cutting rates until they get down as low as 50 cents a month.

The Traders' League in Philadelphia have issued an appeal to business men to aid them in their opposition to Congressional measures tending to prolong the monopoly of the Bell Telephone Company. The joint committee of the league, in the report embodying the appeal referred to, say: "As Judge Carpenter, of the United States Circuit Court, has publicly criticised the work of the Patent Office in connection

with patents issued to the Bell Company or its assignors, it is very plain that the Patent Office ought to be overhauled. We therefore respectfully request you to ask your Representatives in Congress to ask for an investigation into the Patent Office and its methods."

A new telephone company has applied for a franchise to establish a complete telephone service in Atlanta, Ga. Among the men who have petitioned the city council for the franchise are Captain A. J. West, James R. Collins, T. B. Brady, F. Hardy, N. C. Boyster, A. P. Morgan, A. L. Glenn and J. W. McPherson.

The Harrison Telephone Company will begin erecting its plant at Fort Wayne, Ind., as soon as the condition of the ground permits.

A new telephone company has been organized in Pittsburg, Pa., and in view of this fact the vice president of the established Bell company, in an interview on the question of rates, says his company does not contemplate any reduction.

The plan devised by Prof. Lucien I. Blake, of the Kansas State University at Lawrence, for telephoning to a vessel anchored a long distance off the coast, has been successfully tested at Sandy Hook between the shore and Scotland lightship, several miles off. The difficulty presented by the vessel's continual change of position was the problem to be solved in getting the current from the cable at the bottom of the sea to the deck. Prof. Blake has solved this by attaching to the anchor another chain leading a sufficient distance toward the shore to avoid any disturbance by the movements of the vessel, and using the chains for transmission of the current to the deck from the connected cable.

H. L. Baldwin, of Watertown, N. Y., has petitioned the Watertown council for a telephone franchise in that city.

The Southwestern Illinois Telephone Company, just incorporated, with a capital stock of $100,000, proposes to open and operate a telephone exchange in East St. Louis. The incorporators are Anthony Isch, Daniel Sullivan and W. A. Rodenburg.

A telephone company has been organized for the purpose of constructing a line from Fargo to Grand Forks, N. D. The company is now on the road securing the right of way between Fargo and Hillsboro, and work will be commenced as early in the spring as possible.

A new company, to be known as the Bell Telephone Company, is being organized at Bedford City, Va. It offers cheaper telephone rates than those of the existing company.

The council of Argentine, Mo., has granted a franchise to the Silver City Telephone Company to do a telephone business in Argentine.

COMMERCIAL PARAGRAPHS.

The Metropolitan Electric Company of Chicago are introducing to the trade a new Carbon Battery of high efficiency test for open circuit work. The battery is guaranteed and offered to the trade seeking a high-class article of this description.

The F. E. Belden Mica Mining Company of Boston, Mass., miners and dealers in mica and manufacturers of ground mica, quartz, flint and silex, have established a branch at 182 Franklin street, New York (Union Adams, Jr., agent), where all their products may be found.

Storage Battery Plant for Light and Railway at Merrill, Wis.

Merrill, with a population of about 9,000, is situated 352 miles northwest of Chicago, in the lumber regions of Wisconsin, on the Wisconsin River. The city is divided into two parts, the Eastside and the Westside, by the Prairie River, which here flows into the Wisconsin. The Merrill Light and Railway Company furnishes all electric light in the city and operates the electric railway connecting the Eastside and Westside.

The electric lighting of the city is divided between two stations, that on the Eastside being run from a water-power plant and the Westside from a steam-power plant. The railway generator is operated by a water wheel at the Eastside station.

Some months ago the company was brought face to face with that problem, so frequently occurring in the electrical field, of the best plan for enlarging the power plant to meet the requirements of increasing demand.

After much discussion of the question, it was decided to install a storage battery plant in a sub-station at or near the distant light center, the power-house itself being at one center.

It was decided that the battery should not only be utilized for increasing the light capacity, but also for regulating the voltage on the railway circuit.

The storage battery plant, recently installed, is situated midway between the East and West sides, on line of trolley road. The plant contains 240 eleven "F" Chloride Accumulators, capacity 500 ampere hours at 50 ampere rate, manufactured by the Electric Storage Battery Company of Philadelphia. The batteries are divided into four series of 60 cells each, connected to a switchboard so arranged that cells may be connected to railway, 240 in series, or to lighting circuits, two parallel series of 60 cells each, on each side of three-wire system, capable of supplying, normally, four hundred 16-candle power lamps for ten hours, or, at maximum discharge, 600 lamps. An independent feeder connects battery with the Eastside power-house, three-quarters of a mile distant. A variable resistance is placed in circuit between battery and railway, so that when battery is fully charged, requiring a voltage of 600, the voltage on railway may be cut down if necessary.

On January 4, 1895, the battery was connected to railway circuit. The great improvement in running of cars was immediately noted by all, but it was at night that the contrast was most apparent. The two water wheels were connected together as usual, but the railway generator charged the battery at almost a steady rate, instead of running a car with its ever-varying demand of from 0 to 120 amperes. Instead of one dimly-lighted, slow-running car, two brilliantly-lighted cars were operating at the highest speed allowable on the streets. Instead of a succession of sharp peaks, the voltage curve of lighting circuit became practically a straight line; instead of nine volts variation on each side of three-wire system, as at first, there was practically no variation, demonstrating most clearly the capability of battery to respond to all demands of railway, no matter how severe.

On several occasions the two cars were operated by the battery alone for several hours at a stretch, thus in the daytime allowing of the entire shutting down of power plant and at night of the use of the two water wheels exclusively for lighting.

This installation most clearly demonstrates the great value of storage battery installation in connection with light and railway plants: First, as a reservoir in which to store up energy otherwise lost—the difference between the average demand and maximum demand on a generating plant; second, as a regulator of pressure on circuits subject to fluctuating demands. Many street railways could thus add materially to their income by establishing storage battery sub-stations along their lines, to be charged direct from the trolley or trolley feeders and furnishing current of almost any desired voltage for light and power purposes.

The Walker Manufacturing Company.

Among some of the larger orders taken already this year by the Walker Manufacturing Co., Cleveland, Ohio, may be mentioned the following:

The Complete Electric Construction Co., New York City, two 50 K. W. belted lighting generators.

The Rahway Electric Railway Co., Rahway, N. J., one 100 K. W. belted multipolar generator; three double car equipments, 25 H.P. spring mounted steel motors.

The Philadelphia Construction Co., Philadelphia, Pa., for the Schuylkill Electric Railway Co., Pottsville, Pa.; three 400 K. W. belted generators and switchboard apparatus; two double car equipments, 25 H. P. motors.

The Michigan Electric Co., Detroit, Mich., for Saginaw Consolidated Street Railway Co., Saginaw, Mich., one 200 K. W. belted generator; six complete car equipments, 25 H. P. motors.

Hartford and West Hartford Street Railroad Co., Hartford, Conn., two double car equipments, 50 H. P. steel motors; two double car equipments, 25 H. P. steel motors.

C. E. Loss & Co., Chicago, Ill., for Waukesha Street Railway Co., Waukesha, Wis., one 150 K. W. belted generator; three double car equipments, 50 H. P. steel motors.

The Detroit Railway, Detroit, Mich., two 400 K.W. direct coupled generators; one 750 K. W. direct coupled generator.

Gloucester, Essex and Beverly Street Railway Co., Gloucester, Mass.; three 225 K. W. direct coupled generators.

The Worcester Construction Co., Worcester, Mass., for the Gloucester, Essex and Beverly Street Railway Co., sixteen double car equipments, 25 H. P. steel motors.

Jaspar County Electric Railroad Co., Carthage, Mo., two 200 K. W. belted generators; five double car equipments, 30 H. P steel motors.

Besides the above, they have taken orders for their spring mounted steel motors for the Louisville Railway Co., Louisville, Ky.; Atlantic Avenue Railway Co., Brooklyn; Ottumwa Electric Railway Co., Ottumwa, Iowa; Aurora Street Railway Co., Aurora, Ill.; Bloomington City Railway Co., Bloomington, Ill.; Steinway Railway Co., Brooklyn; Kansas City Railway Co., Kansas City; Atlanta Electric Railway Co., Atlanta, and many others.

They have also taken large orders for their general work, among which may be mentioned contract for four 2,000 ton hydraulic cotton compresses for Mr. W. W. Bierce, Montgomery, Ala.

Siemens & Halske Generators in Philadelphia.

The People's Traction Company of Philadelphia have placed an order for three 870 kilowatt Railway Generators, running at 80 revolutions per minute, to be direct coupled to engines, with Messrs. Walker & Kepler, of Philadelphia, representatives of the Siemens & Halske Electric Company in Pennsylvania.

This order was placed with the Siemens & Halske Company after the experts of the People's Traction Company had made a careful examination of the Siemens & Halske machinery at their works in Chicago.

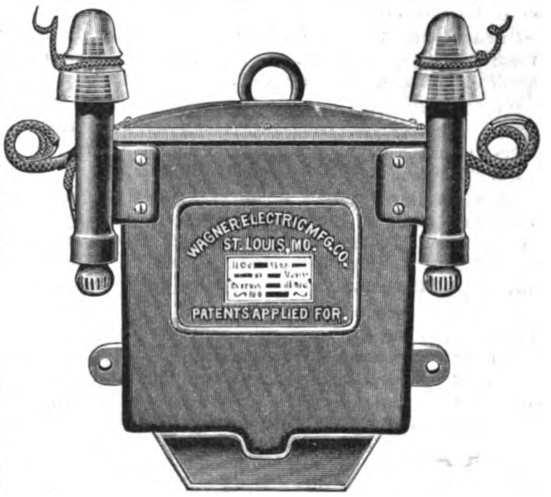
Bristol Recording Voltmeters.

Mr. J. Fred Galletly, electrician for Swift & Company, Chicago, in discussing recently his experience with incandescent lamps, said that he believed fully half the troubles usually credited to poor lamps were the result of lack of care on the part of the dynamo tender. His plant at the stock yards takes about 9,000 lamps. His breakages had been enormous until he was induced to add the Bristol Recording Voltmeter to his equipment, since which time his assistants realize that their care, or lack of it, in maintaining an even voltage is at once apparent, and the breakages are reduced to a minimum. Mr. Galletly says that the saving in this direction alone since putting in the recording voltmeter, is more than $50 per week.

Wagner Transformers.

The new transformers of the Wagner Electrical Manufacturing Company, first introduced to the public at the Cleveland Convention, bid fair to take their place at once in the popular estimation alongside of the best in the market. Their construction possesses so many points of merit that many central station men placed orders at the meeting.

The chief claims for consideration are that the transformer, primary cut-outs and insulator brackets are all in one, that trouble with primary fuses is entirely averted, and that by their use absolute protection both to lines and transformers is secured. They are made with either dry or oil insulation as desired, and with either attached or separate primary cut-outs.



WAGNER TYPE "D" TRANSFORMER.

Further information can be gained at the company's home office, St. Louis, or at either of its branch offices, Monadnock Building, Chicago, or Betz Building, Philadelphia.

Mather Company's Sales.

The Mather Electric Company of Manchester, Conn., report a continuation of the unprecedented amount of new business secured. The following sales have recently been made through their isolated lighting plant: The Berlin Iron Bridge Company, East Berlin, Conn. (second order); 250 light ring type dynamo; Perkins Electric Switch Manufacturing Company, Hartford, Conn., 350 light ring type dynamo; Haverhill Paper Company, Bradford, Mass., 150 light ring type dynamo; Inter-Mountain Electric Company, Pocatello, Idaho, 450 light ring type dynamo; Hub Gore Makers, Brockton, Mass., 450 light ring type dynamo; Coffee Exchange, New York City, 600 light ring type dynamo; Iroquois Furnace Company, 150 light ring type dynamo; Cranston Worsted Mills, Bristol, R. I., 250 light ring type dynamo; New Opera House, Holyoke, Mass., 250 light ring type dynamo; Hub Gore Makers, Camden, N. J., 150 light ring type dynamo; Waverly Woolen Company, Pittsfield, Maine (second order), 350 light ring type dynamo; Thatcher Bros., New Bedford, Mass., 100 light ring type dynamo; Jas. F. Grant, Youngstown, Ohio, 450 light ring type dynamo: Rockwell Manufacturing Company, Milwaukee, Wis. (second order), 100 light ring type dynamo; Burtis & Howard, Minneapolis, Minn. (third order), 100 light ring type dynamo; S. N. Blake Elmira, N. Y., two 250 light ring type dynamos; B. Lowenstein & Bros., Memphis, Tenn., 100 light ring type dynamo; Straight Line Engine Company, Straight Line, New York, 20 K. W. Manchester type generator;

Cook Locomotive Works, Paterson, N. J., 45 K. W. 220 volt multipolar generator; J. Holt Gates, Chicago, Ill., two 60 K. W. multipolar generators, 500 volts; Denison Light and Power Company, Denison, Tex., 45 K. W. multipolar generator, 220 volts.

RECENT COMPANY ELECTIONS.

Bell Telephone Company of Missouri, St. Louis. Directors: Henry B. Stone, Charles C. Maffitt, Arthur I. Fuller, James Campbell, John E. Hudson, Edwards Whitaker, W. H. Forbes, William Duncan, C. Jay French, George G Hall and Alonzo Burt.

Bangor, Orono and Old Town Railroad Company, Bangor, Me. Directors: J. C. Libby, C. A. Richardson, A. F. Gerald, J. Manchester Haynes, F. O. Beal, J. F. Gould, A. J. Durgin.

Washington, Alexandria and Mt. Vernon Electric Railway Company. President, G. E. Abbott: vice-president, Frank A. Reed; treasurer, D. C. Leach: assistant treasurer, D. W. Holden; secretary, F. K. Hipple; auditor, J. A. Swartz. The officers named, together with J. S. Swartz and James R. Caton, form the board of directors.

The Maryland Electric Company, Baltimore. President and treasurer, W. B. Putney, of New York; vice-president and secretary, A. A. Glasier, of Boston. Directors: W. B. Putney, A. A. Glasier, R. T. McDonald of Fort Wayne, Ind.; Joseph P. Smith and W. H. Garrison of Baltimore.

Marble City Electric Company, Rutland, Vt. President and treasurer, F. M. Butler; secretary, James Carruthers; auditor, H. O. Edson. Directors: F. M. Butler, Henry O. Edson, A. C. Bates, H. M. Bates, T. W. Moloney, S. W. Bassett, James Carruthers.

City and Suburban Railway Company, Savannah, Ga. President, James H. Johnston; vice-president, Henry Parsons; secretary, E. J. Thomas; treasurer, E. Schmitt. Directors: J. H. Johnston, Henry Parsons, E. J. Thomas, J. N. Harriman, Luke Carson, C. S. Hardee.

Orleans Street Railroad Company, New Orleans. Directors: Paul Capdavielle, U. Koen, A. Fitzpatrick, Peter Congot, C. M. Harrod, N. C. Cromwell, and F. L. Limongi.

Hamilton Electric Light and Power Company, Hamilton, Can. Directors: R. Thomson, president; John Knox, vice-president; J. V. Teetzel, secretary-treasurer, and Alex. Turner, S. F. McKinnon and H. M. Pellatt.

Beaver Valley Traction Company, Beaver Falls, Pa. President, John M. Buchanan; treasurer, R. P. Stone; secretary, A. D. Long. Directors: Dr. T. P. Simpson, A. R. Leyda, A. M. Jolly, J. C. Whitla, Robert S. Kennedy, Dr. H. S. McConnell.

Hingham Electric Railway Company, Hingham, Mass. President, Sidney Cushing; secretary and treasurer, W. C. Foster. Directors: Sidney Cushing, J. J. Moore, B. C. Wilder, E. H. Gowing, E. F. Wilder, C. H. Marble and W. B. Foster.

Lowell Electric Light Corporation, Lowell, Mass. President, George W. Fifield; vice-president, W. A. Ingham: treasurer, William H. Burt. Directors: George W. Fifield, W. A. Ingham, William H. Bent, P. P. Perham, L. T. Fletcher, James H. Tolles and Charles S. Collins.

Bell Telephone Company, Buffalo, N. Y. Directors: Henry Altman, Philo D. Beard, Benjamin E. Chase, Clarence O. Howard, Edward J. Hall, John E. Hudson, Porter Norton, David B. Parker, Thomas T. Ramsdell, Sherman S. Rogers, Samuel S. Spaulding, Henry M. Watson, William H. Watson, George Weldon and John L. Williams.

Holmes Electric Protection Company, Toronto, Can. President, T. G. Blackstock; vice-president J. B. Wood; secretary-treasurer, A. S. Wigmore. Directors: T. G. Blackstock, W. B. McMurrich, L. K Cameron, B. Jennings, F. A. Ritchie, A. S. Wigmore and J. B. Wood. In Montreal the same company re-elected the old board of directors.

INCORPORATIONS.

The Murphysboro Gas Light Company, Murphysboro, Ill.—to manufacture gas for light and power, maintain and operate waterworks and electric light plants. Capital stock, $80,000. Promoters: J. D. Peters, P. M. Post, W. C. Norman, Geo. E. Kirchner.

The Cambridge City Electric Light Company, Cambridge, Ind. Capital stock, $20,000. Promoters: Edward W. Boden, Chas. H. Kerlin, Thos. B. Stephens.

The Fuller Electric Engineering Company, East St. Louis, Ill.—to manufacture and deal in electric appliances of all kinds, build and operate electric plants and carry on a general electrical business. Capital stock, $30,000. Promoters: W. A. Fuller, Charles T. Dana, C. H. Dudley.

The Onondaga Dynamo Company, Syracuse, N. Y.—to manufacture and sell dynamos, electrical machinery, etc. Capital stock, $25,000. Promoters: Ella H. Eager, J. W. Eager, David Cronin, all of Syracuse, N. Y.

The Oxley, Giddings and Enos Company, New York City, N. Y.—to deal in gas and electric light fixtures, etc. Capital stock, $200,000. Promoters: W. F. Moody, Bayonne, N. J.; Frederick Wilcox, Brooklyn, N. Y.; W. N. Robertson, Jersey City, N. J.

The Harrisburg and Cumberland Electric Railway Company, Harrisburg, Pa.—to construct and operate an electric railway. Capital stock, $36,000. Promoters: Wm. L. Corgas, Frank R. Leib, S. W. Fleming, Harrisburg.

The Citizens' Electric Light and Power Company, Hughesville, Pa.—to supply light, heat and power by means of electricity. Capital stock, $6,000. Promoters: William Frontz, Peter Rooden, Hughesville; James K. Boak.

The Pennsylvania Heat, Light and Power Company, Philadelphia, Pa.—to manufacture and supply light, heat and power by means of electricity. Capital stock, $10,000. Promoters: Robt. Reaves, C. W. McKinney, John Taylor, Scranton, Pa.

The Hillsborough Electric Light and Power Company, Hillsborough Bridge, N. H.—to manufacture and supply electricity for light, heat and power. Capital stock, $25,000. Promoters: James F. Grimes, Harvey Jones, Geo W. Lincoln, Wilson D. Forsaith, Hillsborough Bridge.

The Jaeger Electric Lamp Company, Newark, N. J.—to manufacture, sell and deal in electrical lamps, etc. Capital stock, $10,000. Promoters: Herman J. Yaeger, Norman D. Webster, Brooklyn, N. Y.; Louis J. Auerbacher, Newark, N. J.

The Harrison Electric Company, Chicago, Ill.—to manufacture all kinds of electrical machinery, appliances and devices. Capital stock, $500,000. Promoters: Edward M. Harrison, Lewis H. Painter, Lewis Rinaker.

The Scoville Island Street Railway Company—to build and operate an electric road from Wyoming, Pa., to Old Forge, six miles. Capital stock, $36,000. The officers of the company are: President, Wm. S. Tonkins. Directors: E. B. Long, E. A. Corry, Jr., of Pittston: C. D. Simpkins and H. M. Straeter, of Scranton, Pa.

The Manhattan Electric Storage Battery Company of New York City—to manufacture and sell electric storage batteries or accumulators and any appliances connected therewith. Capital stock, $600,000. Directors: August Belmont, James H. Hoffman, Louis Stein, Lewis May and Ignatz Boskowicz, of New York City.

The Montgomery Electric Company of Ambler, Pa. Capital stock, $1,000. Incorporators: E. A. Murphy, R. L. Parkinson, A. M. Slocum and Henry Parker, of Philadelphia, and others.

The Vermillion Water, Light and Power Company, Vermillion, S. D.—to furnish water and light to the city of Vermillion, S. D. Capital stock, $25,000. Promoters; G. T. Salmer, S. E. Brookman, E. Brookman, all of Vermillion.

The Commercial Heat and Power Company, Chicago, Ill.—to construct, maintain and operate a plant for heat and power; construct and maintain mains, pipes, etc. Capital stock, $2,000,000. Promoters: Dan'l V. Harkin, Harry C. Colson, M. W. Cagney.

The Los Angeles Traction Company, Jacksonville, Ill.—to construct, lease, purchase and operate street railways in the State of California. Capital stock, $100,000. Promoters: Thos. J. Hook, Francis Hook, Marcus Hook.

The Cosmopolitan Electric Company, Chicago, Ill.—to manufacture and generate electricity, construct plants, etc. Capital stock, $2,000,000. Promoters: Albert H. Tyrrell, Wm. H. Pope, Walter H. Marble.

The Third Street and Suburban Railway Company, Seattle, Wash.—to build, own and operate street railway, electric light and power plants, saw mills, etc. Capital stock, $100,000. Promoters: August Mackintosh, A. N. Brookes, Frederick Bausman, W. C. Crambs, Thos. Boyd, David T. Denny, D. Thomas Denny.

The Hickley Launch and Electrical Engineering Company, Asbury Park, N. J.—to supply power for electric light and heat and other electrical appliances, etc. Capital stock, $100,000. Promoters: Arthur S. Hickley, Myron S. Gould, Cook Howland, Asbury Park, N. J.; Claude V. Guerin, Ocean Grove, N. J.

The Dexter and Brownsville Street Railway Company, Watertown, N. Y.—to build and operate a street surface electric railway in Jefferson County, N. Y., to connect the villages of Dexter, Brownsville and Sacketts Harbor. Capital stock, $40,000. Directors: Byron B. Taggart, Hiram F. Inglehart, Joseph Mullin, George H. Walker, B. B. Taggart, Jr., Chester C. Inglehart and N. P. Wardwell, of Watertown; J. A. Lebkeucher, and J. Krementz, of Newark, N. J.

The Franklin Electric Illuminating Company, Oyster Bay, L. I., N. Y.—to manufacture and use electricity for producing light, heat and power in the villages of Sea Cliff, Glen Cove, etc., in Queens County, N. Y. Capital stock, $25,000. Directors: Samuel Stenson, John Graham, W. A. Porter, D. W. Pardee, of Sea Cliff; Louis T. Duryea, James Norton, of Glen Cove; Frank D. White and Henry F. Noyes, of Brooklyn, and James Tychborne, of Mount Vernon.

The Queens County Telephone and Telegraph and Supply Company—to connect the village of Oyster Bay, Queens County, with the village of Huntington, Suffolk County, by way of Cold Spring Harbor from Oyster Bay to Hicksville, by way of Syossett and intermediate points from Oyster Bay to Flushing, by way of Glen Cove, Roslyn and intermediate points. Capital stock, $20,000. Directors: W. L. Swan, G. W. Foller, Samuel Y. Bayles, of Oyster Bay; U. S. Croft, of Brooklyn; R. Downing, W. F. Johnson and E. Morgan Griffin, of East Norwich, Conn.

Batavia Street Railroad Company—to operate an electric street surface railroad from Batavia to Horse Shoe Lake, a distance of seven and a half miles. Capital stock, $75,000. Directors: Amos H. Stephens, A. B. Wilgus, J. H. Wilgus, J. S. Lindsay, C. C. Marsh, of New York City; H. B. Burdick, of Malden, Mass.; F. P. Wilgus and Mark Sugarman, of Brooklyn; F. J. Fadner, of Chicago.

The Howard H. Bowen Company, San Francisco, Cal.—to manufacture and deal in gas, electric and combination fixtures, electroplating and art metal work, etc. Capital stock, $50,000 Promoters: Howard H. Bowen, Sam Soloman, Carl Rector, J. L. Franklin, Chas. A. Partridge, all of San Francisco.

The McLean Armature Company, Chicago, Ill.—to do general electrical repair and manufacture electrical apparatus. Capital stock, $15,000. Promoters: James McLean, John S. Parmele, Martin R. Nelson.

ELECTRICAL PATENT RECORD.

LETTERS PATENT ISSUED FEBRUARY 26, 1895

ELECTRIC RAILROADS AND APPLIANCES.

534,642. Railway Supply System. Harding F. Gray, Passaic, N. J., assignor to the Gray Electrical Transit Company, of New Jersey. Filed Aug. 8, 1893.

534,662. Electric Railway System. Herluf A. F. Petersen, Milwaukee, Wis. Filed Nov. 8, 1893.

534,663. Underground Conduit for Electric Railways. Herluf A. F. Petersen, Milwaukee, Wis. Filed Mar. 26, 1894.

534,834. Battery System for Electric Railways. Edmond Julien, Brussels, Belgium, assignor to the Electric Storage Battery Company, Gloucester, N. J. Filed Dec. 9, 1886.

534,956. Electric Trolley Railway. Joshua M. Hammill, Aldan, assignor of one-fourth to John S. Latta and James J. Mulconroy, Philadelphia, Pa. Filed Jan 23, 1894.

534,986. Conduit Electric Railway. Michael F. Flynn, Stamford, Conn. Filed May 24, 1894.

ELECTRIC LIGHTS AND APPLIANCES.

534,677. Electric-Arc Lamp. Hans O. Swoboda, New York, N. Y., assignor to the General Incandescent Arc Light Company, same place. Filed Apr. 6, 1894.

534,852. Electric-Arc Lamp. James Brockie, Forest Hill, England. Filed Nov. 13, 1894.

534,886. Electrical Lighting Device for Gas-Engines. Calvin L. Ives, Grand Rapids, Mich. Filed Mar. 30, 1894.

534,971. Incandescent Light. Henry F. Rooney, Randolph, Mass. Filed Nov. 17, 1894.

DYNAMO ELECTRIC MACHINERY.

534,678. Electric-Current Transformer. Joseph A. G. Trudeau, Ottawa, Canada. Filed Apr. 6, 1894.

534,729. Commutator. David P. Thomson, Schenectady, N. Y., assignor to the Thomson-Houston Electric Company, Boston, Mass. Filed Dec. 17, 1894.

534,851. Driving Mechanism for Dynamos Located on Railway-Cars. William L. Bliss, Brooklyn, N. Y. Filed Aug. 17, 1894.

534,953. Dynamo-Electric Machine. Rudolf Eickemeyer, Yonkers, N. Y. Filed June 7, 1888.

TELEPHONE AND TELEGRAPH APPARATUS.

534,639. Printing-Telegraph. Samuel V. Essick, Brooklyn, N. Y. Filed Sept. 18, 1890.

534,670. Telegraph and Telephone System. Charles A. Rolfe, Chicago, Ill. Filed Sept. 16, 1893.

534,671. Fire-Alarm-Telegraph System. Charles A. Rolfe, Chicago, Ill. Filed Apr. 10, 1894.

534,970. Telegraph and Telephone System. Charles A. Rolfe, Chicago, Ill., assignor to the Police Telephone and Signal Company, same place. Filed Feb. 15, 1893.

SIGNALS AND SIGNALING APPARATUS.

534,779. Signaling System. Clarence B. Brace, Union City, Mich. Filed Nov. 27, 1894.

534,815. Electric Slot for Signals. John P. Coleman, Swissvale, Pa., assignor to the Union Switch and Signal Company, same place. Filed Sept. 27, 1893.

534,908. Electric Signaling Apparatus. Bernice J. Noyes, Boston, Mass., assignor to George W. Gregory, same place. Filed July 5, 1892.

MISCELLANEOUS.

534,640. Recording Watt-Meter. Walter C. Fish, Lynn, assignor to the Thomson-Houston Electric Company, Boston, Mass. Filed Dec. 22, 1894.

534,650. Electrically-Actuated Combination-Lock. Samuel L. G. Knox, Camden, N. J. Filed Apr. 13, 1894.

534,699. Electric Resistance-Card. Alton J. Shaw, Muskegon, Mich. Filed Dec. 1, 1894.

534,732. Connector for Electric Conductors. Robert D. Titcomb, Schenectady, N. Y., assignor to the Thomson-Houston Electric Company, Boston, Mass. Filed Dec. 21, 1894.

534,785. Method of and Apparatus for Insulating Electrical Conductors. Louis W. Downes, Providence, R. I. Filed Aug. 22, 1894.

534,786. Apparatus for Manufacture of Insulated Electrical Conductors. Louis W. Downes, Providence, R. I. Filed Dec. 11, 1894.

534,802. Electric Metal-Working Apparatus. Hermann Lemp, Lynn, Mass., assignor to the Thomson Electric Welding Company, of Maine. Filed Dec. 3, 1892.

534,942. Manufacture of Articles by Electrodeposit. Henry S. Anderson, Springfield, Mass. Filed Dec. 18, 1889.

534,961. Electrically-Operated Keg-Register. Josef Kuff, New York, N. Y., assignor, by mesne assignments, of one-half to Mary A. Richter, same place. Filed Apr. 4, 1894.

534,974. Electric Brake. Elmer A. Sperry, Cleveland, Ohio, assignor to the Sperry Electric Railway Company, of Ohio. Filed Jan. 30, 1894.

534,975. Apparatus for Arresting Motion of Electrically-Propelled Mechanism. Elmer A. Sperry, Cleveland, Ohio, assignor to the Sperry Electric Railway Company, of Ohio. Filed Feb. 5, 1894.

534,977. Electric Brake. Elmer A. Sperry, Cleveland, Ohio, assignor to the Sperry Electric Railway Company, of Ohio. Filed June 8, 1894.

ELECTRICITY.

Vol. VIII. NEW YORK, MARCH 13, 1895. No. 9

ELECTRICITY

Published every Wednesday by the

ELECTRICITY NEWSPAPER CO.

B. E. GREENE, PRES'T. L. J. MONTGOMERY, SEC'Y.

PUBLICATION OFFICE:

6 Park Place - New York

EDITORS: NELSON W. PERRY.
BURTON E. GREENE.
R. H. WILLOUGHBY.

SUBSCRIPTION RATES:

UNITED STATES,	$2.50
IN CLUBS OF FIVE OR MORE,	$2.00
FOREIGN COUNTRIES,	$4.50
SINGLE COPIES,	10 CENTS

ADVERTISING RATES:

As ELECTRICITY reaches all classes interested in electrical work, its value as an advertising medium can be readily appreciated. Rates will be sent on application.

Changes for advertisements should reach the office not later than the Saturday preceding the date of publication.

ENTERED AT THE N. Y. POST OFFICE AS MAIL MATTER OF THE SECOND-CLASS.

TRADE SUPPLIED BY
THE AMERICAN NEWS COMPANY,
THE WESTERN NEWS COMPANY,
And their Agencies in all Principal Cities.

EDITORIAL NOTES.

THE LAMP SITUATION.

The recent decision of the United States Supreme Court in the Bate case, throwing open forever the field of incandescent lamp manufacture, and the changed conditions resulting therefrom, are matters of far more importance to the independent lamp companies and to the public than to the General Electric Company itself, and presents strong reasons for a careful consideration of the situation. That the G. E. Company is affected to a smaller degree than the independent companies will not be apparent, perhaps, to the casual looker-on, but it is a fact. A favorable decision in this case would have given the G. E. Company only a negative victory, and one which they did not expect. It would not have given them control of the lamp situation, and they would have been compelled to meet the competition of at least two companies—the Columbia and Buckeye lamp companies—which could not have been closed up—if at all—much before the limit of the patent which it was hoped to establish.

After the long battle, in which the Edison lamp has been at no time an undisputed winner, the situation is revolutionized. Litigation is ended—barring the possible victory of the Westinghouse interests in the McKeesport case, which case, we think we are safe in saying, interests only the two large companies, General Electric and Westinghouse.

The question now arises, what is the lamp business worth to those engaged in it? Prices have been, as we all know, reduced one-half from the basis of 1892. There is, however, at present prices a fair margin of profit left; as large, probably, as that in most lines of manufacture.

Competition will be fierce. Those who have stood together in opposition to the Edison interests have already separated, actuated by the motives which have controlled human action since the world began--self-interest.

Of those who are already in the business, and those who will enter it soon, not all will remain on January 1, 1896. Who will survive? First, of course, those companies which have a respectable working capital, but the sure winners will be the ones who make the *best product possible*, and who refuse to sell *one lamp* unless a fair profit can be made. If there is any revolutionary cutting of prices to be done it should be left to those who are conducting their business as stockjobbing enterprises and not as legitimate business concerns.

At the present writing the new prices of the G. E. Company are not published, but ELECTRICITY is in possession of the facts.

Edison licensees can buy their 16 C. P. lamps at 17 to 18 cents. This is as it should be. They have paid for something which they never got, and the least which the parent company can do now is to give them lamps at cost. The price to ordinary users will be 24 cents, and other sizes in proportion.

We hear plenty of talk from lamp makers as to the remarkable results they have achieved in reducing the cost of lamps. Most of it can be brushed aside as trade buncombe—all right in its place, but not to be relied on by stockholders and investors.

ELECTRICITY has investigated the question thoroughly, and we stand as authority for the statement that no lamp maker in this country can make lamps for less than 17 cents. We therefore make the prophecy, advisedly and with knowledge that it will prove correct, that any company endeavoring to sell lamps much below present prices is not a safe concern to trust with the money of stockholders or with commercial credit.

The competitive fight is on; there will be vigorous competition, and the victors will be those who are guided by common sense and by the established laws of business.

It is not often that the duty of the purchaser, sentimentally considered, coincides so nearly with his duty to himself as in the present incandescent lamp situation.

That duty is to purchase lamps of the independent companies.

Notwithstanding the protracted litigation over the validity of the Edison lamp patent, the extended discussion in the trade press of its various features, comparatively few of those engaged in the business to-day have a clear conception of the actual facts. The situation has been so muddled up by complicated arguments and by points of law that the average layman, including the judges of our highest courts, has not been able to untangle the true from the false, or to characterize properly the position of the independent lamp companies and of the Edison Company.

We have heard it said within a week, by those who ought to know better, that these independent companies have no claims upon the public; that they had placed themselves in the position of infringers of a patent duly sustained, and had refused to bow to the decrees of the courts; that if they had been governed by honorable motives they would have retired from the field immediately after Judge Wallace's decision in 1891.

Nothing could be further from the truth.

The Edison lamp patent has now passed into history. Even the most bitter partisans in the nine years' warfare conducted by the Hessianic attorneys should now be able to view the record without prejudice and with perfect fairness.

Electricity has been from the beginning upon the side of the independent companies in their efforts to maintain their businesses. We have not, however, up to this time, ever offered one word of criticism as to the validity of the Edison patent, because we did not deem it politic to do so.

But now the smoke of battle has cleared away and unbiased history can and will be written. We record it as our fixed opinion that the **Edison lamp patent was a fraud from the date when application was made therefor to the time of its judicial limitation by the United States Supreme Court.**

The fraud was first upon the investors who purchased stock in the Edison Electric Light Company, and afterwards upon the public, upon the courts, and upon the competing lamp makers.

We place this opinion on file, of course, with all due respect to the various judges who have decided various points in the litigation and without questioning their honesty. But no electrical man, familiar with the art and with the quality of the electrical knowledge displayed by these judges in their opinions, can allow their conclusions to weigh for anything whatever against the plain records of the progress of the art.

Every worker in the field previous to and contemporaneous with Edison has devout partisan upholders, each of whom puts forth strong arguments for precedence in support of his favorite. All, however, who are familiar with the development of the incandescent lamp (save those who from motives of pecuniary benefit, direct or indirect, were induced to smother their honest convictions) AGREE that the commercial lamp *was* a development, a growth, to which several workers contributed, and that the full measure of credit for the so-called "invention" could not be claimed by any one man; that no man's claim was strong enough to entitle him morally to go down in history as the inventor of the incandescent lamp.

To offer severe criticism of a man who has done so much good work as has Mr. Edison may seem like heresy; but truth will prevail, is now indeed gaining in the struggle against falsehood, and the Edison which our children read of will not be the Edison portrayed in the New York *Herald* in the early eighties and written about by brainless space-writers ever since.

If we search for the one controlling reason why so many judges were found to sustain the unjust claims to priority for Edison, we find it in the continued newspaper twaddle of the period from 1879 to 1885, by which the average reader was convinced beyond any further argument that Edison was the first man in the world who knew anything of the practical application of the electric current. Men who had never heard the name of Faraday, or Siemens, or Starr, or Swan, were made familiar with Edison, "the wizard," through countless articles which the latter's agents either wrote or inspired. So much for the power of the press when exerted in the wrong direction.

If, then, we ask why so many men of education, and of at least ordinary commercial honor, were found ready to engage in the lamp business in the face of the Edisonian claims to exclusive right, we find the answer in the fact that a vast majority of those who were well informed did not believe in the justice of those claims.

Electricity does not assume in this brief article to give credit to every individual who contributed something to the development of the incandescent lamp of to-day. We merely mention four conspicuous workers in the field whose work was as well known in 1879 as it is to-day to the men who were leaders in the art at that period.

Fully entitled to stand at the head as the father of the incandescent lamp was J. W. Starr, an American, whose work in 1845 shows that he had at least discovered all the requisites for a successful lamp.

Passing by the patient workers of the intervening period, many of whom made important steps in advance, and considering the period from 1876 to 1879, history will eventually show that Edison, Swan, Lane-Fox and Weston were all entitled to a fair measure of credit for the working out of the problem, and that no one of the group was entitled to a monopoly of that branch of the art. It will further be shown, we are confident, that the cause of the Edison-Swan compromise in England was the knowledge of both parties that if they fought to a finish it would result in throwing the manufacture of incandescent lamps open to the public at that time.

Judge Wallace came very near to expressing the honest expert opinion when he spoke in his decision of 1891 of the "shadowy demarkation of the line between the essential and non-essential features of the invention."

We hold, therefore, that the independent lamp makers have at no time been infringers in the popular acceptance of the word. They have at no time broken the law of business honesty. They have engaged in a business in which they believed they had a right to engage, backed in that belief by a majority of the men in the electrical line.

The duty of the public, both to themselves and to those to whose courage and persistence is due the reduction of the price of incandescent lamps from $1 to 25 cents, is clear. Other things equal, no man should buy lamps except of one of the many reputable independent lamp companies. This is a debt which the public owes to independence and the true American spirit, and which can be paid with profit to both parties.

The Edison lamp interests have no claims upon the public. For years they charged an extortionate price for their product, retarding as far as they were able the progress of the industry. At the same time they offered a lamp of inferior quality, a lamp which was beyond question the poorest lamp ever offered to the public by a concern of any standing. They never improved the quality of their lamps until forced to do so by the competition of the independent concerns. Again we cite the words of Judge Wallace:

> "Undoubtedly the improvements that have been made in the art, such for instance as the method of electrical carbonization of the filament, since Mr. Edison's invention, have been of great value, and the perfected commercial lamp of to day is far superior to the one which could be made by applying to the description of the patent all the knowledge and skill then possessed by those to whom it was more particularly addressed."

Pages could be written showing just why the Edison lamp patent was unworthy of the respect ordinarily due to the claims of a reputable inventor, and many pages will yet be so written. The history of the litigation is one not pleasant to discuss, but which justice demands must be discussed. It was blackened by the perjury of men like Walter K. Freeman, who testified first on one side and then on the other, and by the concealment of the truth on the part of many an expert who now regrets his connection with it and who hopes the Searchlight of Electricity will never turn in his direction.

The independent lamp makers have not been morally infringers; they have not sought to break down an honest patent, or to rob any worthy inventor of the fruits of his labors. They are as worthy of respect as any class of men in any line of business. They are offering the best incandescent lamps to be bought anywhere in the world to-day, and they are worthy of the confidence and patronage of the public.

* * *

The decision in the Bate Refrigerator case has encouraged the organization of a new cheap telephone company in Washington with metallic circuit free from induction. The Government has constructed a telephone system in the Interior Department for which the entire cost is less than one year's rent of the old plant.

The decision of the U. S. Supreme Court in the McKeesport case will not be handed down before March 25.

Coal Consumption in Central Stations. There is probably no line of work in which the National Electric Light Association can engage that will be more prolific of good results to the lighting industry as a whole than that which has been delegated to the Committee on Data. The difficulties with which a committee having the collection of such information in hand must contend can only be appreciated by those who have had experience in this same work. Members of the present committee have complained of an apathy on the part of Central Station men and an unwillingness on their part to co operate, but while there may have been some apathy, it has doubtless been true that inability rather than an unwillingness has prevented the majority of those who have remained silent from assisting in this most praiseworthy work. This became evident at the Cleveland Convention by the demand for information from Central Station men as to how to prepare or collate the information desired, and we are glad that instructions that will assist those who need them are to be prepared and distributed with future requests for information.

The value of these reports of the Committee on Data, incomplete as they are, is becoming more and more appreciated, and with this better understanding of their value will also come a greater readiness to co-operate as well as a better ability to do so.

We remember distinctly the shock with which the Washington report of this committee was received. Everyone was surprised at the unfavorable showing made, and the committee itself in comparing the results obtained in the Chelsea Jute Mills, of Brooklyn, N. Y., which, during a period of six days, averaged 653.3 indicated H. P. on a coal consumption of 1.482 lbs. per I. H. P., with results obtained in electric light stations in which the best was only half as good, and in which the average reporting was between one-fourth and one-fifth as good, seemed reluctant to believe that its figures were accurate.

A comparison with foreign practice showed, however, that bad as was the showing made by the report, we were in no sense behind. This was a poor satisfaction, however, and has stimulated Central Station managers to do better. In the last report, published in this issue, the best statement far surpasses anything previously given and if the figures are correct probably makes a a record for Central Station economy which has not been previously obtained. This record was an electrical H. P. hour on a consumption of 2.84 lbs. of coal. The second best was 4 lbs., or about the same as the second best in the Washington report. The average of the ten reports from stations generating over 5,000,000 watts per day is stated as 4 lbs. This is evidently a typographical error since we figure it out as 5 lbs. In the Washington report there were but two stations reporting over 5,000,000 watt hours, and these average 4.2 lbs. The average of thirteen stations having an output of 1,000,000 watt hours or more was 5.6 lbs. as against 5.7 lbs. in the last report as an average of sixteen stations.

On the whole, therefore, the Cleveland report does not show quite as good an economy as did the Washington report, and this becomes emphasized when we understand that the stations from which data were obtained for the Cleveland report averaged a very much larger output than did those considered in the Washington report.

When we compare the economy of the Chelsea Jute Mills of producing an indicated H. P. hour on a consumption of 1.482 lbs. or an equivalent of an electrical H. P. hour on a consumption of 1.83 lbs. with an average from our large Central Stations of 5.7 lbs. we see how wide a chance there is for improvement, and it is to be hoped that these reports will be the means of effecting a marked change for the better in Central Station practice.

The Best System Will Win. The N. Y., New Haven and Hartford Railroad Company, which has had the passenger and freight business of a large part of New England in its grasp for several years, is now making a stupid but bitter fight against the electric systems connecting the towns along its various lines. The corporation has taken the matter before the Legislature with a view to ending the increasing inroads of the trolley systems upon its local traffic. The main contention is that public necessity does not demand these trolley roads, and that the State guaranteed in the steam road's charter against parallel lines.

Public necessity demands the best and cheapest means of traffic available, and we don't believe that even the Connecticut Legislature, a large percentage of whose members have shown in times past that they are the servants of the New Haven road, will dare to block the wheels of progress.

If the people want the trolley roads, they will get them. If they don't want them, capitalists will not build them.

Under the Searchlight.

Views and Opinions on Timely Topics.

POLITICS IN CHICAGO.

Are Hornsby and His Pupils to be Provided For?

An ordinance has been introduced in the Chicago City Council providing for the creation of a Board of Electrical Examiners, three in number, who shall be entitled to receive a salary of $500 a year and an allowance of $1,500 for a secretary. It shall be their duty to examine all applicants for the licenses which shall hereafter be necessary to enable any person to engage in electrical construction work or to serve as dynamo tender.

So far, good.

There shall be for the first class an examination fee of $10 and an annual fee of $50; for the second class an examination fee of $5 and an annual license fee of $5.

This Board shall be subsidiary to the Superintendent of City Telegraph, who shall handle the money and issue the licenses.

There is no provision that members of the Board may not hold a dozen other positions at the same time—such as organizers for the National School of Electricity.

It is also provided that—

The Board of Electrical Examiners may in lieu of examination of applicants as to electrical knowledge, for both forms of license as provided in this ordinance, *accept a certificate of graduation or scholarship from such technical schools or colleges as they may regard as expressive of proper qualification for the holders of same.*

Thus the guarantees or promises of Hornsby that pupils of the National School may be able to secure good paying positions as electricians upon completion of a six months' course may perhaps be fulfilled.

Ruinous fines are proposed for those who break the rules laid down by the Superintendent of City Telegraph, and construction companies must file a bond of $300 to indemnify the city of Chicago against defective work.

With Barrett at the head of the inspection department and Hornsby appointed to a place on the Board of Examiners, the electrical interests of the great city of Chicago would certainly be well watched, and the name of Hornsby alone should be sufficient guarantee that all work will be done in accordance with the most advanced ideas. Indeed the Board of Underwriters might then dispense altogether with their inspection machinery!

Who says Professor Barrett and Doctor Hornsby of Heidelberg College, Tiffin, O., are not up to snuff?

* * *

ELECTRICITY acknowledges with proper gratefulness the gift of a package of lead pencils from the *Electrical Review*.

* * *

IT is announced that the final loss of the Edison lamp patent will not itself be included in the reductions in the patent assets in the next annual statement of the G. E. Company, as the decision of the U. S. Supreme Court was not rendered during the fiscal year ended January 31.

* * *

THERE is on foot a scheme for a consolidation in the electrical manufacturing line so comprehensive in its nature as to throw into the shade the rosiest plans of the G. E. promoters even in their few weeks of glory. No intelligent opinion can yet be expressed as to the effects of the proposed plan upon the trade as a whole. It may be for the best. If it should, however, be carried to completion and develop into a second campaign of extermination, ELECTRICITY will be found expressing the same views as heretofore, not intimidated by the wealth or prestige of any body of men in America—not even the Standard Oil coterie.

FISH vs. THE U. S. SUPREME COURT.

The Bate Case Decision.

F. P. Fish says: "The decision construes the statute contrary to the intention of Congress, and was forced upon the Court by the bungling language of the law."

The U. S. Supreme Court said, without a dissenting opinion: "In our judgment the language is so plain and unambiguous that a refusal to recognize its natural meaning would be justly regarded as indicating a purpose to change the law by judicial action based upon the supposed policy of Congress."

New York Electrical Society.

On Thursday evening, March 7, the New York Electrical Society held its regular monthly meeting at the School of Mines. The feature of the evening was a paper by Mr. Charles S. Bradley, of the Fort Wayne Electric Corporation, on "Alternating Currents in their Relation to Distribution of Energy." Mr. Bradley is one of the acknowledged authorities on the subject with which he dealt, and anything which he has to say is listened to with the closest attention and respect. He began by reviewing the history of alternating current development from the single-phase up to the two and three-phased methods, including the so-called monocyclic. As regards the rotary field or drehstrom method, he placed the credit for the invention several steps in advance of Tesla. In fact, he placed Tesla's discovery in point of time the last of several, Marcel Desprez being credited with the original discovery. He also read a translation from the French of a letter describing Desprez's invention, and exhibited a working model of the motor which was actuated by two distinct coils in which the phases differed by 90 degrees and which were themselves at right angles.

As to the relative merits of the various methods of transmission by alternating currents, he classed them in the following order:

For transmission purposes purely—1, tri-phase; 2, two-phase; 3, single-phase.

For lighting purposes he reversed the order thus—1, single-phase; 2, two-phase; 3, tri-phase.

In regard to the so-called monocyclic system he claimed that it was weak in the very point for which its friends had claimed that it was strongest, viz., in its adaptation to motor work. Its weakness in this consisted in the fact that in the motor the phases were not in the best relation. This view evidently coincided with Mr. Scott's, which was that it was "lopsided."

He then showed a three-phased motor of his own invention which had an armature of the squirrel-cage type. This was in duplicate—one half of it consisting of bars of high resisting german-silver short circuited upon themselves, and the other half consisting of similar bars of copper. There was but a single set of field magnets, which, in the motor exhibited, were placed over the german-silver end of the armature in starting and then shifted to the copper end when full speed was attained. He explained that the extra resistance required for starting might be placed externally to the armature and thrown in and out when desired, thus doing away with the double armature and the shifting of the field frames. He also showed by means of a spring balance the difference in starting torque when the fields were placed first over the german-silver winding and second over the copper winding. In the first case the pull at the end of a two foot radius was 2½ lbs. and in the second case 1 lb.

A large number of curves were exhibited showing the performance of the motor and its various peculiarities. One of the most noteworthy of these latter was a series of curves showing the efficiencies of two motors otherwise similar but in one of which the armature was of solid and the other of the usual laminated iron. These curves showed that the efficiencies were almost exactly the same.

The paper proved of great interest to all those present and was charming from its unconventionality. Usually when one sits down to hear a paper on alternating current distribution it is with the expectation of hearing a technical dissertation which it would require weeks to digest. Mr. Bradley, however, used no language which could not be assimilated at once by the merest tyro. In fact his methods of reasoning are exceedingly simple, and this was admirably illustrated by his reply to a question from Dr. Emery. Mr. Bradley had stated that the three-phased motor which he exhibited was a four-pole machine. Dr. Emery asked him how he got a four-pole field with three wires, and requested him to give a diagram of the windings. Mr. Bradley with a loud laugh, and holding his hands up in holy horror, replied that he never made drawings of his windings—that when he wanted to make a machine he "just went to work and *made* it."

Storage of Energy Essential to Economy of Working in Central Stations*—II.

BY N. W. PERRY, E. M.

GAS STORAGE AND GAS ENGINES.

On purely theoretical grounds at least the gas engine deserves our consideration at this point for the following reasons: In the first place, we may replace the wasteful standby losses of steam boilers under the variable central station load by the ideally simple and economical system of gas storage. The use of the gas engine, therefore, comes legitimately within the province of this paper, since it permits of employing a substitute for the boilers, which may be operated continuously at the most economical load, and yet supply with equal efficiency the most variable load that can possibly be thrown upon it.

Comparing the relative theoretical advantages of the gas engine and the steam engine, Prof. Kennedy states that the maximum theoretical efficiency of the steam engine is thirty per cent. Its obtained efficiency is about ten per cent. The theoretical maximum efficiency of the gas engine is eighty per cent. Its efficiency obtained in practice is twenty-five per cent. These facts have led Mr. Thwaite to say that the practical efficiency of the gas engine is equal to the theoretical efficiency of the steam engine. As a matter of general experience, however, under usual working conditions with large engines, very little if any advantage in efficiency is shown by the gas engine over that driven by steam, but if this statement is disputed, as I am not at all sure that it cannot be successfully, the burden of proof lies with the gas engine.

The gas engine has the practical advantage that it may be started and stopped when required, thereby avoiding the standby losses so fatal to economy where boilers are used. These standby losses for boilers are given by Dowson† as ten per cent.; that is to say that boilers that are standing idle and furnishing no steam will require ten per cent. of the fuel they will take when working at their rated capacity. The gas plant, however, where gas storage is employed, has no standby losses of this kind, but in many cases where fuel gas is manufactured to be used on the premises adequate storage is not provided and in times of light load part of the plant is banked. Under these conditions, Dowson states that the standby losses will not exceed 2.8 per cent. The advantages in favor of the gas engine in this respect, even under the most unfavorable circumstances, are therefore as 10 to 2.8 or 3.

As to fuel consumption in gas engines, foreign practice furnishes considerable data. Messrs. Crossly guarantee one brake horse-power hour on a consumption of one pound of anthracite coal, using Dowson gas. Under test conditions‡ the gas engine plant at Chateau Say, supplying 650 lamps, consumed 1.2 pounds per indicated horse-power hour. At Leven Tweed Mills, four gas engines, aggregating 200 horse-power, used in six days' trial one and one-quarter pounds anthracite per brake horse-power hour, or one and three-quarters pounds gas coke per brake horse-power hour. At the Godalming mills gas engines, aggregating 400 indicated horse-power, averaged one pound of fuel (character not stated) per indicated horse-power. At the Chelsea flour mill a sixty nominal horse-power twin cylinder gas engine with Dowson gas, under full load test, used 0.87 pounds coal per indicated horse-power. But, as we are all aware, the fuel consumption under test conditions is no criterion to judge by, and especially misleading when we have under consideration an electric lighting plant. Furthermore, as I think has been conclusively shown, the fuel is by no means the only expense attending the production of power. Mr. Dowson places the cost of a Dowson gas plant of eighty horse-power at $20.31 per horse-power, and for a plant large enough to supply 530 horse-power at $10.87 per horse-power. The wages of firemen for a gas plant are no more than for a steam plant and a much cheaper fuel may be used. But let us assume that the fuel in both cases costs the same per ton, that the gas plant costs $20 instead of $10, so as to cover the cost of extra land required. Then our account would stand something like this:

Cost of engines, 6.17 at $50	$308.50	
Cost of gas plant, 1.547 at $20	30.94	
Cost of buildings	120.00	
Cost of dynamos	120.00	
Total fixed investment	$579.44	
Interest on $579.44 at 4 per cent.	$23.18	
Maintenance and depreciation—		
Machinery,$459.44	34.06	
Buildings, $120 at 2 per cent.	2.40	
Total fixed annual cost		$59.64
Cost of coal, 2 pounds, 8,760 hours, at $1.75	$15.33	
Cost of petty stores	1.64	
Cost of driving, stoking and cleaning	11.67	28.64
Total annual cost per electric horse-power		$88.28
With coal at $3.50 the total cost.		$103.61

Saving over present methods, with coal at $1.75 = $117.78 — $88.28 = $29.50; with coal at $3.50 = $148.40 — $103.61 = $44.79.

THERMAL STORAGE.

Mr. Druitt Halpin, of England, has devised a method of thermal storage which has attracted wide attention abroad and is likely to attract great attention in this country as soon as its efficiency becomes better understood. We all know that a boiler when supplying an intermittent demand is capable of supplying for a short time energy at a much more rapid rate than its steaming capacity would warrant; that during the period of light load it has stored up a certain amount of energy which it can give out again when called upon to do so. It will have been observed that during the period of comparative rest the pressure in the boiler will have increased as also the temperature of the water and steam. It is this increase of temperature that constitutes the storage of energy, and with the same increase of temperature above the normal working temperature the amount of energy stored will be proportional to the quantity of water heated. Since the quantity of water usually employed in our boilers is comparatively small, the storage of energy in them within the limits of safe pressure is, therefore, limited. Mr. Halpin, however, has conceived the plan of connecting the boilers to large iron storage tanks filled with water which is brought to the same temperature and pressure as the boiler. It is a condition any system of heat storage for central stations that the energy stored should be recoverable whenever and at any rate of supply required. Superheated water fulfils this condition, for if the pressure is reduced steam is generated instantly and in controllable amount. This has given rise to three methods of procedure, which he has designated respectively "steam storage," "feed storage" and "combined feed and steam storage."

---

*Read before the National Electric Light Association at its Eighteenth Convention, held at Cleveland, O., February 19, 20 and 21, 1895.

† "Gas Power," a paper by Emerson Dowson in the *Engineering Review*, November 30 and December 20, 1894.

‡ Bryan Donkin, before Incorporated Institute of Gas Engineers.

The first of these was very fully described by Prof. George Forbes at the St. Louis Convention. The other two are later developments.

In the steam storage system Mr. Halpin employs only sufficient boilers to supply the mean demand and storage tanks sufficient to supply the maximum demand. These latter not being subjected to the fire will suffer but little deterioration, and being simple iron reservoirs of sufficient strength to withstand the pressures required are comparatively inexpensive to install. The boilers working continuously at their most economical rate have their excess of energy during light load stored up in the water of the tank, from which it may be drawn at will during heavy load. He proposes that the boilers and tanks shall work under a pressure of 265 pounds per square inch when fully charged, which corresponds to a temperature of 406 degrees Fahrenheit. He proposes that the engines be worked at 130 pounds per square inch, which corresponds to 347 degrees Fahrenheit. The total available heat stored when the reservoirs are fully charged is the difference of the total heat of the water at 406 degrees and at 347 degrees Fahrenheit, or that due to a range of temperature of fifty-nine degrees. Every pound of water falling in temperature through that range will yield sixty-one thermal units of heat. The total heat required to generate a pound of steam at 130 pounds per square inch from water at 347 degrees is 868.8 thermal units. Consequently fourteen and one-quarter pounds of water falling in temperature from 407 degrees to 347 degrees will yield one pound of steam. To allow for radiation loss and imperfect working, this may be taken at sixteen pounds of water per pound of steam. The steam consumption per effective horse-power may be taken at eighteen pounds per hour in condensing and twenty-five pounds per hour in non-condensing engines. The storage room per effective horse-power by this method would, therefore, be $\frac{16 \times 18}{62.5} = 4.06$ cubic feet for condensing and $\frac{16 \times 25}{62.5} = 6.4$ cubic feet for non-condensing engines.

Gas storage, assuming that illuminating gas is used, would require about 20 cubic feet of storage room per effective horse-power stored, and if ordinary fuel gas were stored it would require about four times this capacity.

In water storage 317 cubic feet would be required at an elevation of 100 feet to store one horse-power hour, so that we see that of the three methods of storing energy the thermal method is by far the most economical of space.

In the steam storage method the boiler is completely filled with water and the storage tank nearly so. The two are in free communication by means of pipes, and a constant circulation of water is maintained between the two, but the steam for the engines is taken only from the top of the storage tank through a reducing valve.

In the feed storage system the excess of energy during light load is stored in the tanks as before, but the boilers are not completely filled. In this system the steam is taken exclusively from the boilers, the superheated water of the storage tanks being used during heavy load as feed water to the boilers.

The third method, as the name would imply, is a combination of these two. In the "combined" feed and steam storage system the pressure in boiler and storage tank is equalized by connecting the steam spaces in both by pipe, and the steam for the engines is, therefore, taken from both. In other words, they work in parallel.

An incidental advantage of thermal storage is the purity of water supplied to the boilers. Since the latter derive their feed water from the hot reservoirs, it will have deposited its impurities where they can do no harm. The only unavoidable losses that need be considered in connection with thermal storage are those due to radiation from the reservoirs. This can be provided against by proper lagging so as to be insignificant, and be still further reduced if there be a number of reservoirs. If, for instance, there are four, each will radiate from three-quarters of its surface towards the other three, and only from one-quarter of its surface into space.

STEAM STORAGE SYSTEM.

As illustrating the *modus operandi* and cost of the system of "steam storage," as it is called, I quote from a report by Mr. Wm. Schonheyder, who, taking the load line of the Berlin electric lighting station as a basis, has figured out the relative costs of operation with and without a steam storage system. Fig. 1 is the load line of this station for December, 1891. The scale of the diagram is 1,250 kilowatts per ½ inch, and the water consumption is taken at twenty-two pounds per kilowatt hour. Using storage tanks 8 feet in diameter this would give a scale for water consumption of one inch to 27,500 pounds per hour. The maximum load is 7,500 kilowatts, requiring, say, 10,000 electrical horse-power. The minimum load, according to the curve, is 320 kilowatts, and the proportion of the maximum to minimum work required from the boilers will be as 7,500 to 320 or as 23.4 to 1. The mean load was 2,030. Excess of maximum above mean, 5,080, or a load factor of about 27 per cent. Duration of maximum above mean, 7.5 hours.

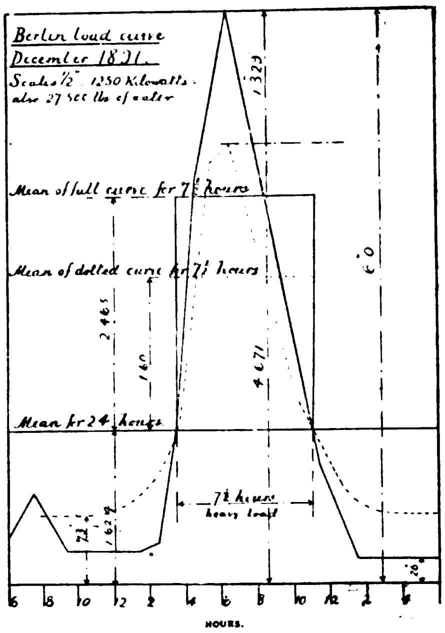

Fig. 1.

In estimating for the steam storage system the extra quantity of steam wanted during seven and one-half hours, and which has to be produced from the water in the tanks, is represented by the area inside the full line curve, Fig. 1, and the straight mean line for twenty-four hours. The boilers and tanks will, under this system, have to work at 250 pounds gauge pressure, equal to 265 pounds absolute, for a large portion of the twenty-four hours. This extra steam, then, is 2.465 × 27,500 pounds × 7½ hours = 508,200 pounds at 130 pounds absolute pressure as required by the engines, and this is equal to an expenditure of 508,200 pounds × (1.219° — 376°) = 428,413,000 heat units,—376° being the mean temperature of the water from which the steam is produced, viz., 406° at beginning of heavy load and 347° at the finish; 1.219° is the total heat of 130 pounds steam. Since the water in the tanks, in producing this steam, cools from 406° to 347° it gives up, say, 59 heat units per pound, and we shall therefore require $\frac{428,413,000}{59} = 7,261,000$ pounds water in the tanks. Taking the tanks, as before, as holding an available (steam room required at top) 75,000 lbs. each, we want $\frac{7,261,000}{75,000} = 97$ tanks.

The necessary boiler power, compared to that of the present installation, will be in proportion of 1.624 to 6, and allowing, say, 5 per cent. extra cost for the increase in pressure, we get the cost of boiler plant with steam storage tanks equal to

Boilers, $\frac{1.624}{6} \times$ £30,000 × 1.05 = £8,526
Tanks, 97 × £500 × 1.05 = 50,925
Total.............................. £59,451

This is nearly double the cost of the existing plant, but, as we will see later, the saving in fuel and in other ways makes the increased investment pay when fuel is dear.

(*To be continued.*)

Thawing by Electricity.*

Mr. Edmunds states that he has been making some experiments lately with most complete success, in what we think is a new and important application of electricity to domestic use. He, like many others, has suffered the inconvenience of having his gas and water service frozen during the late severe weather. It occurred to him that a resistance, suitably protected, might be introduced into those pipes which were most exposed and least easy of access with flame or hot water or other ordinary method of thawing. He had a special wire made, in which the current was conducted through a highly resistant metal, insulated with a fireproof medium that was also a non-conductor of electricity. The whole was enclosed in a metal tube, which could be drawn down to make a compact wire or tube that was externally a conductor of heat, but not of electricity, thus preventing loss of current and electrolysis. The results were most satisfactory This "thermic" wire was introduced into the waste pipe from a bath room at the north side of his house, which entered a fall pipe some 20 feet from the ground, and which was easily frozen. On Saturday last the thermic wire was introduced from the outside. At night a small stream of water trickling down, froze, forming an icicle some 12 inch. long and 1½ inch. thick, completely blocking the waste pipe. The thermic wire having been previously connected with Mr. Edmunds's electric light circuit, at 50 volts pressure, when current was turned on four amperes flowed through it; and in four minutes a complete thawing was effected, and the waste service was cleared. This is a method of thawing which might be worth the consideration of gas and water companies; certainly it is one that highly merits the attention of prudent householders.

An electric trolley tricycle is being built at San José, Cal., to be used to pace bicycle record breakers. It is the invention of Wilbur J. Edwards, the well known racing man, who was the Pacific Coast champion of two years ago. The object of the invention is to provide a mechanism which is especially adapted as a pacemaker to be used in trials of speed for bicycles in connection with that of wind-break or shield which will protect the rider from the resistance caused either by the direct wind blowing against him or the current formed by his own rapid speed.

NOTES ON RECENT ELECTRICAL ENGINEERING DEVELOPMENTS IN FRANCE AND ENGLAND*—II.

IMPORTANCE OF THE LOAD FACTOR IN CENTRAL STATIONS.

All central station people have known for years that the most profitable consumers were those who used their lamps for the greatest number of hours.

In other words, that the net profit due to a consumer was largely dependent upon the relation between his average load and his maximum load, which Mr. Crompton in England has aptly called the "load factor." Yet, while appreciating this fact, central station companies make their rates dependent upon the kilowatt hours used, and independent of the maximum kilowatts used.

Mr. Arthur Wright, at Brighton in England, deserves the credit, as far as I know, for having first given commercial recognition to this load factor of the consumer. Mr. Wright supplies each consumer not only with a meter which registers the kilowatt hours used, but also a second meter of simple construction which registers the maximum kilowatts used at any time during the month, and the discount which the consumer gets is very largely due to the relation between his average and his maximum kilowatts.

Suppose that there are two customers connected to a central station and that the monthly readings show that each has used 900 kilowatt hours. By the usual practice in this country the bill would be the same, yet one bill may be due to the use of one and one quarter kilowatts for twenty four hours per day and for thirty days per month, and the second bill may be due to the use of 30 kilowatts an average of one hour per day for thirty days per month. That is, the first bill may be due to a steady load, such as a few lamps in a basement of a hotel or a ventilating fan, while the second bill may be due to a larger load of lamps used only occasionally, as in an office building or an electric elevator requiring 30 K. W. for a few seconds to start it up, and after starting requiring only 15 K. W.

With the same 900 K. W. hours per month for the two cases, the central station company should charge at least five times as much for the case having the elevator and small load factor as in the other case.

It is a fact not generally appreciated that in any central station the cost of producing a kilowatt hour can be divided into two portions, one of which, such as interest on cost, depreciation, salaries, a small part of the labor and coal, vary with the kilowatt capacity of the plant, that is proportionally to the maximum load, and are independent of the number of kilowatt hours produced, and the other portion of the cost of producing 1 K. W. hour represented by the larger portion of the coal, labor, water, etc., is dependent upon the number of kilowatt hours produced, and is independent of the maximum load.

The fact about this matter which is least appreciated is, that the portion of the total cost of 1 K. W hour produced, which depends upon the maximum load, is about two-thirds of the total cost, and the part dependent upon the output is only about one-third.

In a modern central station 1 K. W. of its capacity represents about $800 invested. Consider the two consumers cited above. Both loads are in use at the time of maximum daily load. For the elevator, the central station has to provide an investment of $9,000, for the ventilating fan $875. Assuming interest, depreciation and similar charges at 10 per cent., we have $900 to deduct from our gross earnings in the elevator case before we reach net profits, and $87.50 in the other case.

Suppose we get 10 cents per kilowatt hour in each case, and that the cost of production independent of general expenses, interest, depreciation, etc., is 50 per cent. of the gross receipts, etc. This would mean that if we get 10 cents for each kilowatt hour in both cases our gross revenue would be $90 per month in each case, and gross profit $45 per month, or $540 per year, in each case. But in the elevator case we have interest and depreciation charges of $900 a year, and hence have actually lost considerable money in supplying this customer, while in the other case we have made a net profit of over $500 per annum.

We would have to charge more than ten times the rate per kilowatt hour to the elevator that we charge to the ventilating fan to make the same net profit on $1 of capital invested.

This load factor is a most vital question, and it is the difference in load factors in English and American central stations which makes storage batteries commercially possible there and impossible here.

The average load factor of an English central station is less than 15 per cent., and even in London in December it is only 33 per cent., while in most American cities the load factor which averages 40 per cent. will in December in many cases be above 50 per cent.

This difference is due almost wholly to our motor load, which is an almost unknown quantity abroad. With a 15 per cent. load factor a storage battery may pay, but not with a load factor of 40 per cent., especially when the load factor in our central stations is rising each year.

If central station companies would offer such a discount due to load factor as to warrant an individual customer's installing at his own expense a storage plant which he would charge at the minimum rate per kilowatt hour by a steady current for twenty-four hours per day, and then used this stored energy to supply his occasional demands for an occasionally very large rate of energy, I believe it is possible that the central station companies, the storage battery companies and the consumers might all derive a profit from the arrangement. I have no doubt that a central station company could afford to make a rate of 4 cents per kilowatt hour for a continuous service night and day, and make a satisfactory profit, while it would surely lose money in supplying an elevator, such as described above, even at 15 cents per kilowatt hour.

I believe that the following schedule of rates fairly represents the charges per kilowatt hour that should be made to customers of various load factors:

Load Factor.	Rate per K. W. hour in cents.	Resultant gross income per annum per K.W. of plant.
5	30	$131.40
10	20	175.20
15	16	210.24
20	13	227.76
25	11.2	245.28
30	10	262 80
35	9.2	281.07
40	8.5	297.84
50	7	306.60
60	6	315.36
70	5.3	325.00
80	4 8	336.38
90	4.4	346.89
100	4	350.40

THE HEILMANN LOCOMOTIVE.

In France I examined what I considered the most important electrical engineering development of all that I saw. It was the Heilmann electric locomotive.

The locomotive I saw was the first one built, and was not in service when I was there. It had run 2,200 miles commercially, however, and as a result of the performance of this first locomotive which was 600 H. P., there are now building two locomotives of 1,500 H. P. each, which it is expected will go into commercial service about June next.

The entire weight of the locomotive is 114 long tons; that is, about 15,500 pounds per driving wheel, which is about the same as our standard practice in this country. With a tractive coefficient of .2 this means a draw-bar pull of 50,000 pounds, and assuming friction at six pounds per ton, we find that 50,000 draw-bar pull would enable us to pull 1,900 tons on a one per cent. grade at a low speed, say 15 miles per hour, and would give us ample draw-bar pull for handling a 200 ton train at any speed thus far seriously discussed.

The steam engine is compound, well-balanced and directly coupled on its shaft is the electric generator. A four-pole single reduction motor of the iron-clad type is geared to each of the eight axles, and the motors, which are series wound, are in multiple with each other across the brushes of the generator armature. As the motor field must have a fair degree of saturation to prevent sparking when the locomotive is running light and pulling no train, it will be evident that under all operating conditions the motor fields are constant and fully saturated, which makes them entirely sparkless. The field of the generator is separately excited by means of a small auxiliary engine and constant potential dynamo, which also supplies the electric lights needed. The main engine has a fixed cut-off at the most economical point, say one-quarter stroke, and its speed is adjusted by the throttle.

The engine in practice is varied in speed from perhaps 50 to 500 revolutions, and the strength of the generator field from zero to its maximum strength. It will be noticed that all steam used is used expansively at a fixed cut-off, and Mr. Heilmann lays great stress on this, although I myself would prefer an automatic engine running at a constant speed, and I believe that he would if he could get as good ones abroad as we can in this country. For starting, an almost unlimited torque is secured by gradually increasing the generator field strength and speed, which sends a current through the motors, rising smoothly from zero to that current sufficient to start the motor armature. If we leave the field controller and throttle in this initial position, our train will start smoothly, and will continue to move slowly, using the full current, but producing the current with about 50 volts or one-tenth of the full voltage, and we will be producing this power, about one-tenth of that required at full speed, by a steam engine using steam expansively instead of, as in the steam locomotive, full stroke. But of course we desire to accelerate the train rapidly, so we keep on manipulating the field controller and throttle, until we finally have the engine driving the generator at full speed in a field of full strength, which will of course represent the full power of the locomotive. When we reach a grade requiring three times the torque required on the level, we weaken the field to one-third of its full strength. We will then move up the grade at about one-third of the speed on the level while using the same power as was required on the level.

It will be noticed that under the electrical arrangement on this locomotive the electric energy is used in such a manner that its voltage is varied in proportion to the speed desired, and the amperes are in proportion to the torque required, so that the electrical energy produced is utilized in the most efficient manner possible.

An electric locomotive of this kind would probably cost for the first few about $80,000, each being equipped with a 1,500-horse-power boiler of our best marine type and one of our best automatic cut-off compound engines directly coupled to a modern multipolar generator. I believe that a locomotive of this type could be built which would be able to pull 50 per cent. more weight than any of the present steam locomotives, and that it could pull the same weight at 50 per cent. higher speed. I think this type of electric locomotive is the stepping-stone between the steam locomotive and the electric locomotive operated from a distant central station.

---

*Abstract of H. Ward Leonard's paper read at a meeting of the A. I. E. E., February 27.

A Method of Determining the Eddy Current and Hysteresis Losses in Direct Current Armatures.

BY A. W. K. PEIRCE.

By running a direct current machine as a motor, unloaded, at its proper speed and degree of magnetization, the input to the motor armature gives a measure of the above losses plus the friction of the bearings, brushes, etc. To eliminate this friction loss, the hysteresis and eddy current loss may be separately determined; the method usually employed is to run the armature at a constant speed in a frame whose magnetizing coils are adapted for separate excitation by means of another machine run as a motor. On measuring the input to the motor at various stages of the magnetization of the driven armature from zero to the maximum desired, the above losses plus the various losses in the motor are found. Assuming that these losses are constant (except the C^2R, which may be calculated and allowed for), the difference between a reading taken at any particular stage of magnetization and that taken at zero magnetization will represent the losses due to eddy currents and hysteresis in the driven armature for that particular magnetization. This magnetization is calculated from the E. M. F. generated in the driven armature as measured by a voltmeter connected to the brushes.

The assumption that these various losses in the driving motor are constant is hardly allowable. It may, if a large motor be used, be such that the difference between the various readings is small; but in this case the liability of error in determining the comparatively small difference between comparatively large readings is great. If a small driving motor be used, the liability of such error is much reduced; but new sources of error appear; the total tension of the driving belt, consequently the pressure on the bearings of both machines, and the amount of the "belt creep" are much increased, and the increased armature reaction of the driving motor causes its field to vary both in distribution and amount, thus varying its internal armature losses.

It is true that these variations may not amount to more than five or six per cent., and an error of this amount in determining a loss which only affects the efficiency of the machine by four or five per cent. is not serious; but the writer has devised a method of making these same measurements in which the sources of error above outlined do not exist, and as it requires as little or less manipulation, presents it as being superior to the method just described. In this method the arrangement of the driving and driven machines is the same as described, except that it is more convenient to use a series motor as the driving machine, although any will do.

The procedure is as follows:

The E. M. F. applied to the driving motor should be varied (by a rheostat connected in series with it) until the speed of the driven armature holds steady at the desired amount, the magnetization of the driven machine being zero. The current and E. M. F. at the terminals of the driving motor are carefully noted; a current is then sent through the magnetizing coils of the driven machine, and the resulting field, by putting extra load on the driving machine, slows it down.

An E. M. F. is now applied to the armature terminals of the *driven* machine slightly greater than and opposite to the E. M. F. generated therein. The obvious result is that a current will flow through the winding of this armature which will tend to drive it as a motor, and the applied E. M. F. may be varied until the current flowing will exert just torque enough to balance the load due to the hysteresis and eddy current losses, leaving the driving motor to furnish the balance of the power required. This will evidently be just exactly the amount it was called upon to furnish when there was no current in the magnetizing coils of the driven machine, and the point at which this condition is reached will be indicated by the return of the speed and the current and E. M. F. of the driving machine to their original values as previously noted.

Under these conditions the input into the driven armature, which should be noted, is equal to the loss in that armature due to the eddy currents and hysteresis at that speed and degree of magnetization plus the C^2R of the armature windings. In a well designed machine this C^2R will prove to be so small that it may be neglected, but it may readily be calculated and subtracted if desired.

The magnetization of the armature may be calculated from its counter E. M. F.; the applied E. M. F. as read is so very nearly the same that its values may be taken.

For any other magnetization the above process would be repeated until a sufficient number of observations are made to allow the core loss curves to be platted.

The advantages of this method over that first given are, that the load on the driving motor and its speed being the same at all readings, its losses of all descriptions are constant. The instruments used to indicate its condition of load need not be accurate, or even calibrated at all, as their readings are necessarily the same; the only accurate instruments required are two, a voltmeter and an ammeter, and the product of their readings gives the desired results directly, or at most only a very slight subtraction (C^2R) is made.

A few hints regarding the making of tests of this general character may be in order.

Never depend for the readings of the speed (revolutions per minute) or any form of speed-counter or similar device which requires a lapse of time for its operation. Always use some form of direct-reading tachometer or other centrifugal indicator, which will give at any instant the *rate* of revolution, as that is what is required, not the number of revolutions which may occur in a given time.

Always wait before reading the other instruments until the revolution-meter indicates not only that the speed is that desired, but that the machine is steadily running at that speed; for if the speed be increasing, the driving machine is furnishing not only the power required to overcome the losses, but in addition is providing the power represented by the *acceleration* of the moving parts; conversely, if the speed is falling, a part of the power required to drive the machines is furnished by the reduction in the velocity of the moving parts, and any readings of the power supplied to the motor will give results too great or too small respectively. This is obvious enough, but is a point very frequently neglected.

When a motor is run with its armature terminals connected directly to the supply mains, the *effective* E. M. F. which is driving the current through the motor armature is only the difference between the E. M. F. of the mains and the counter E. M. F. of the motor armature. Now as this effective E. M. F. is small compared with the total (applied), slight variations, even if not more than 1 per cent. or so of the applied E. M. F., will vary this effective E. M. F., consequently the armature current in a very much greater proportion, especially if the moving parts of the machine have considerable inertia so that their speed does not respond readily to the variation in the motor torque due to the variable current.

On account of the above condition it is often difficult to make accurate readings of the current taken by such a motor.

If this is the case, it is only necessary to increase the E. M. F. of the supply and insert a resistance in the motor armature circuit, so that the drop in the resistance is about the same as the drop through the water; in other words, if the motor is wound for 115 volts, run it on a 230 volt circuit and cut down the E. M. F. on the motor to 115 volts (or whatever is required) by inserting sufficient resistance.

Under these circumstances, the difference between the applied and the counter E. M. F.'s is considerable, and slight variations in the applied E. M. F. have a correspondingly slight effect on the current.

The employment of this plan of steadying the current will often save much time in making tests, and will contribute largely to the accuracy of the results.

It is hoped that the above rather desultory remarks will prove of interest to those who have had occasion to make "core loss" tests, or have attempted to reconcile and use the results of such tests.

Scranton, Pa.

THE WELSBACH LIGHT.

Discussion of This Topic at the Cleveland Convention.

Mr. Gardener—In the city of Pittsfield there are at the present time about 250 of these burners in use. I understand that more have been ordered, but the agent has not been able to supply them. A dentist in North Adams was operating upon a patient under the light of a Welsbach burner, when the lamp exploded and imbedded pieces of glass in his cranium. I immediately investigated the subject, and found that he was no longer using it. We had a customer who was using our lights in his store and workshop, and he substituted the burner in his store but not in the workshop, the reason being that the hammering of his workmen on the benches caused a vibration which would gradually shake the mantel to pieces.

Mr. Edgar—We have had as much experience as any other city, but to sum up a long story I will say that the burner is gradually disappearing. I put one in my house two years ago. At first it saved considerable gas and gave a beautiful light, and the first outfit of mantels lasted over two years. Since that time the mantels have gone to pieces very fast, and my gas bills are larger than they ever were with the old burner and I do not think we are using any more light. We have just completed a contract with a large store which is going to take out the Welsbach and put in our lights. We have a letter from a drug store, stating in emphatic terms what the proprietor thinks of the Welsbach—often when his store door opens the mantel breaks from the draught of cold air. We are naturally prejudiced against the burner and want to see the thing disappear; but, leaving that out of consideration, I should say the burner is losing ground in Boston within the last six months.

Mr. Cairnes—In Memphis we became very much alarmed. They displaced probably 1,500 to 2,000 lights in from 30 to 60 days, and no amount of argument could stop the stream of popular favor in the direction of the Welsbach, and we sat down and mused over the possibilities of an assignment in the near future. That was about a year ago. I presume we have back from 50 to 60 per cent. of the patrons we lost by the burner, and I have assurances that we will get back as much as 25 or 30 per cent. more within the next two months. They have lost ground in Memphis as rapidly as they came in favor.

Mr. Burleigh—For what reason have they lost favor?

Mr. Cairnes—The fact that the longer they are used, the more objectionable the light produced becomes; and in like proportion the greater amount of gas is consumed as the burner begins to be used.

Mr. Seely—I do not think it is a very serious menace to the electric light business where people are at all discriminating as to the character of light they get. In smaller towns people are not as discriminating as they are in larger cities. It seems to me that one of the things the local companies want to do is to maintain better service themselves. One of the reasons that encourage the use of the Welsbach burner is that in some places the service of the electric light companies is irregular.

Mr. Peck—Our station in Brooklyn is almost entirely given to arc lighting. I noticed some four months ago that about 25 large stores used the Welsbach burner. I noticed the same stores a week or two since and discovered that 10 out of the 25 have gone back either to simple gas or the incandescent light.

Mr. Armstrong—This is very encouraging to us. The fact of the matter is that the electric light is a luxurious light, and it will compete, perhaps, with gas in larger quantities, but it will not with the small consumer. That is the thing we must face. The practical difficulty is that it does not pay us to supply very small consumers; it does not pay for the installation, the meter and all that. I am pleased to hear from Memphis and Boston as to what has been the history of this thing; but so far as our incandescent business is concerned it has been and is now a very serious problem. We lost during the last quarter 75 customers, and we do not see any cessation to it. I hope to report by next year that the number has been diminished in accordance with the statements made from other cities.

Mr. Stetson—I know a town a little north of Boston where I heard the manager say if he could have seen the Welsbach burner before he bought his electric light plant—he manages both wings of the service—he never would have troubled himself about the electric light plant, and is only hoping that the municipal lighting scheme would come along and buy his plant. You cannot compete with gas in small towns under 25,000 inhabitants. In the larger cities the electric can hold its own. I find the greatest annoyance in our community to come from the multiplication of the oil wagons. The Standard Oil Company has put up a very large tank holding thousands of barrels of oil, and they run out wagons just as the milk peddler does; and as our cities in the East are largely composed of people working in factories, there is no hope of our trying to get anything out of them with the electric light. If we could only increase our product we could decrease the cost; but there is no hope of this in those communities.

Mr. Corriveau—I do not think there ought to be much alarm felt about this Welsbach burner, or what we call in Montreal the oil light. I do not think there is a city in America which is provided with so many of these burners as Montreal at the present time. They have had them about a year and a half, and several thousand of them are in use; but I am pleased to state that to my personal knowledge eight or ten large stores have gone back to the electric light, and the reason is that they are completely displeased with the burner on account of the breakages of the mantel and the bad color of the light, and I believe it will only be a short time before this will be general.

Mr. Francisco—We had a customer who put in the Welsbacn, and after using it a month returned to the electric light. I asked the reason, and he said I had about 200 of those burners and I wanted to sell them; but I do not propose to lose on my own light the profit made on those burners.

That Allegheny Plant.

New bids have been opened for the lighting plant at Allegheny, Pa. The contract was supposed to be safely awarded to the Western Electric Company, but it seems their bid was defective, not covering the foundations as required by the specifications.

The latest Westinghouse bid is nearly $6,000 below their original bid of $16,385, and the new bid includes foundations, which the original did not. It is also $4,250 below the Western Electric's only bid (of Ball engines) with foundations, $14,500, and $2,750 below the Western's bid, which received the first award, $13,000.

THE NEW YORK BOARD OF FIRE UNDERWRITERS.

On Wednesday, March 6, the Committee on Electricity of the New York Board of Fire Underwriters met at their rooms to discuss the subject of "Attix" wire. The question at issue as to whether the Attix wire should be regarded by the inspectors as a conduit within the intent of the rules of the National Electric Light Association and the Underwriters' Association for Electrical Construction or not. It seems that Prof. Henry Morton had passed upon this wire in the following terms :

STEVENS INSTITUTE OF TECHNOLOGY,
Hoboken, N. J., May 21, 1894.

WM. A. ANDERSON, ESQ.,
Sup't New York Board of Fire Underwriters.

Dear Sir : In reference to the sample of Attix Insulated Wire sent by you April 21, I would report that portions of it have been under test ever since they were received in water, in air saturated with water, and imbedded in plaster.

In no case do they show any deterioration or loss of insulation, the latter being at this time over twenty megohms per mile, which is more than sufficient in practical use.

This insulated wire in my opinion can, therefore, be safely used imbedded in plaster or inclosed in moulding.

Very truly yours, HENRY MORTON.

P. S.—I regard this Attix wire as equally safe with a wire inclosed in the waterproof paper tubes heretofore approved. H. M.

Installations had been made of this wire which according to the letter of the rules did not conform to the requirements and had been rejected by the inspectors of the Bureau of Electrical Inspection, to which organization a number of very prominent insurance companies belong, and they consequently declined to assume the risks. The meeting was called to determine whether or not, within the meaning and intent of the rules, the Attix wire was a conduit. The New York Board of Fire Underwriters, or rather their committee having this subject in charge, held through the endorsement of Prof. Morton that the Attix wire did come within this meaning. The Bureau of Electrical Inspection, through Mr. Geo. W. Hoyt, Deputy Manager of the Liverpool and London and Globe Insurance Company, dissented from this view.

In addition to the Committee on Electricity, there were present by invitation a number of experts, among whom were Prof. Henry Morton, Prof. W. A. Anthony, Edw. H. Johnson and Messrs. Attix, Habirshaw, Stieringer, Godfrey and Perry.

Prof. Morton was first called to the witness chair, and in reply to questions from the president, stated that the Attix tube was a Habirshaw wire covered with a protective covering of braided material which was non-inflammable and afforded a good protection against mechanical abrasion. It would repel moisture, withstand the chemical action of plaster and cement, offered a high insulation resistance, and while it would not repel nails, etc., to the same extent as an armored conduit, was, in his opinion, the equivalent of a conduit, and better in some respects than an armored conduit, in that it did not have a conducting coating. The president of the committee in speaking of the Attix wire had called it a tube and Prof. Morton held that it was a tube—thus endeavoring to bring it within the rules covering the installation of interior conduits. Mr. Hoyt maintained that it was not a tube and hence could not come under this head, and that even if it were regarded as a tube the installations in question did not come within the requirements for conduits, which state that the conduit should be installed first and the wires drawn in afterwards, or come within the meaning of the section which states that "the object of a tube or conduit is to facilitate the insertion or extraction of the conductors."

A member asked Prof. Morton to define the meaning and province of a conduit as provided, but the chair ruled that the committee was better competent to decide this question. Mr. Hoyt, in reply to this ruling, stated that if the committee intended to amend the rules so as to give them an entirely different meaning from that which they now had, he had nothing further to say.

Mr. E. H. Johnson being called upon for some remarks, paid a high tribute to the quality of Attix wire, but claimed that it did not and could not meet the requirements of a conduit. He had been endeavoring for years to improve the quality of interior wiring, and had found that the best he could do was none too good. He differed with Prof. Morton that the metallic armor was in any case a disadvantage. It was in fact a great safeguard, since if a nail penetrated the insulation to the wire it constituted a short circuit which made itself manifest at once instead of remaining a menace to the building forever after until the latter burned down.

Prof. Anthony took very much the same ground, maintaining that the Attix wire was not a conduit—it was not a tube, and did not in any way meet the requirements of a conduit.

Mr. Perry asked Prof. Morton how the Attix wire differed generically from any other wire having more than one insulating layer. The reply was that the outside covering was sufficiently strong to offer great resistance to mechanical abrasion. Mr. Perry then said, "You would then consider any wire that was taped or braided so as to resist mechanical abrasion as a conduit ?" "Yes," said Prof. Morton, "it would in my opinion be equally good."

This question, which is as yet by no means settled, is likely to assume very important proportions before the matter is ended, and both wire manufacturers and underwriters are awaiting the outcome with intense interest.

London Notes.

(From our London Correspondent.)

Propagation of Magnetization Iron.

A brief abstract of the paper by Dr. J. Hopkinson, F. R. S., and E. Wilson, read before the Institution of Electrical Engineers on Feb. 21, is here given :

The paper deals with the same subject as was dealt with by the same authors at a meeting of the Royal Society on May 31, 1894, but the experimental work was carried out with larger apparatus. It has, of course, been long known that in electro-magnets with solid cores currents are induced in the solid iron when the magnetizing current is reversed, and that these currents for a certain time retard the development of changes in induction. The length of time that these currents exist will be surprising to many. In the experiments shown, a magnet of 12 inches diameter was used, and exploring coils were buried in its substance. These showed how the change in induction occurs extremely rapidly near the surface of the magnet, less rapidly at some depths, and slowly at its center. With certain magnetizing forces it takes as much as four minutes before the change at the center of the core attains a maximum. The application of the results to magnets with cores of other sizes was pointed out, and conclusions were drawn as to the appropriateness of general practice in regard to the sizes of wires or plates used in transformers. The experiments were made in part with the reversals of current in the magnetizing coils, and in part with the currents of a slow alternating character. The slow alternating currents were produced by means of a liquid reverser substantially similar to one which was described by Professor Ewing.

N. E. L. A.

Report of the Committee on Data.*

Mr. President:

The information contained in the tabulated report submitted herewith while recording data from fewer places than usual is believed to contain correct information and more than usual detail. Certain classes of equipment are not reported in sufficient numbers to warrant correct averages, but every central station manager will find in the table a style of equipment sufficiently like his own to enable him to compare results with at least a few others who are similarly equipped. The table contains reports from twenty-four stations using coal as fuel. The highest economy is shown in report No. 22, where 262 watts are generated from one pound of coal, the plant furnishing nearly 23,000,000 watts during 24 hours, the equipment being triple expansion engines with dynamo on the engine shaft, and horizontal water tube boilers with heaters, without economizers, the firing being done by hand. This result is secured from one-half each soft coal and hard screenings. An examination of this report proves it to be a high average for 24 hours, as with an evaporation of 9.37 lbs. of water per lb. of combustible, and a water consumption of 17 lbs. per horse-power, allowing 10% non-combustible in the coal, and taking the efficiency of the generators as stated at 85%, we have $\frac{9.37 \times .90}{17} \times 746 \times .85 = 314$ watts produced from one pound of coal. This average is much nearer the theoretical efficiency of a modern steam plant than any report previously received by this committee.

EQUIPMENT.

CLASS A. Boiler Room Horizontal Water-tube boilers feed through heaters by steam or power pump; hand firing. Engine Room Triple Expansion Condensing Engines. Dynamo on Engine Shaft.

CLASS B. Boilers Vertical Water-tube, economizers, feed as A Hand firing. Engines. Corliss Compound Condensing, belted to jack shaft.

CLASS C. Boilers. Horizontal Tubular, feed as A. Engines, Simple Corliss or slow speed, condensing, belted to jack.

CLASS D. Boilers, Upright Tubular, feed as A: Engines, Simple Corliss, Non condensing.

CLASS E. Engine, High Speed Compound Condensing, belted direct.

CLASS F. Engines High Speed Simple Non-condensing, belted direct.

CLASS G. Engines, High speed Compound Non-condensing.

REF. X. Any of the above non condensing.

REF. Y. Belted to dynamo.

REF. Z. Dynamo on the Engine shaft.

Taking an average of the ten reports from stations generating over 5,000,000 watts in 24 hours we have 147.5 watts per lb. of coal, or a production of one electrical horse-power for four lbs. of coal on a basis of the efficiency of the generating machinery as stated in the last report by this committee.

Previous reports by this committee have been criticised as inaccurate and incomplete, and an attempt has been made in the work here submitted to improve it in both these particulars. From the first the results of this work have been handicapped by reports from the central stations incorrect, incomplete and based upon a variety of testing instruments constructed without any absolutely uniform standard. And again many central station managers do not wish to have their work made public, and in order to get at the results secured by these people, the information has previously been furnished to the committee, through your secretary, in such a manner that the committee were relieved of the responsibility of the exact source of the information furnished. This, in a measure, defeats the main object of the work.

. . . A careful review of this work for the past three years reassures this committee that the present method of securing data from central stations by individual effort on the part of the committeemen, with the understanding that the information is to be held confidential, meets all the requirements, as any manager can communicate with the author of any report either through the committee or the secretary of this Association, and reports can be had in this way from many who are not willing to have their work made public. . . . Several members of the present committee were unable to give the matter attention, and the table is therefore made from a limited number of reports. If the succeeding committee could pledge its membership to secure at least twenty-five reports each from the central station managers in their locality a much more valuable report can be made. . . .

H. M. SWETLAND, Chairman.

DISCUSSION.

Mr. W. R. Gardener—I consider a paper of this kind of very great importance to central station managers. In this paper the committee have gotten down to facts—there is no theory or fancy. It is made up of reports received from central stations and is worthy of careful study. The principal items of information given us by the reports are the equipment of the stations represented and the number of watts produced per pound of coal. I think it would be well that the valuable work of this committee be extended so as to give us other items that enter into the cost of developing energy aside from that of coal. To give you an idea of what I mean I will, with your permission, read to you the results of a test that has been made under my direction:

Method of Operation.

The entire coal used during period of test was weighed, including that used for banking. The water was also weighed.

The number of watt hours produced was found by ammeter and voltmeter readings taken as follows:

Single phase alternating current, readings every 30 minutes—watt hours produced	1,983,024
Two phase alternating current, readings every 15 minutes—watt hours produced	1,125,765
Street railroad, readings every 10 minutes—watt hours produced	589,743
Arc lights, readings every 15 minutes—watt hours produced	355,144
300 volt direct current power, readings every 15 minutes—watt hours produced	260.170
Total watt hours produced	4,313,846

Number of hours each class of service was rendered.

Single phase alternating current from 8 A. M. Dec. 27 to 8 A. M. Dec. 28—total run	24 hours
Two phase alternating current from 8 A.M. Dec. 27 to 12:15 m., and from 1 P. M. Dec. 27 to 8 A.M. Dec. 28—total run	23¼ hours

---

*Read at the Cleveland Meeting, February 21, 1895.

Street railroad from 8 A. M. Dec. 27 to 10:30 P. M.,
and from 6 A. M. to 8 A. M. Dec. 28—total run.. 16½ hours
Arc lights were run from 3:45 P. M. Dec. 27 to 6:30
A. M. Dec. 28—total run.............................. 14¾ hours
300 volt direct current power from 8 A. M. Dec.
27 to 6 P. M., and from 7 A. M. to 8 A. M. Dec. 28
—total run.. 10 hours

My object was to find out the ratio of the different items of expense to the whole. The different items entering into the cost of developing energy I will class as follows:

First, which I will call Cost of Steam (coal and water only).

Second, which I will call Cost of Throttle of Engine: The above and wages of firemen, repairs of boilers, interest on boiler room investment, fire and boiler insurance on same, depreciation on boilers, which I have allowed at 5 per cent.

Third, which I will call Cost at the Switchboard: The above and wages of engineers, dynamo tender, mechanic and wiper, repairs electric plant, oil and waste, interest on steam plant, interest on electric plant, interest on real estate, insurance on entire building and contents.

Fourth, which I will call Cost at the Lamp or Motor Without Depreciation: The above and general salaries, office expenses, cost of carbons, globes, insurance, interest, incidental expenses, incandescent lamps, law expenses, oil and waste, re, airs steam, repairs electric, repairs lines, taxes, wages, wiring and wiring supplies.

Fifth, which I will call Cost at the Lamp or Motor Including Depreciation on Total Investment (which I have placed at 5 per cent. This does not include drop in the lines from station to lamp or motor.)

Taking the fifth, Cost at the Lamp or Motor Including Depreciation, as the total cost, I find that the cost of steam is 33.8 per cent. of the whole;

That the Cost at Throttle of Engine is 6.8 per cent. more or 40.6 per cent. of the whole;

That the Cost at the Switchboard is 26.4 per cent. more or 67 per cent. of the whole;

That the Cost at Lamp or Motor Without Depreciation is 15.7 per cent more or 82.7 per cent. of the whole;

That the Cost at the Lamp or Motor Including Depreciation on Investment, but not including any drop in line, is 17.3 per cent. more, or 100 per cent., the original total cost.

PERSONAL.

Robert Burns Corey.

The announcement that Mr. R. B. Corey is again actively engaged in the arc lamp business will be received with pleasure by his many friends who are scattered over the whole country.

The widespread use of arc lamps on incandescent circuits really dates from Mr. Corey's entrance into the electrical field. and to his energy, perhaps, more than to any other single cause is due the conversion of so many central station managers and the general adoption of this method of street lighting in connection with the commercial service of our low-tension stations.

Mr. Corey has had an extended commercial experience, and in his six years' connection with the electrical business has probably built up as wide a circle of acquaintances as any other man in the field.

The new enterprise is a purely individual one and will be conducted under the name of R. B. Corey. With Mr. Corey will be associated Mr. John C. Knight, an arc lamp expert of high attainments, whose latest production in the shape of an arc lamp for incandescent circuits was adopted by the Brooklyn Edison Company, who now have about 1,000 of them in use.

The concern will carry a full line of arc lamps for all services, including plain and ornamental series, direct and alternating current lamps, twin lamps, focussing lamps of every type, photo-engraving lamps, searchlights and complete theatrical outfits.

The popularity of their lamps and the high regard in which the gentlemen are held in the trade are evidenced by the number of orders received before their offices in the Havemeyer Building were really opened for business.

ELECTRICITY voices the sentiments of all good men in wishing them a full measure of success.

AT the April term of the Essex County (N. J.) Court damage suits aggregating $250,000 will be begun against the Consolidated Traction Company. This amount would pay for 5,000 fenders at $50 apiece.

Another Perkins Lamp.

C. G. Perkins, the inventor of the original Perkins lamp, has purchased the factory property at 83 Woodbine street, Hartford, and will shortly begin the manufacture of the Perkins incandescent lamp. Mr. Perkins will employ about 175 hands and will turn out at first 1,500 lamps per day. The factory has 25,000 square feet of floor space.

LECTURES ON ELECTRICITY.

Columbia College.

A course of six lectures on "How Electricity is Now Being Utilized," by Francis B. Crocker, E. M., Ph. D., Professor of Electrical Engineering, Columbia College, will be given in Room 11, Library Building, on successive Thursday evenings at 8:15 o'clock. These lectures will be very fully illustrated by experiments, and are specially intended for professional and business men who desire to obtain an intelligent idea of the present uses of electricity. The dates and subjects are:

March 21—How Electricity is Generated and Stored. March 28—Alternating Currents. April 4—How Electricity is Used for Lighting and Heating. April 11—The Electric Motor and Its Use in Transmission of Power. April 18—Electric Railways. April 25—The Telegraph and Telephone.

Tickets for the course, at $5, may be obtained of the secretary of the President, Columbia College. Tickets will not be sold for single lectures.

[Prof. Crocker has very kindly tendered his services for this course free of charge, and the nominal admission fee will be applied to meeting the necessary expenses of the course.—ED.]

VIEWS OF MR. WESTINGHOUSE.

(From an Interview in the Pittsburg Commercial-Gazette.)

Ever since the formation of the Edison Electric Light Company in 1878, its various managements seem to have acted under the assumption that, through the Edison inventions and certain patents therefor, they would be able to secure a monopoly of the electric light and power industry of the United States on their own terms, ignoring the fact that there were other electric light and power inventions and patents, some of earlier and others of even date, controlled and relied upon by others for the conduct of a competing business. As a consequence, all users of apparatus manufactured by others have been frequently threatened or sued and otherwise put to great expense, so that many electric light and electric railway enterprises have been constantly harassed and retarded, and the public interests correspondingly injured.

Nothing short of the complete control of the electric light industry of the country would satisfy the managers of the General Electric Company. The chief opponent to the carrying out of this policy was the Westinghouse Electric Company, which had become the owner of the Sawyer and Man patents, the Weston, Maxim and others owned or controlled by the United States Electric Light Company, and a very large number of other and recent patents.

The control of one side of the Bate case, just decided by the Supreme Court, was secured by the General Electric Company with the view of having the lower courts reversed as to the interpretation of the law determining the life of American patents. The Westinghouse Electric Company, in self-defence, naturally took the opposite side, and it seems that in such defence it has been successful. The electric lighting patents affected by the Bate decision are the earlier ones relating to the use of continuous currents, and the decision thus affects, besides the General Electric Company, all kinds of lighting, isolated or central station, by means of continuous currents.

The later patents relating to alternate current apparatus, details and systems, are not affected by the decision; and as the Westinghouse Company was the promoter of this system of electric lighting in the United States, and has secured a very large number of early and important patents, it is left in a position of great strength as compared with its competitors, more especially with reference to the distribution of power by means of alternating currents and multiphase or Tesla motors.

Biblier, White & Co. is the title of a new firm having offices in the Hathaway Building in Boston and handling several high grade specialties, including the well known Cerfeld insulated wires, the Cutter switches, etc., etc.

General News.

What is Going on in the Electrical World.

Knoxville, Tenn.—This city proposes to make its own electric lights and will advertise for bids for a plant.

Savannah, Ga.—The rival street railroad companies have had enough of the one cent fare business and have resumed the nickel.

Palestine, Tex.—The electric light plant owned by John R. Hearne has been purchased by the newly organized Palestine Electric Light Company.

Rochester, N. Y.—The Grand View Beach Railroad has been sold at foreclosure sale for $21,000. A new company will be at once organized to operate the road.

Elgin, Ill.—There is a rumor afloat here that the Mason air brake factory has been sold to an electrical supply concern that gives employment to several hundred hands.

Norwalk, O.—The Norwalk electric light plant was sold at public auction by the assignees on the 1st inst. It was knocked off to B. P. Foster, of Toledo, for $13,000.

Sharon, Pa.—The Shenango Valley Railway, running between Sharon and Sharpsville, has been sold at sheriff's sale to J. H. White, Daniel Stone and J. F. Barker of Beaver Falls.

Allegheny, Pa.—The Westinghouse Company's bid for the engines for the new Allegheny electric plant, being the lowest, its acceptance has been recommended by the committee.

Wytheville, Va.—The town council has leased the electric light plant for ten years to J. A. Mebane, Frank Owens, J. S. Ward and E. C. Burton. Arc lights are to be put in operation within sixty days.

Kingston, N. Y.—Surveys have been made for a proposed electric road between this city and Lake Katrine. The Dwyer brothers, owners of the Lake Katrine property, are the principal promoters of the enterprise.

Watertown, N. Y.—Ex-Mayor Hiram F. Inglehart has purchased a majority of the stock of the electric street railway system of this city, thus securing control of the entire road. The company will be reorganized.

London, O.—The council has passed the ordinance authorizing the issuing of $25,000 worth of bonds for the putting in of an electric light plant to be operated by the town. The matter will be voted on at the spring election.

Flushing, Mich.—Plans have been prepared for a complete electric lighting and waterworks system for this place to cost $20,000. A special election to vote on the question of bonds will probably be called for the last of March.

Pawnee City, Neb.—The council will probably purchase the electric light plant from the creditors of the Homestead Bank. The present dynamo will then be used for an incandescent system and a new one purchased for arc lights.

Atlanta, Ga.—The reports obtained by H. M. Atkinson, chairman of the electrical committee of the Exposition, indicate that the Electricity Building will be filled with exhibits and the display of electrical machinery one of the finest ever made.

Meridian, Miss.—The contract made a few weeks ago between the city of Meridian and some parties from St. Louis for the erection here of an electric plant for a railway and lights has been set aside, as the city refused to subscribe $25,000 towards the project.

Mankato, Minn.—Petitions signed by nearly all the heaviest taxpayers of the city were to be presented to the council at its last meeting asking that a proposition to vote $15,000 in bonds for a city lighting plant be submitted to the citizens at the city election in April

East Liverpool, O.—The Merchants' Electric Light Company, recently organized here with a capital of $20,000, will contest the field with the Cerenamic City Light Company. It is thought that one of the companies will eventually be compelled to succumb, the field being too limited for two.

Los Angeles, Cal.—The board of public works has recommended that the franchise for a double-track electric railway from Bonnie Brae street to the west city limits be advertised for sale. O. A. Ivers, John S. Maltman, John Kenealy, Richard Dillon and Henry T. Hazard had asked for the franchise.

Brookfield, Mass.—A new company will at once apply for a charter for an electric road extending from Spencer through East Brookfield and Brookfield to the town hall at Warren; there will also be a branch from West Brookfield to North Brookfield. The capital stock of the company is $150,000.

New Orleans, La—E. M. Hudson, an attorney representing Eastern capitalists, has submitted an ordinance to the mayor and council for their action, which provides for the purchase of franchises for an extensive system of electric street railroads in this city and suburbs, the franchises to extend fifty years.

Atlantic City, N. J.—The Industrial Improvement and Electrical Company has asked the council for permission to operate an electric light plant in this city. The company, which is largely composed of local capitalists, expect to have its plant in operation by June 1, and will make a big bid for a city contract for five years.

Toledo, O.—A mortgage has been filed in the recorder's office by the Toledo, Maumee and Perrysburg Electric Railroad Company covering the entire road in the sum of $300,000. The mortgage is given to the Metropolitan Trust Company of New York and is secured by 300 5-per cent. bonds of $1,000 due each March 1, 1920.

St. James, Minn.—The electric light plant installed for the village of St. James by the Fort Wayne Electric Corporation having been found entirely satisfactory, the city council has given the Northwestern agent of the company an acceptance of the plant. St. James now boasts of one of the best plants in the Northwest, costing about $7,500.

Denver, Col.—The Pandora Mill near Ophir, in which ores from the Smuggler-Union mines are treated, is being equipped with electrical motors and will be supplied with current from the San Miguel Consolidated plant, eight miles away. Steam has been the motive power heretofore employed in the mill, and the change is desirable for many reasons.

Norristown, Pa.—It has been suggested that a good route for a trolley road would be from Dublin to Norristown by way of Blooming Glen, Lawndale, Souderton, Franconia Square, Harleysville, Lederachville, Skippackville and then by the best route to Norristown. C. D. Hunsberger, of Souderton, is making an effort to interest local capitalists in the line.

Summit, N. J.—It is said that a number of Summit capitalists have plans under way for establishing a big electric plant in this township near East Summit. The plant is not only to supply light, but will also furnish power for a proposed trolley road to run through Summit and connect with the trolley lines that will run from South Orange to Millburn.

Little Rock, Ark.—The Federal Court has ordered a postponement of the sale of the city electric street railway property until April 18. The decree for foreclosure was given in favor of the St. Louis and Atlantic Trust Companies several weeks ago. The hearing of the case of the First National Bank against the receivers of the street railroad company was set for March 25.

Tokio, Japan.—The Tokio Electric Light Company was started in 1887, and since that date the Department of Communications has given sanction for the organization of thirty-one similar companies throughout the country. It is reported that there are eleven applications besides these, which, should they also be authorized, would bring the total to forty-three.

Attleboro, Mass.—The North Attleboro board of selectmen have granted the syndicate headed by E. R. Price an electric franchise to operate cars in the Attleboros. The syndicate will operate over the tracks of the old Attleboro, North Attleboro and Wrentham road, and will acquire possession of the Inter State as soon as possible and run the two roads under one system.

Valparaiso, Ind.—It is understood here that a stock company has been formed, composed of Chicago, Valparaiso and Hobart capitalists, to build an electric road from this point to Chicago. The cars will be constructed so that light freight can be shipped. The principal backers interested are milk shippers, whose daily business through these two counties amounts to hundreds of dollars.

Cleveland, O.—A meeting of men interested in the proposed Cleveland and Lorain electric road was held here a few days ago to arrange for the incorporation of the company. Two routes for the road are under consideration. One parallels the Nickel Plate Railroad, and the other is near the lake and twenty miles long, two miles longer than the former route. It is intended to carry freight as well as passengers.

Buffalo, N. Y.—The White-Crosby Company has signed the contract for the construction of the Buffalo and Niagara Falls Electric Railway. The road will be built under the personal supervision of O. T. Crosby. All the stock has been subscribed.—The Buffalo, North Main Street and Tonawanda Electric Railroad has passed into the control of the General Electric Company, which had a mortgage on it. This company will operate the road in future.

Youngstown, O.—The township officials have decided to submit to a vote by the electors in April the question of issuing $20,000 township bonds to construct an electric railroad from this city to Canfield, ten miles south of the city.—New York capitalists have purchased a controlling interest in the Park and Falls Electric Railroad and will push it to completion at once. The road will extend to a summer resort five miles south of Youngstown.

San Francisco.—The Market Street Railway Company intends to have two electric roads in operation from First avenue to the ocean in a few months. In California street the tracks of the steam road will be taken up and a new standard-gauge electric roadbed put down. The road will run on the route of the Cliff House steam line and will be in operation within a few months. Both of the new roads will parallel the road now being built by the Sutro Railway on Clement street.

Appleton, Wis.—A rate war in electric lighting has begun here between the Edison Electric Company and the Citizens' Electric Light and Power Company. The former has reduced its rates, and the latter will meet the cut. The Citizens' Company have built an excellent plant and began business about a fortnight ago with 1,500 lights on their circuit. They use the alternating current system. Their light has been favorably received and they have already ordered machinery to double the capacity of their plant.

New York.—A series of experiments will shortly be made on the Lenox avenue branch of the Metropolitan Traction Company's lines to test an underground electric railway system similar to that in operation at Budapest. If the tests are successful a revolution may be expected in the operation of the surface railroads in this city.—The electrical workers' strike still continues and is helped along by the occasional accession of other bodies of men in the building trades, who hope thus to assist in bringing the contractors to terms.

Lima, Ohio.—A scheme headed by Chicago capitalists is to build an electric road from this city to Bellefontaine, a distance of about 100 miles. The road could follow the right of way secured several years ago for the Columbus, Lima and Milwaukee Railroad. All the grading and building of culverts has been done and it would require but little repairing to make the bed ready. The road passes the Lewiston reservoir, the best hunting and fishing spot in this part of the country, which is many miles from a railroad.

Springfield, Mass.—The Palmer and Monson Street Railway Company, organized here last week, will apply for a charter at once. The company starts with a capital stock of $60,000 and proposes to build an electric railroad from Monson to Palmer, Wilbraham and Ludlow, connecting with the electric line for this city. Work on the road will be begun as soon as a charter can be secured. These directors were chosen for the new company: George M. Atkins, George E. Buck, E. L. Bodrish, Rufus Flynt, of Palmer, and George C. Flynt, E. D. Cushman and R. M. Reynolds, of Monson.

Albany, N. Y.—A bill has passed the Senate authorizing trustees of the village of Batavia to provide for expenses of electric lighting and other purposes.—A bill introduced in the Senate provides for the appointment by the Governor in each judicial district of bi-partisan boards of four electrical examiners for two years, to pass on qualifications of all persons installing electrical apparatus. No member shall be interested in the manufacture or sale of any such apparatus. The board may charge from $3 to $10 for an examination, but are not to retain over $5 a day for services, and must file a statement monthly with the Comptroller. Persons operating plants of twenty-five kilowatts or less are exempt from examination. Persons not holding certificates from examiners are liable to punishment for misdemeanor, and those employing such persons to a fine of from $25 to $250 for each offence.—Assemblyman Rockwell's bill providing for examinations of applicants for positions on street surface roads as motormen or gripmen has been favorably reported in the Assembly. The applicant must be thoroughly familiar with the machinery he is to control before he can be placed in charge of a car.—The State Railroad Commissioners have granted the Ballston Electric Railroad Company permission to operate a trolley line.

Telephone and Telegraph.

A bill introduced last week in the Illinois Senate provides that no more than 25 cents shall be charged for any telegraph message of twenty words or less.

The Southern Massachusetts Telephone Company intends, if permission is granted, to put its wires underground in New Bedford.

The Fulton Chain Telephone and Telegraph Company of Boonville, N. Y., just incorporated, was formed for the purpose of constructing and maintaining a line of telephone and telegraph wires, the general route of which will be as follows: Beginning at Boonville, the home office, and following the highway to Moose river, to McKeever, to Fulton Chain and to Old Forge; to Beaver river station, with a branch from Big Moose station to Big Moose Lake, a second branch running from Old Forge to the head of Fourth Lake, thence to Racquette Lake. The capital stock is $4,000.

There will be another hearing of the telephone rate bill before the Senate Cities Committee at Albany on the 19th inst. The bill has been amended so as to raise the rate in New York City from $78 to $125 per year, in Brooklyn from $66 to $85, and in cities from 100,000 to 500,000 population it was left at $48.

At a meeting of the board of directors of the Commercial Cable Company on the 4th inst. the old officers were all re-elected. The board declared the usual quarterly dividend of 1¾ per cent. out of net earnings, payable on April 1.

A new telephone company is at work in Salem, Mass., securing subscribers with a view to establishing an exchange there, and they promise to give the citizens a better service at a less price than the present company.

The Bell Telephone Company will have three or four competitors in Philadelphia if the companies now seeking franchises in that city obtain them. The companies already in the field are the Mutual Automatic Telephone Company, the Drawbaugh and the Central.

It is reported that the Central New York Telephone Company, a Bell corporation, is buying up the stock of the Interstate Telephone Company, organized to do business at Little Falls, St. Johnsville, Fort Plain and other villages in that section.

Citizens of Beloit, Wis., are forming a telephone company and will establish an exchange at that place. Already 100 of the leading firms and individuals have signed the subscription paper. When the list reaches 125 the work of construction will begin.

The subscribers to the stock of the new telephone company at Petersburg, Va., are very earnest in the matter and apparently determined to go ahead with their enterprise whether the Bell Company lowers its rates or not.

At Albany on the 5th inst., forty-two commercial bodies were represented at the last joint hearing on the Gerst-Parsons Telephone bill before the Senate Committee on Cities and the Assembly Committee on Gas, Water and Electricity. The New York Board of Trade and the Telephone Subscribers' Association were represented by Frank S. Gardner, secretary; Simon Sterne, Silas M. Giddings, C. C. Shayne, William McCarroll, ex-Judge H. D. Cary, W. D. Stewart and E. S. A. De Lima. Gen. B. F. Tracy, counsel, and Charles F. Ontler, president, represented the Telephone Company.

United States Consular Clerk Martin, at Southampton, England, in a report to the State Department at Washington, gives some particulars of interest relative to the telegraph in England. He shows that all of the companies' lines were acquired by the Government in 1870 for $55,000,-

000 and that in the year succeeding the Government built 15,000 miles of wire to connect the various systems. As an illustration of the results of this policy the report shows that while in 1870 the total number of telegrams handled weekly by all offices was estimated at from 128,000 to 215,000, in 1893 the total exceeded 1,100,000 and the number sent annually exceeded 70,000,000. In 1869 the English press service was 22,000,000 words. It now amounts to 600,000,000 words; thirty-six times more than formerly. The rate is twelve cents for twelve words, paid in stamps. It is not possible to calculate the cost to the Treasury of the telegraph service because of its combination with the postal service; but the English Government does not consider it as a means of revenue, but rather as a means of helping trade and informing the public.

Boston Notes.

As was the case all over the United States, when the decision of the Supreme Court in the Bate Refrigerator case was received in Boston and neighboring cities there was quite a flurry all through electrical circles. The lamp manufacturing firms were especially jubilant, as the entire field was at last opened to them without restriction or limitation. There being no longer either let or hindrance, several of the more enterprising ones entered the field instanter and began cultivating it in good shape. Already there is promise of an abundant harvest.

To meet the certain increased demand for filament silk, now that the incandescent lamp field is open to all, the Boston Braid Company, which hitherto have manufactured and supplied nearly the entire demand for braided silk for filaments, have recently largely increased their manufacturing facilities to enable them to handle orders with promptness.

The annual report of the Massachusetts Gas and Electric Commissioners shows that during 1894 there were no less than nine towns that availed themselves of the Municipal Lighting Act of 1891, and have either purchased existing or established new lighting plants or are preparing to do so. Some of those now in operation are showing substantial results in the way of economic lighting of streets, stores and houses. Other towns are looking into the matter very seriously.

Packard Lamps.

The New York and Ohio Company of Warren, Ohio, state that they have since the Bate decision given up all experimental and non-infringing foolishness and are now making the straight old Packard lamp with platinum leading-in wires. They have introduced a neat little device in the shape of a "date label." This is a small label pasted on each lamp on which is printed, besides the usual candle power and voltage markings, three spaces headed respectively Fin. ——, Up ——, B. O. ——. In the first of these spaces is marked the date on which the lamp was finished at the factory, and the others are designed for the consumer to mark the date on the lamp when it is put up an the date when it is burned out. The company cla that with their new lamp there is no smashing poin as the lamps give a good light up to the moment they rn out, not falling off in candle power and efficiency as ha heretofore been the case with all incandescent lamps. The use of the date label is certainly an evidence of good faith on the part of the maker and will doubtless prove a convenience to the user.

The Mather Electric Company.

The Mather Electric Company of Manchester Conn., report the sale through their well-known Western contractor, Mr. J. Holt Gates, of Chicago, of two 55 K. W. new type direct connected generators for Fort Dearborn Building, Chicago, these generators to be used in connection with Ball & Wood engines; also the sale of two 50 K. W. direct connected generators to be used with McIntosh & Seymour engines for the Lauderdale Building, Providence, R. I.; also, one 85 K. W. 220 volt generator to the Walter Ferris Coal Company, Salem, Ohio, and two 80 K. W. new type multipolar generators in the station of the Catasauqua Electric Light and Power Company, Catasauqua, Penn. These two generators are of the Mather Company's latest type, their speed not exceeding 300 revolutions per minute.

The Partridge Carbon Company.

The Partridge Carbon Company of Sandusky continues to bask in the sunshine of success undisturbed by the fierce competition in the sale of Arc Lighting Carbons. The reason is that they devote their attention to the manufacture of high grade Motor Brushes and Specialties, and that a customer once gained for them is rarely lost. They send out a pithy folder which is worth sending for.

Notice of Removal.

It is announced that on and after March 15, 1895, the general offices of the Interior Conduit and Insulation Company will be located at the works, 527-531 West 34th street, New York City.

Wm. B. Vansize.

The offices of Mr. W B. Vansize have been removed to the Postal Building, 253 Broadway, New York, where he will be pleased to see his customers and friends.

The Hornberger Electric Company.

Mr. John C. Boss, who has been connected with the above company for about two years, has purchased the entire capital stock of the company.

INCORPORATIONS.

The Milan, Birmingham and Elyria Electric Railway Company, Birmingham, Ohio—to construct and operate an electric railway; furnishing light, heat and power. Capital stock, $100,000. Promoters: Geo. W. Clary, C. P. Baker, H. P. Starr, H. D. Olds, W. L. Fay, F. Burk, E. H. Andress.

The Ontario Electric Company, Ontario, Cal.—to produce and deal in general electric heat and power; operate water, and deal in water rights and lands. Capital stock, $100,000. Promoters: John Jenkins, Chicago, Ill.: David Elcoat, Godfrey Stamm, of Ontario, Cal.

The Galesburg Telephone Company at Galesburg. Ill.—to operate a telephone plant. Capital stock, $50,000. Incorporators: O. F. Price, Robert Chappell and H. S. Gunnell.

The Dirigo Telegraph and Telephone Company, Augusta, Me.—to operate in Kennebec and Somerset Counties. Capital stock, $50,000. President, Hon. P. O. Vickery; treasurer, J. R. Gould; general manager, C. H. O'Brien. Directors: P. O. Vickery, G E. Macomber, J. F. Hill, J. M. Haynes, G. N. Lawrence, L. C. Cornish and M. S. Campbell.

The Phœnix Telephone and Manufacturing Company, Chicago, Ill.—to manufacture and sell telephone and other electrical goods and appliances, etc. Capital stock, $100,000. Promoters: Le R. Brown, E.E. Yaxley, J. H. Riley.

The Palestine Electric Light Company of Palestine, Tex.—to furnish electric light and power to the city of Palestine. Capital stock, $20,000. Promoters: John R. Hearns, A. S. Fox, W. C. Gorman, Palestine.

The Cleveland Gas and Electric Fixture Company (incorporated in W. Va.), Cleveland, Ohio—to manufacture, buy and sell gas and electric fixtures, copper and brass goods, etc. Capital stock, $100,000. Promoters: Burton C. Tremaine, Bernard Schatzinger, Louis Paplousky, Cleveland.

The Citizens' Electric Light and Power Company, Newark, Ohio—to manufacture and furnish light and power. Capital stock, $80,000. Promoters: Wm. C. Taafel, Wm. D. Fulton, Frank C. Warden, Frank Owens, Wm. E. Miller.

The Ansonia Electrical Company, Ansonia, Conn.—to manufacture, buy, sell and deal in any and all kinds of articles, machines and supplies used in whole or part for electrical purposes, etc. Capital stock, $56,000. Promoters: Franklin Farrell, Franklin B. Platt, Thos. Wallace. Jr., Ansonia.

The American Coal Company, Seattle, Wash.—to mine and deal in minerals and fuel; operate steamboats, vessels, waterworks, railway, telegraph, telephone and electric plants. Capital stock, $300,000. Promoters: Fred'k Nolte, P. O. Skoyan, Alfred Meyers, W. A. Burleigh, Jr., Geo. E. Wright.

The Allentown and Reading Electric Street Railway Company, Philadelphia, Pa.—to build an electric street railway. Capital stock, $108,000. Promoters: Victor D. Barner, Allentown, Pa.; W. H. Kennedy, Philadelphia; P. J. Moore, Philadelphia.

The People's Telephone Manufacturing Company, at Chicago—to manufacture telephones. Capital stock, $100,000. Incorporators: John E. Dalrymple, Joseph E. Michard and B. Schottler.

The Fulton Chain Telephone and Telegraph Company, Boonville, N. Y. Capital stock, $4,000. Directors: Dwight B. Sperry, of Old Forge; James Higby and Francenna A. Higby, of Big Moose; Dennis Cannon of Chase's Lake; Daisy L. Glenn, of Pettles Corners, and Clarence R. Sperry, of Boonville.

The Cushman United Telephone Company, Chicago—to build telephone and telegraph apparatus. Capital stock, $20,000,000. Incorporators; I. M. Cushman, O. O. Leabhart and Joseph Barton. Directors: S. D. Cushman, W. C. Dean, James Falley, L. H. Chatterton, Lewis H. Falley, William Falley and John E. Crawford. The company will confine its business for the present to small cities and country towns.

The charter of the Knoxville Water and Electric Power Company has been filed in the office of the Secretary of State. The incorporators are John Bane, S. A. Bailey, John Smithson, John J. Pogue and Noble Smithson, of Knoxville, Tenn.

The Oxley & Enos Manufacturing Company of New York City—to manufacture, import and sell lamps and gas and electric light fixtures, etc. Capital stock, $1,500. Directors: Edward A. Stevenson, of Brooklyn; Franklyn Paddock and Albert E. Seibert, of New York City.

The Galesburg Telephone Company, Galesburg, Ill.—to operate a telephone plant. Capital stock, $50,000. Incorporators: G. F. Price, Robert Chappell and E. S. Gunnell.

The New York and Brooklyn Tunnel Company, New York City—to build an underground railroad to be operated by electricity or other motive power, from a convenient point in New York between East Sixteenth and Whitehall street under the bed of the East River to a point in Brooklyn between North Eighth street and Atlantic avenue, a distance of two miles. Capital stock, $1,000,000. Directors: Thomas A. Patterson, Jr., Charles J. Schlegel, Walter J. Alms, John C. Bucken, Charles Kuehnmundt: John V. Bouvier, Jr., Frederick P. Delafield, Frank H. Knight and Samuel S. Slater, of New York City.

ELECTRICAL PATENT RECORD.

LETTERS PATENT ISSUED MARCH 5, 1895.

ELECTRIC RAILROADS AND APPLIANCES.

535,214. Contact Device for Conduit Electric Railways. Frank E. Lodetti, Rondout, N. Y. Filed May 4, 1894.

535,294. Closed Conduit for Electric Railways. Patrick Murphy, Chicago, Ill. Filed Jan. 9, 1894.

535,297. Sectional-Conductor System for Electric Railways. Alfred Rosenholz, San Francisco, Cal., assignor of one-half to Samuel J. Clarke and Harvey S. Brown, same place. Filed Oct. 11, 1894.

535,308. Motor-Truck. Elmer A. Sperry, Cleveland, Ohio. Filed June 5, 1893.

535,324. Electric-Railway Conduit. William T. Dulany, Jr., New York, assignor of one half to Oscar F. Shaw, Brooklyn, N. Y. Filed Dec. 14, 1894.

ELECTRIC LIGHTS AND APPLIANCES.

535,051. Electric-Arc Lamp. Harry P. Davis, Pittsburg, Pa. Filed Oct. 23, 1893.

535,052. Electric-Arc Lamp. Harry P. Davis, Pittsburg, Pa., assignor to the Westinghouse Electric and Manufacturing Company, same place. Filed May 3, 1894.

535,069. Light-Fixture or Analogus Article. William McElroy and George W. Bayley, Brooklyn, assignors of one-third to Fred White, New York, N. Y. Filed May 9, 1891.

535,199. Incandescent Electric Lamp. Frank L. Fowler, Philadelphia, Pa. Filed July 30, 1894.

535,336. Electric-Lamp Support and Cut-Out. Lafayette Johnson, New Albany, Ind., assignor of one-half to John H. Stotsenburg, same place. Filed April 5, 1894.

DYNAMO ELECTRIC MACHINERY.

535,010. Transformer. Fred S. Hunting, Fort Wayne, Ind. Filed Feb. 25, 1892.

535,104. Armature-Winding Machine. Harry E. Heath, Windsor, Conn., assignor to the Eddy Electric Manufacturing Company, same place. Filed May 15, 1894.

535,105. Apparatus for Winding Armature-Coils. Harry E. Heath, Windsor, Conn., assignor to the Eddy Electric Manufacturing Company, same place. Filed May 15, 1894.

535,106. Method of Forming Armature-Coils. Harry E. Heath, Windsor, Conn., assignor to the Eddy Electric Manufacturing Company, same place. Filed May 15, 1894.

535,158. Method of and Apparatus for Regulating Electric Circuits. Julien M. Bradford, Portland, Me. Filed Jan. 9, 1894.

535,304. Mounting for Electric Motors. Elmer A. Sperry, Cleveland, Ohio, assignor to the Sperry Electric Railway Company of Ohio. Filed April 13, 1894.

TELEPHONE AND TELEGRAPH APPARATUS.

535,042. Telephone Apparatus. Otto L. Wullweber, Chicago, Ill. Filed Jan. 7, 1893.

535,247. Battery Telephone-Transmitter. William W. Jacques, Newton, assignor to the American Bell Telephone Company, Boston, Mass. Filed June 22, 1894.

535,284. Telephone-Transmitter. John Goodman and Henry M. Goodman, Louisville, Ky. Filed Sept. 19, 1894.

535,289. Telephony. William W. Jacques, Newton, assignor to the American Bell Telephone Company, Boston, Mass. Filed May 26, 1892.

535,299. Combined Telegraph and Telephone System. Christopher A. Shea, Boston, Mass. Filed Jan 3, 1893.

BATTERIES.

535,090. Electric Battery. Horatio J. Brewer, New York, N. Y. Filed May 2, 1892.

MISCELLANEOUS

535,027. Rheostat. Alton J. Shaw, Muskegon, Mich., assignor to Mary H. Shaw, same place. Filed Dec. 1, 1894.

535,060. Demagnetizing Apparatus. Charles Houlgrave, Buffalo, N. Y. Filed Jan. 22, 1894.

535,077. Circuit-Interrupter for Alternating Electric Currents. Henry N. Potter, Allegheny, assignor to the Westinghouse Electric and Manufacturing Company, Pittsburg, Pa. Filed Feb. 28, 1894.

535,084. Insulating-Conduit for Electric Conductors. Lewis B. Stillwell and Charles F. Scott, Pittsburg, Pa., assignors to the Westinghouse Electric and Manufacturing Company, same place. Filed Oct. 25, 1894.

535,080. Lightning-Arrester. Alexander Wurts, Pittsburg, Pa., assignor to the Westinghouse Electric and Manufacturing Company, same place. Filed Feb. 28 1894.

535,100. Burglar-Alarm for Glass-Doors. James B. Gill, San Francisco, Cal. Filed Feb. 27, 1893.

535,173. Drying Electric Cables. Charles H. Rudd, Chicago, Ill., assignor to the Western Electric Company, same place. Filed April 18, 1892.

535,267. Electrolytic Conduit for Beer or Other Liquids. Louis Wagner and John Marr, Baltimore, Md. Filed Nov. 12, 1894.

535,321. Electric Heater or Rheostat. James H Delany, New York, assignor to Ezra T. Gilliland, trustee, Pelham Manor, N. Y. Filed Nov. 23, 1894.

ELECTRICITY.

VOL. VIII. NEW YORK, MARCH 20, 1895. No. 10

ELECTRICITY

Published every Wednesday by the

ELECTRICITY NEWSPAPER CO.

B. E. GREENE, PRES'T. L. J. MONTGOMERY, SEC'Y.

PUBLICATION OFFICE:

6 Park Place - New York

EDITORS: NELSON W. PERRY.
BURTON E. GREENE.
R. H. WILLOUGHBY.

SUBSCRIPTION RATES:

UNITED STATES, - - - - - $2.50
IN CLUBS OF FIVE OR MORE, - - - - - $2.00
FOREIGN COUNTRIES, - - - - - - $4.50
SINGLE COPIES, - - - - - - - 10 CENTS

ADVERTISING RATES:

As ELECTRICITY reaches all classes interested in electrical work, its value as an advertising medium can be readily appreciated. Rates will be sent on application.

Changes for advertisements should reach the office not later than the Saturday preceding the date of publication.

ENTERED AT THE N. Y. POST OFFICE AS MAIL MATTER OF THE SECOND-CLASS.

TRADE SUPPLIED BY
THE AMERICAN NEWS COMPANY,
THE WESTERN NEWS COMPANY,
And their Agencies in all Principal Cities.

EDITORIAL NOTES.

General Electric's "Profits"? The fiscal year of the G. E. Company ended January 31. Every fact and figure needed for the annual report was in hand before March 1.

If the company's management is honorable, and the condition of the property has improved, why are the main results not published to reassure the stockholder who has seen every dollar of his investment shrink to 30 cents?

If there is anything in the actual condition of affairs to encourage any one, why is it not made known?

In regard to the claims of large business being made for the General Electric Company, either with or without official sanction, investors and others will do well to bear in mind the changed conditions as to prices and possible *profits* between 1892 and 1895. Even if it were true, as stated, that the company is doing $12,000,000 gross per year, would there be any profit?

The following comparative statement of prices will, we think, answer this question more conclusively than columns of arguments. The table is made up from authoritative sources and is correct:

COMPARATIVE STATEMENT OF G. E. PRICES ON APPARATUS, 1892-1895.

	1892.	1895.
Railway motors (two 25 H. P.), per car equipment	$2,500	$650—$850
Series arc machines, with lamps, per light	$65—$75	$30—$35
Series arc lamps, S. C.	$40—$45	$15
Double carbon lamps	$50—$60	$20—$25
Incandescent arc lamps	$25	$10—$15
Incandescent lamps (16 C. P.)	44 cents.	20c.—25c.
Bipolar belted machines (lighting or railway), per K. W.	$33	$10—$15
Multipolar direct connected lighting machines	not made.	$30—$35
Large railway generators, direct connected, per K. W.	not made.	$20 to $30
Alternating apparatus, per light.		$3—$1.50
Transformers		$2—$1.00

Railway equipment work is over one-half of the company's business, and on this class of work the prices average less than *one-third* of those of 1892.

On minor articles of manufacture, switches, sockets, cut-outs, etc., the present prices are about 40 per cent. of what they were three years ago.

Will the annual report include this information?

We have no hesitation in stating our opinion that the present position of the G. E. managers is that of stockjobbers, as it has mainly been from the first.

It is on record that Mr. C. A. Coffin was one of the largest operators on the short side of the market while G. E. was tumbling from 100 to 50 and before the public knew that dividends must be stopped.

Our view at present is that insiders, knowing the disastrous effects of the publication of the annual report upon the speculative market, are operating with a view to making as many turns in the stock market as possible before the final slump which must carry G. E. somewhere near the price where it will slumber and cease to be a factor in the market—about $10 per share.

* * *

No Consolidation, and Why? The consolidation scheme which was mentioned in ELECTRICITY last week has ended, according to our best information, in giving no comfort to investors in G. E. stock.

For more than two years the manipulators of this company's finances have endeavored to bring about a deal of some kind whereby G. E. and Westinghouse interests might work in harmony.

The ultimatum of the Westinghouse interests has been from the first, when the situation was carefully studied, that no consolidation, as such, was possible, and that no consideration could be given to the project of a sale of a controlling interest in G. E. to the Westinghouse interests until the G. E. Company had gone through a receivership and become freed from its endless entanglements in various towns and cities with local lighting companies and subsidiary manufacturing companies.

This ultimatum stands to-day.

The latest scheme was carefully planned, and was given thorough consideration by several gentlemen who are known as Standard Oil men. After several consultations, it was apparent that the negotiators could not deliver the goods, and the conclusions reached by the capitalists and expressed to the intermediaries were substantially as follows:

It had been represented to us that a proper combination of capital and business ideas could control the electrical manufacturing business, that prices might be advanced somewhat, the product improved and a fair return made sure upon the necessary investment. Investigation has convinced us that this is not the case, and that no combination, of which we can be the head, can possibly control the business.

It looks to ELECTRICITY very much as though the Westinghouse interests were sound in their fixed resolution not to combine on any terms with a company which is already beaten.

The works at Brinton are now in full blast, everything having been transferred from Pittsburg. If there is anything in past experience, with the most modern and thoroughly equipped electrical shops in the world located close to the main base of supplies, with advantageous freight rates, moderate priced labor, low fixed charges, etc., etc., the Westinghouse Company now have the General Electric people at their mercy; and this condition of affairs will show results before many weeks.

The fittest will survive, and ELECTRICITY goes on record in the prophecy that the fifty-million-dollar G. E. enterprise will yet bow at the feet of the ten-million-dollar Pittsburg enterprise—receivership and all.

* * *

The Niagara-Buffalo Transmission. In our issue for March 6th we discussed editorially and at some length the propositions submitted by the Niagara Falls Power Company to the city of Buffalo. These propositions were three in number, and briefly as follows: (1) To sell 10,000 H. P. undeveloped on the lands of the company at $10 per H. P. per annum—the city of Buffalo to make its own wheelpits, side tunnels, put in its own wheels, dynamos, transformers, erect and operate the same and transmit the resulting current to Buffalo, there to find its own market and distribute to its customers. (2) To sell 10,000 H. P. developed on the turbine shaft at $18 per H. P. per annum, and (3) to sell 10,000 H. P. electrical alternating current at 2,000 volts at the dynamo terminals at $18 per H. P., the city of Buffalo to furnish step-up and step-down transformers and line, etc. Our conclusions were that none of these propositions could be considered for a moment from the fact that the questions of transmission and distribution were still unsolved as far as the most economical method was concerned, and that the necessarily heavy fixed charges would in all probability make the power when delivered too costly to enable it to compete successfully with locally produced power by means of steam engines using coal at $1.80 per ton—the figures given by Mr. Perkins as the price of coal at Buffalo.

The light in which we presented the case was a revelation to many who had not looked into the subject further than to accept the rosy statements of enthusiasts on the subject, and our remarks have caused no end of comment among those who had expected better things. Among those who have noticed our editorial is the Buffalo *News* of the 11th inst., which, after quoting us somewhat at length, says:

> "If all this is true it will probably pay the manufacturers of Buffalo to buy coal and turn it into electrical power, as the Buffalo Railway Company is doing, at a reduction of one-third of its cost of hauling cars, rather than buy the Falls power at all. But we believe the figures of ELECTRICITY will bear revision.
>
> "Has it occurred to that authority that the Buffalo Railway Company has already solved the problems of both transmission and distribution? That company is sending power over 125 miles of wire in the City of Buffalo every day and every hour, and distributing it as needed to its different lines—and making money thereby. And every electric railway company in the country is doing the same thing. The 'appalling' figures sound very much like scare talk."

Our contemporary has fallen into a not uncommon popular error, viz., that the length of a city railroad line is the distance of transmission. We have no reason to doubt that the Buffalo Railway Company is distributing current over 125 miles of wire. In some cities, such as Brooklyn and Boston, the mileage of single companies greatly exceeds this, yet probably in no case does the actual transmission exceed six or seven miles. Nor has the question of efficient transmission yet been solved by electric street railways anywhere, for it is doubtful if in the most skilfully constructed and operated road in the country the efficiency between engine and car axle will average 40 per cent., yet with even these large losses greater profits can be made than with horses. The illustration brought forward by our contemporary to contravene our conclusions is therefore an unfortunate one.

It is impossible with the data at hand to go into a detailed estimate of what power will cost after transmission to Buffalo, nor does it seem desirable to attempt such an estimate. All we can do is to deal with generalities, and dealing with generalities the conclusions are as stated. We may take the subject up from another standpoint, however, and this may be better understood by the layman, perhaps, than the other view.

It will be clear that if Buffalo buys, say 10,000 H. P., at Niagara Falls at the rate of $10 per H. P., it is like buying a sixty ride commutation ticket at ten cents per ride, or $6. You are entitled to ride sixty times on that ticket, and if you avail yourself of the privilege your rides will cost you ten cents each. If, however, you ride but thirty times your fare stands you at twenty cents, and if you ride but once it costs you $6.

The proposition of the Niagara Power Company is to sell a H. P. at the Falls for $10. If the city of Buffalo or any one else accepts this proposition it must pay $10 for the H. P. whether it uses it or not. It has the *privilege* of using it for 8,760 hours in the year. What can it afford to sell this power for at Buffalo? Let us take the maximum efficiencies that actual practice under favorable conditions will give, and see how much of this horse power we have to sell after transmission and distribution. We think no one will claim a *better* chain of efficiencies in actual practice than the following:

Efficiency of turbines, 80 per cent; turbine shaft, 95 per cent.; electrical efficiency of dynamo, 90 per cent.; combined efficiency of step-up and step-down transformers and electrical transmission to Buffalo, 75 per cent.; efficiency of transformation from alternating current to direct current, 90 per cent. This will leave but 46.17 per cent. of the power we have bought to sell, and it has cost us $10, or at the rate of $21.66 per H.P. if used continuously. In electric lighting stations the average consumption rarely is as high as 40 per cent. of the maximum, but let us assume that in Buffalo the average demand will equal 60 per cent. of the maximum. The maximum which we have to deliver is but 0.4617 H. P., but the average demand upon which we could rely would be but 0.277. This has cost us $10 at Niagara. Its cost at Buffalo is therefore at the rate of $36.10. If we allow an efficiency of 90 per cent. for distribution, it will cost $40.11 per H. P. But we have charged nothing for interest and depreciation on wheelpits, side canals, wheels, transformers, dynamos, or line: nothing for labor, attendance and administration; nothing for expert advice, cost of experimenting, or interest on investment during period of installation; nothing for right of way, insurance or buildings, and nothing for the interest on the investment for apparatus, etc., which the customer must make before the power delivered at his door can be available, and which will be a factor with him in deciding whether he will become a customer or not. We will not attempt to figure out what these additional charges should be but will leave that for those more directly interested to determine each for himself, but we cannot for the life of us make a favorable showing for these propositions even under assumed almost ideal conditions such as can never be realized in practice.

* * *

One of Our Critics. One P. H. Johnston owns the *Electrical World*. He is therefore the editor or anything else he chooses to call himself. To be sure, he employs men who are thoroughly capable electricians to do most of the technical work for him, and so long as he leaves this entirely in their hands it is exceedingly well done and a credit to electrical journalism. But sometimes he likes to soar above the atmosphere of Baxter street and try to create a flurry in technical circles. He usually succeeds. In one instance he undertook to teach us mathematics and enunciated the astounding proposition "that if our units of linear measure were based on π then the ratio of the circumference (of a circle?) to its diameter would be unity." One of the young men in the office evidently "called him down," for in the next issue he attributed the statement and the arguments based on it to a "*slip of the pen.*"

In the issue for March 16 Mr. P. H. Johnston again lets himself loose as follows:

ELECTRICAL MISINFORMATION.

Referring to the electrical transmission of power from Niagara to Buffalo, an electrical contemporary says editorially: "We think it is safe to say that this transformation of the water power into electricity will not be with an efficiency of more than 85 per cent.; that the *transmission efficiency* will not exceed 75 per cent.; that the trans-

> *formation* at Buffalo will not average 75 per cent., and that the *distribution* in Buffalo will not be at greater efficiency than 80 per cent." In the same article it is stated that the transmission loss in the 110-mile Frankfort-Lauffen experiment was "but 25 per cent.," whereas the entire losses—from the generator, step-up transformer, line, step-down transformer and final distribution—were, in fact, between 24.7 and 31.5 per cent., the power transmitted varying from 78.2 to 197.4 H. P.

Does Mr. P. H. Johnston think that in practice the efficiency of transformation from water power into electricity will average better than 85 per cent? If he does, can he point to a single installation where such a high efficiency has ever been maintained? Does Mr. P. H. Johnston think that it will pay to transmit from Niagara Falls to Buffalo—say twenty miles—with greater efficiency than 75 per cent? If he does, can he mention a single instance on record where such an efficiency, including the losses of step-up transformers, has been *maintained* over a distance of twenty miles? Does Mr. P. H. Johnston think an efficiency of 75 per cent. in step down transformers, and conversion of a portion of the energy into direct currents too low? If he does, can he point to a single case where such an efficiency can be maintained the year round under the fluctuating loads that are likely to be met? It might be said that the transformers can be cut out as the load decreases so as to keep the remaining ones always working at nearly their best load, but if, as in three of the propositions made by the Niagara Power Company, the city of Buffalo is to pay for a maximum amount of power at Buffalo, the efficiency of a transformer that is cut out of circuit because of decrease of load is, so far as the amount of power left for distribution is concerned, zero. Does Mr. P. H. Johnston think that 80 per cent. efficiency in distribution all the year round is too low? Well.

As regards the information volunteered in regard to the efficiency, etc., at the Lauffen-Frankfort experiment, we think Mr. P. H. Johnston would have done well if he had posted himself as to what was actually done there before trying to correct others. As a matter of fact, there was practically *no* distribution attempted there unless supplying a bank of lights directly from the transformer terminals may be regarded as distribution. And further, the high efficiency announced was obtained, not under conditions of variable load, or under commercial conditions, but only from dynamo shaft to point of distribution (?) at *full load*. We make this latter statement on the authority of Dr. Walter Lobach, who was in charge of that portion of the work on the Frankfort-Lauffen plant done by the Allgemeine Electricitats Gesellschaft.

Perhaps, however, all this was a slip of the pen—and if so, we will forgive it.

* * *

I. JOHN BEGGS is again in trouble. Judge Wilson, at Cincinnati, has decided that the contract of the Cincinnati Edison Company for city lighting is void, the city not having the legal power to make a contract at the time it was signed.

Taking into consideration the fact that the same week this decision was handed down a new lighting station was started in Harrisburg as a competitor of Mr. Beggs's old station there, it looks as though John had enough to do to attend to his own business without trying to run the N. E. L. A., where his services are not required.

Under the Searchlight.

Views and Opinions on Timely Topics.

A "Casual Statement."

G. E.'s Enormous Force.

(From the "Boston Advertiser," March 5.)

> The G. E. Company's pay roll Saturday had 40.000 names upon it, a larger number than at any time since the bottom fell out of the electric business in 1893.

Averaging $2 per diem this army would create a pay-roll of $480,000 per week, or $24,000,000 per annum—about three times as much as the gross business of the concern.

Before the above statement can be accepted as fact, however, it will have to be resolved upon by the full Board.

* * *

A DISCRIMINATING VIEW.

High Praise, but None Too High.

(From the New York Sun.)

> The destruction of Nikola Tesla's workshop, with its wonderful contents, is something more than a private calamity. It is a misfortune to the whole world. It is not in any degree an exaggeration to say that the men living at this time who are more important to the human race than this young gentleman can be counted on the fingers of one hand; perhaps on the thumb of one hand.

We believe that nothing is really lost to the world by this fire, and that an unfortunate delay is the worst that has happened. This is serious enough, and the entire world joins ELECTRICITY in the hope that this delay may be brief.

* * *

AND THERE ARE OTHERS.

A receiver has been appointed for the Winona, Minn., Street Railway Company.

The G. E. Company holds $20,000 of the bonds of this company, and is liable, through Northwest G. E., for $100,000 more, sold under guarantee to the United Electric Securities Company.

It is thus the $12,000,000 deficit is being made up.

* * *

Too Late for this Year's Report.

> The Los Angeles Consolidated Electric Railway Company has been taken possession of by the bondholders on account of default in payment of the half year interest on the $3,000,000 bond issue due last September.

The G. E. Company holds $41,440 of these worthless bonds—gone to join Pueblo and Little Rock.

* * *

Will New York be the Next?

> General Manager Hanford says the Harrison Telephone Company will have an exchange in Chicago, and service will cost the public about $60 per year; present Bell charge $125.

* * *

THE strong efforts being made by the National Carbon Company of Cleveland to create a monopoly in that line are attracting considerable attention. So far as their efforts may be in the line of improving product and lowering prices, no one should find any fault. The fact is, however, that improvement comes only with competition, and some of the independent companies have already outstripped the large concerns in producing a cored carbon of unquestionable merit. In an early issue we shall devote more space to this subject, which has two sides, and is, we believe, worthy of discussion. From the point of view of the consumer, it would seem certain that the independent companies should be well supported. Carbons are an important element of central station supply.

They can now be bought *cheap* and *good*. What would be the situation if the smaller concerns should be driven out?

* * *

A CORRESPONDENT calls our attention to what he considers our injustice in not mentioning, in last week's editorial on the Lamp Situation, the fact that the Beacon Lamp Company of Boston was an important factor in the fight which prevented the G. E. interests from obtaining a monopoly of the lamp business between Judge Wallace's decision and the time of the patent's expiration. We were not, however, discussing this phase of the matter, and we mentioned the only two companies which, for legal reasons, were in position to continue making the standard type of lamp regardless of the outcome of the Bate case.

When we consider the value of courage, fighting blood and nerve in blocking the plans of the G. E. monopolists, we give full credit to the Beacon Company and to Mr. H. S. Kaliske. They made a gallant fight, and spent thousands of good money which went far to prevent the business from being bottled up.

* * *

INDUSTRY AND ECONOMY.

We wonder how many reflective men, when they contemplated the scene of gaiety in Dr. Charles Betzler's private office at Cleveland, during the meeting of the N. E. L. A., were reminded, as we were, of a story, often heard in our youth, of the Industrious Farm Hand.

He had hired out for the season at $15 per month and his board. For nine months he had toiled faithfully and had fulfilled the letter and the spirit of his contract. The first rays of morning light had found his cowhide boots brushing the dew from the pasture grass as he rounded up the cows to milk, so that the work of the day proper could begin promptly at 6 A. M. Not until it was too dark to work in the fields had he repaired to the barn to do the evening chores. Sundays he had rested by greasing the wagons, oiling the harness, salting the cattle, splitting wood for the next week, and at other light diversions.

Now the season was ended, the crops were harvested, the corn was husked, the potatoes in the cellar, the threshers had come and gone, and the faithful farm hand decided to take a week or two of rest in the city. His savings had amounted to $125, and with $6 of this he purchased a round-trip ticket. The first evening he wandered forth among the lilies of Hester street. . . . The next morning he was seated on a barrel at the depot waiting for the first train to take him home. He emptied his pockets and found his savings reduced to 18 cents. Between yawns and pangs of remorse, as he thought of the happy summer past and gone forever, he whispered in a languid way, "Oh, well; easy come, easy go."

* * *

You Hit It Right.

The *Progressive Age* in its issue for March 15 gives the whole thing away. We have been found out and must confess. Our contemporary says:

> "Some two weeks ago a thief broke into the First Presbyterian Church, Girard avenue and Hanover street, Philadelphia, and carried away a Welsbach light. Nothing else was missed from the church. It is hard to hold suspicions against one's fellowmen, but could it be that ELECTRICITY's fanatic fondness for the Welsbach has at last developed into kleptomania?"

It was not our fondness for the Welsbach light, however, that prompted us to the act, but our deep veneration for the sanctity of the edifice. We believed that so long as the Welsbach light remained there would be sufficient provocation for profanity on the part of those who had to take care of it or sit under it to warrant irreverent expletives, and we took it merely to remove this temptation. *Respice finem.*

* * *

A LEGISLATIVE investigating committee is now at work in Syracuse on matters pertaining to municipal crookedness. We wonder if ELECTRICITY will be compelled to record improper doings on the part of any of our friends.

Why, O Soul, Art Thou Sorrowful?

And Why Cast Down Within Me?

(From the New York Press.)

Nikola Tesla has lost many months of labor and research, but he still has his eulogist, Colonel Patton, late of the United States Army—Lieutenant Patton in the Army Register, but Colonel by the permission of his friends and himself. . . . But for Colonel Patton it is doubtful if Nikola Tesla would ever have been recognized by the world as the inventor of the rotating magnetic field. The inventor has suffered an irretrievable loss, a loss that cannot be measured by dollars and cents. He is one of the geniuses of this age. He stands beside Thomas A. Edison, the renowned electrician; Prof. Elihu Thomson, electrician of the Thomson-Houston Electrical Company; Charles F. Brush of the Brush Electrical Company; Gardiner C. Sims and Prof. Alexander Graham Bell.

* * *

The Flatlands Station.

Who is in Trouble?

Three Flatlands, L. I., officials have been indicted for bribery in Brooklyn—the Town Clerk, John S. Schenck; the Justice, John T. Ford; and the Tax Collector, Frederick Lemken.

In December, 1893, these officials gave the Flatlands Electric Light Company a twenty years' contract for lighting Flatlands, at $45,000 a year. Ford and the clerk, Schenck, are accused of accepting a $1,500 bribe to vote for the contract. Lemken is charged with paying them the money to influence their vote.

* * *

Twenty Per Cent. Per Watt.

Comptroller Wallace of the Canadian Government has decided that electricity comes under the head of unenumerated articles, and consequently bears a duty of 20 per cent. The question arose over a proposition to transmit power from the American side of Niagara Falls to surrounding Canadian cities.

Which means, we suppose, that the Canadians have not forgotten that they have an opportunity of their own for a large transmission plant—provided the American company proves successful.

* * *

They Don't Want the Earth—Only New England.

(From the New York Tribune.)

The New York, New Haven and Hartford Railroad has the unlimited effrontery to ask the Connecticut Legislature to refuse charters to electric railroads which may seek to compete with the Consolidated system. Meekness, humility and regard for the public welfare were always conspicuously lacking in the management of the New York, New Haven and Hartford Railroad.

* * *

Mr. E. R. Gilman is endeavoring to re-organize the Great Western Manufacturing Company, making the creditors stockholders in the new enterprise. This apt pupil of C. A. Coffin always has a new scheme, but we doubt very much if this one will work. Several charges of fraud should be settled before he makes another public appearance.

* * *

If the system of trying American patent causes were correct, conducted in accordance with the strict rules of justice, the attorney coming into court with a case like one of the recent ones brought by the Otis Elevator Company (and the G. E. Company) against the A. B. See Company would be disbarred. It is blackmail and nothing less, in our judgment.

* * *

Not the least interesting story of intrigues in the electrical business in the past three years would be the connection of the G. E with the Elevator Trust and the doings of that trust.

* * *

We commiserate Mr. A. P. Ide over the disrespectful treatment he is receiving in his own town, where the Capital Electric Company have started in business as competitors of the old lighting company, in which Mr. Ide is interested. The new concern has not bought Ide engines, and Mr. Ide has therefore recommended his employees to boycott the tradesmen and others who are stockholders in the company. We never knew before that Mr. Ide was so funny—we supposed the pull of the Eastern connection with the G. E. interests was so strong that Mr. Ide would not seriously mourn the loss of so small a sale.

* * *

It is not unfrequently that we note gems of literature in Pudd'nhead Johnston's paper—known to some as the *Electrical World*. In fact these gems occur so frequently as not to excite comment, but here is one that is certainly worthy of framing for preservation. Strange to say, it is not of Pudd'nhead's own, but must be credited to Mr. Hering. In the Digest of Current Technical Electrical Literature, in reviewing an article on efficiencies of apparatus in a central station, he says:

"With steam-generated electric energy used for heating, the waste would be 94 per cent., *the amount of coal required* would *therefore be* 94 *per cent.* [Well! well! Carl. We suppose the steam made up the other 6 per cent.!], while in an ordinary stove it is probably about 45 per cent. The amount of coal would therefore be *nine times as little*." Oh my! Carl, how could you! And to think that the literary Frenchman from County Clare—the talented editor of the only Baxter street sheet—passed this. Oh! Pudd'nhead! O'Johnston!

Some weeks ago there was a strike among the pullers-in along Baxter street and the Bowery because some of the clothing houses employed non-union pullers-in. This was at the time that Pudd'nhead Johnston started up his memorable Baxter street methods in his so-called journalism. The union strikers won in the fight, and the Irish philosopher has been in the dumps ever since.

Flushed with the cordial and hearty reception which he received at Cleveland from those who admire him personally and especially his methods, he seems determined to take it out of the hides of his employees, and the result is that it is reported that the offices of our contemporary are in a state of anarchy.

Denver, Col., Feb. 22, 1895.

To the Publisher of Electricity.

Dear Sir: We do not remember when our subscription expires, and when it does we do not want to be dropped from the list, but would request you to mail us bill for the next year.

We notice in Electricity that the news is not taken from or published in any of the other electrical papers, and therefore we are continually receiving new information, etc., from your paper.

With the other electrical papers, if you take either one you get the news of all.

This is no "blarney," it is a positive fact.

Wishing you success, we are

Yours truly,
Geo. Wm. Russell, Jr.,
President and Manager.

With a whoop and a whirl the *Electrical World*
To come out quite early does seek;
It used to come out on Wednesday night
But now it comes out next week.

Low Temperatures and the Attractive Power of Magnets.

A communication was made to the French Académie des Sciences on February 4 by M. Raoul Pictet on the "Influence of Low Temperatures on the Attractive Power of Artificial Permanent Magnets." The author stated that the experiments referred to were made with a magnet weighing 493·5 grammes, and formed of three elements in horseshoe iron. After magnetization the magnet was made to carry its charged armature for two years. It could then sustain 4,275 grammes. It was subsequently left for eleven months without armature, and then could only bear 3,226·5 grammes. The magnet was then placed in a small frigorific vessel filled with pure alcohol; it was arranged vertically with the poles or branches in the air and stayed with pieces of wood. The alcohol in which the magnet was placed was caused to touch the surface of a glass 3 millimeteres thick placed horizontally upon the branches. Two thermometers indicated the temperature of the alcohol, maintained constant by an agitator. The armature of the magnet in contact with the upper surface of the glass was fixed to the plate of a sensitive balance. It could only rise one-fifth of a millimeter, and was retained by two points closing an electric current which passed through a galvanometer. The following table gives the averages of the results obtained by four series of observations, in which the differences were always less than 1·50 grammes:

Temperature of the magnet. Degrees.	Power of magnetic attraction. Grammes.	Temperature of the magnet. Degrees.	Power of magnetic attraction. Grammes.
+ 30	57·31	— 40	66·70
+ 25	57·87	— 45	67·41
+ 20	58·48	— 50	68·45
+ 15	59·10	— 55	68·91
+ 10	59·81	— 60	69·64
+ 5	60·36	— 65	70·30
+ 0	61·04	— 70	71·19
— 5	61·80	— 75	71·98
— 10	62·42	— 80	72·70
— 15	63·42	— 85	73·41
— 20	63·93	— 90	74·18
— 25	64·60	— 95	74·95
— 30	65·35	— 100	75·80
— 35	66·09	— 105	76·64

A Long Interurban Electric Railroad.

The construction of the first interurban electric railway system of any magnitude in Western Pennsylvania is, after many delays, an assured fact. The line in question connects Greensburg to Pittsburg passing through Jeannette, the natural gas and great plate-glass center; Irwin, Manor, Penn, Stewart and other towns of the gas coal section; Walls and Carnegie, seats of extensive railroad shops; Wilmerding, the location of the Westinghouse Air Brake Works; East Pittsburg, of the Westinghouse Electric Company's new works; Braddock, the home of the great Carnegie steel plants, and many other smaller towns adjacent to Pittsburg.

The company which will construct the line is largely composed of Eastern capitalists, of whom ex Judge Saddler, of Carlisle, Pa., is the head. All the necessary rights of way have been secured and work will be commenced with the opening of spring. A mortgage for $500,000 was recorded at Greensburg a few days ago by the company in favor of the Union Trust Company of Philadelphia. Bonds will now be issued, the proceeds to be applied to the construction of the road. The first ten motors of the road will be completed within two months, and by August it is expected cars will run from Greensburg to Pittsburg, a distance of about thirty-five miles.

The Greensburg and Pittsburg Company has bought the Greensburg and Hempfield road of two miles in Greensburg for $48,000. This line was the first to be equipped with Westinghouse motors and old United States horizontal type generators. It has not been a paying investment, and the stockholders being anxious to sell, the offer of Judge Saddler was accepted without much delay. The purchasers will incorporate this line as a part of their Greensburg-Pittsburg system.

LARGE ARC DYNAMOS.*

BY CHAS. N. BLACK.

Glancing back over the last fifteen years and noting the rapid progress made in all branches of electrical engineering, it appears strange that arc dynamos have met with so few changes, more especially so when we remember that arc lighting was one of the first branches of the science reduced to practical use on a large scale. It is impossible to ascribe this to the fact that there was nothing left to be desired in the design or the efficiency of this type of machine, since it has always been notoriously weak in respect to efficiency, and has by no means kept pace with the incandescent dynamo. Within the past eighteen months, however, various manufacturers have awakened to this fact, and we have seen the results in numerous descriptions of arc dynamos appearing from time to time in the technical journals. The general tendency seems to be toward larger units and lower speeds; but, although the increase in size has, of course, increased the efficiency to some extent, we still notice the massive field magnets with their enormous amount of copper, and the small armature, which alone is enough to account for the inefficiency of these dynamos. Another noteworthy fact is that, with one exception, which perhaps I need not mention, all the new machines thus far described are of what is known as the closed coil type. This is the more remarkable when we consider that fully seventy-five per cent of the arc lights in this country are run from open coil dynamos. The open coil dynamo at the very earliest date appealed to such men as Charles F. Brush and Elihu Thomson as being especially suited for this constant current work, and by the remarkable genius of these pioneers was so perfected that to-day machines with scarcely a single alteration from the design of fifteen years ago are being sold in competition with the latest closed coil dynamos.

Fig. III

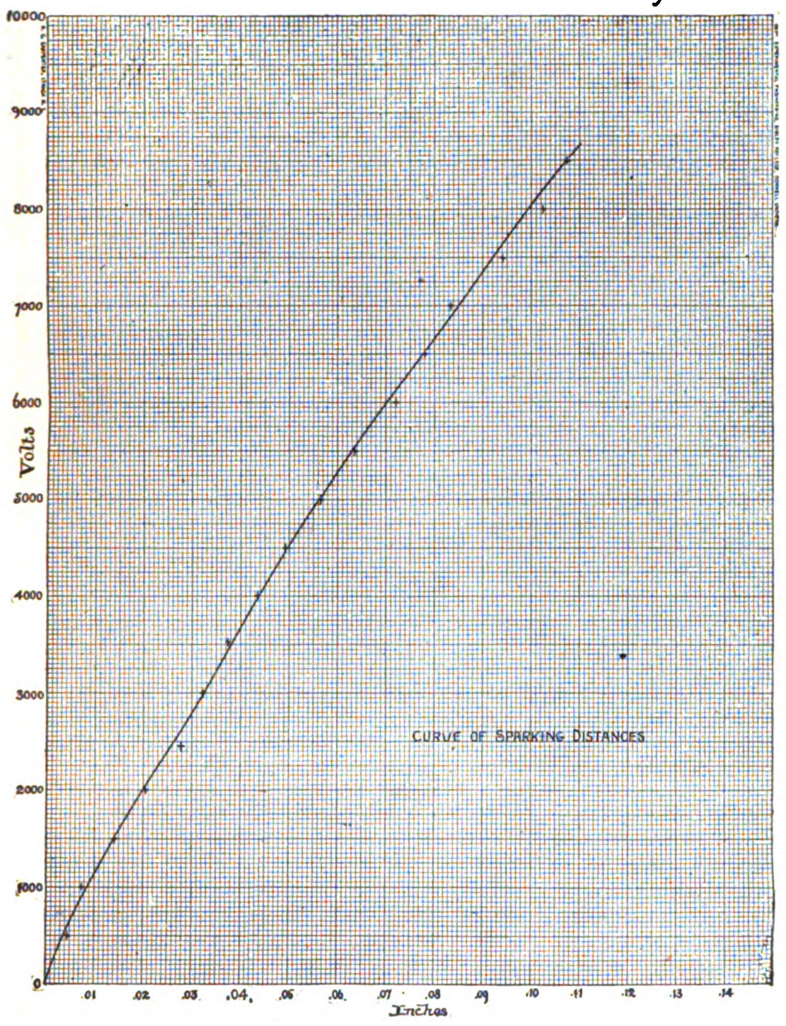

Fig. XI

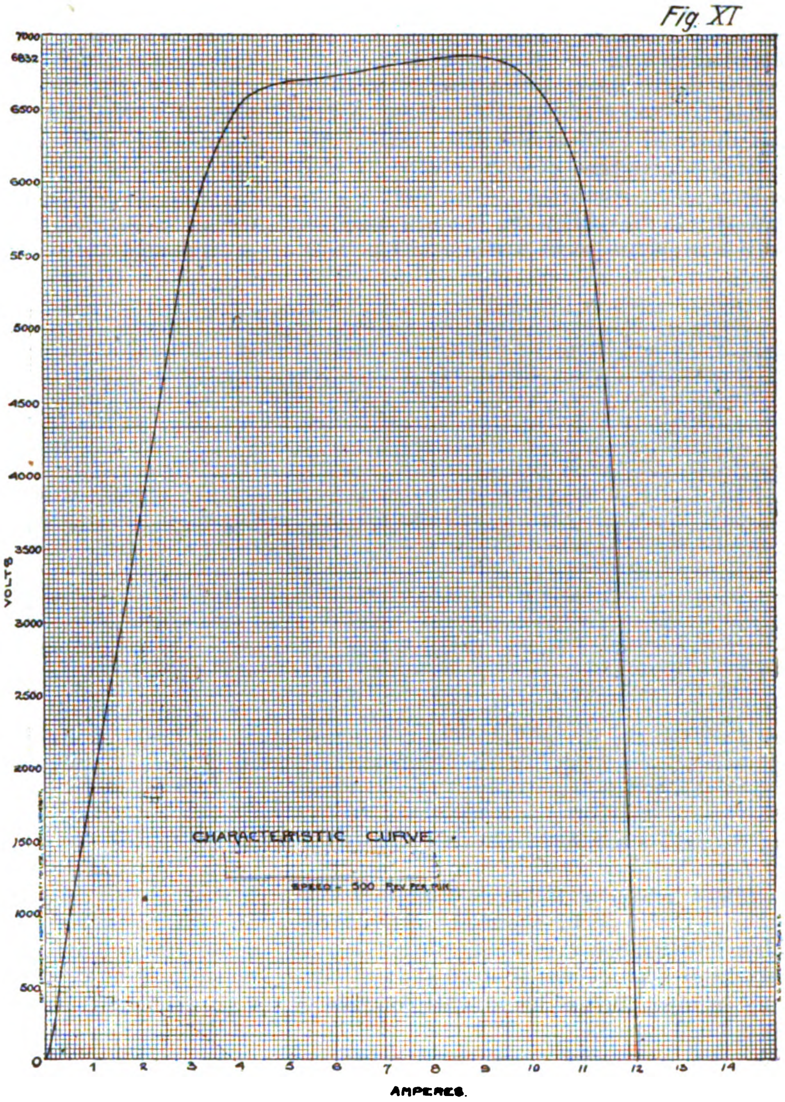

The question as to the reasons for this preference naturally suggests itself, but before answering it I will briefly describe some of the most marked points of difference between the two classes of machines. As the name implies, the open coil machine has the separate coils or sections of the windings of the armature entirely distinct one from another. In other words, they do not form a closed circuit.

It will be observed in the open coil armature that each coil or bobbin, as they are generally called, has a large number of turns, and that there are but few commutator segments, while in the closed coil armatures we have exactly the reverse, namely, few turns per coil and a large number of commutator segments. This is due to the different manner in which they commutate. In the open coil machine a large amount of self-induction in each bobbin is by no means objectionable; in fact, one might almost say that it is essential in order to obtain the best results, while in the closed coil machine the less self-induction there is in each bobbin the better the action at the commutator. The latter is true of all closed coil machines, whether for arc or incandescent lighting, as all engineers well know who have had any experience in the designing of dynamo electrical machinery.

The first statement, however, is not nearly as well understood even by those who have had considerable experience with the open coil machine. The fact that a large amount of self-induction is advantageous in an open coil machine has never, to my knowledge, been stated before, although on it depends the successful working of a machine of 2,000 volts or more. Silvanus P. Thompson in his "Dynamo Electric Machinery" gives a very clear account of the manner in which an open coil machine commutates. To one unfamiliar with this dynamo, it is always a matter of wonder that the spark does not cut away the segments. As a matter of fact, it does so to a certain extent, but the current is so small, and whatever heat there is is radiated so rapidly, that the effects in practice are almost inappreciable. At this point the self-induction of the bobbin plays an important part; were it not for this, the current in the bobbin, which is being cut out, would be reversed before the segment had reached a sufficient distance from the brush to prevent the current jumping back across the heated air space and thus causing the machine to flash.

The design and proportioning of the field magnets are the same as in the closed coil machines. It is in the commutator and commutation, then, that we find the most marked difference between the open and closed coil arc dynamos, and herein lies the great superiority of the former over the latter. Take, for example, a new open coil 125 lighter and one of the latest closed coil 100 light machines. In the one there are 24 segments in the commutator, while in the other there are 160. To go into details as to which is the easiest to insulate and keep in repair is scarcely necessary before a society of practical managers and engineers.

Some advocates of the closed coil dynamo, however, claim that such a small number of commutator segments causes a discontinuity in the current and consequently a greater strain upon the insulation of the line. This is not a new objection to the open coil dynamo, and has been answered long ago. It seems, however, to have been revived recently, and I have noticed that one builder of closed coil apparatus lays great stress upon the fact that its machine generates an absolutely steady current, and therefore puts no undue stress upon the insulation of the line.

---

*Paper read before the National Electric Light Association, February 19, 20 21, 1895.

In 1887, Mordey, in England, made the following experiments upon a Brush machine in order to determine how much fluctuation there really was. Six converters, each made to transform from 2,000 down to 100 volts, had all their primary and all their secondary coils joined in series. The current from the Brush machine was sent through all the low tension coils, and then, with a Cardew voltmeter, he attempted to measure the difference of potential at the terminals of the secondary or fine wire coil. The pointer, however, remained at zero, showing absolutely no E. M. F. He then applied the wet hands across the terminals of the whole series, but with equally negative results. An experiment which I myself made not long ago confirms fully these results. The current from a closed coil dynamo, which had 72 bars in its commutator, and which therefore gave practically a steady current, was passed through the field coils of a 125 light arc dynamo, and the fall of potential was measured with a Weston voltmeter. The machine was then run self-exciting, and the drop through the field was again taken. The currents in both cases gave identically the same readings on the voltmeter. That there is a discontinuity in the current, no one will deny, but that it is so slight that no instrument less sensitive than a telephone will show it appears to be n by the above experiments. This conclusion being reached, it is difficult to understand how the insulation of the conductor would be more strained by an open coil than by a closed coil machine.

Fig XII

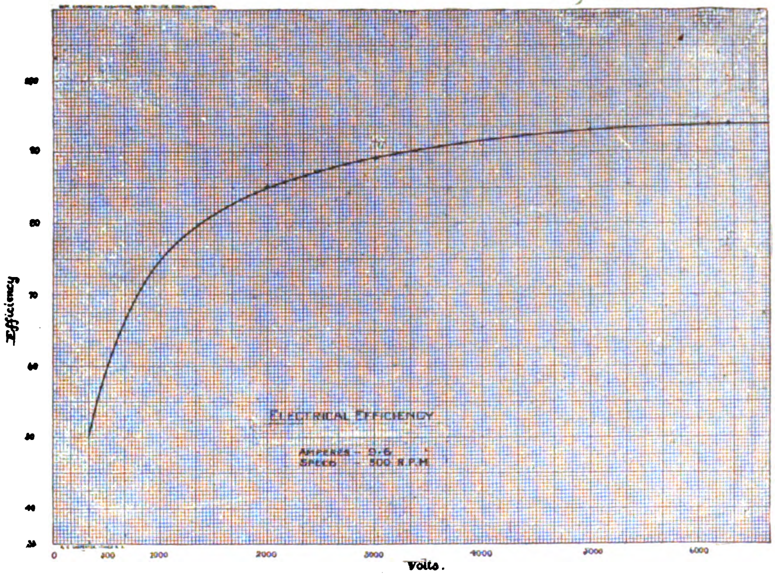

Fig. XIII

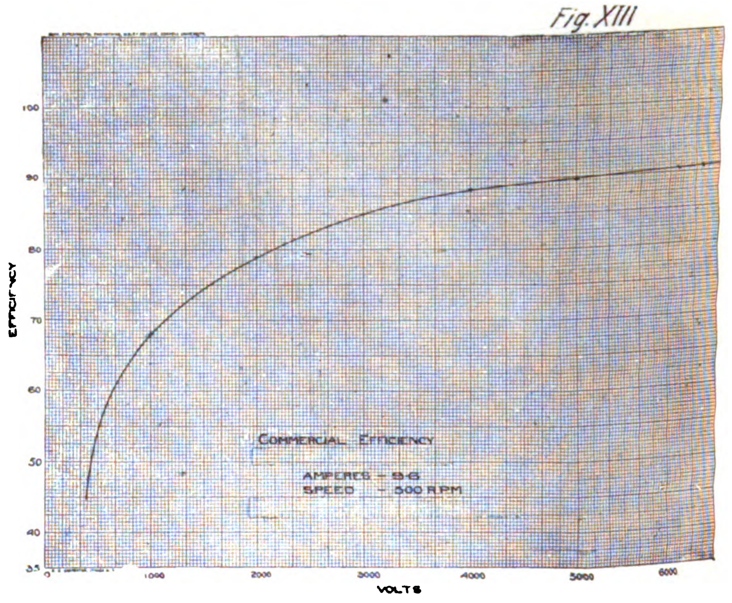


A much more vital question in connection with these large units delivering current to the line at the enormous E. M. F. of 6,000 volts or more is this: What value will the E. M. F. attain in case the circuit is suddenly broken? From a theoretical standpoint, basing our deductions on the manner in which the two types commutate, the open coil machine has largely the advantage.

Opening the circuit is the same in one sense as suddenly throwing a high resistance into the line; and when we do this we shift the point of commutation back under the brush, owing to the reaction of the armature current being reduced. Consequently the bobbin, which should not be cut until after its segment has passed from under the brush, short-circuits the one in parallel with it, and as a result the segment connected with this bobbin carries the arc around to the opposite brush, thereby causing the machine to flash; this short-circuits the armature, and the E. M. F. drops to zero. This flash is not due to the insulation breaking down at any point, but is simply drawing the arc of a short-circuited bobbin part way round the commutator, and in this way is acting like a safety-valve. The machine is not injured in any way, and as soon as the break in the circuit is repaired it is ready to again deliver current to the line. In order to prove this by a practical demonstration and to learn accurately just what value the E. M. F. attained when the circuit was suddenly broken, we made the following experiment: The sparking distances, from 500 up to 9,000 volts, between two carbon pencils, one with a flat end and the other with a rounded one, were accurately determined within a few thousandths of an inch. The results are plotted in Fig. 8. It will be noticed that the curve is almost a straight line, and let me add, it agrees very well with that obtained by De La Rue and Muller, who made quite extensive series of experiments upon sparking distances. The terminals of the 6,250 volt machine were then connected to these carbon pencils, and the greatest distance the current would jump on suddenly breaking the circuit was determined. This distance corresponded to a little less than 8,000 volts, showing that the E. M. F. had risen between 1,500 and 2,000 volts. This can be accounted for by the fact that it takes an appreciable moment of time for the arc on the commutator to be carried from one brush to the other. Owing to each segment extending about 60 degrees around the commutator, the time required to short circuit the commutator is just one-third of what it would be in the closed coil machine; consequently I think the statement that in a closed coil machine the voltage would rise to fully double its normal value, under the same conditions, would be a very conservative one. In fact, I have many reasons for believing that it would go considerably beyond this, providing of course that the insulation of the commutator did not break down. If this occurred, the machine necessarily would be unfit to run again until repaired. This peculiarity, if I may be allowed to call it such, of the open coil machine, is especially important where underground circuits are employed, since a breakdown in the insulation, due to an abnormal rise in the voltage, is something that can only be repaired at considerable expense.

Knowing that some tests on underground circuits would be of interest to central station engineers, I arranged through the courtesy of Mr. E. A. Leslie of the Manhattan Electric Light Company in New York, to make some determinations as to the rise in voltage when a long underground circuit was suddenly broken. A Brush open coil 125-light machine was connected to a twelve mile underground circuit, supplying current to 125 arc lamps. The voltmeter registered 6,850 volts at the machine terminals. The circuit was then broken a number of times with the carbon points in shunt with the break. At first, the carbons were separated by a distance corresponding to 10,000 volts, and this distance was then gradually reduced until the current jumped the air space. This indicated only 5,000 volts. The carbons were then set for 6,000 volts with the result that the current jumped twice in breaking the circuit eight times, showing that we had about reached the limit. It was then decided to try breaking the circuit near the center. Under these conditions, 5,000 volts was the highest reading we obtained, but there was a marked difference in the time of discharge. In the first case there were two discharges in rapid succession within a half second after the break while in the second case fully two seconds elapsed before the current jumped. In both cases there were two discharges before the arc was established, the first one being short and snappy, resembling a static spark. From this it will be seen that the capacity of the circuit more than counterbalanced any rise in voltage due to self-induction of the machine and line. With these results before us we can safely assume that the insulation of a cable will not be overstrained by an accidental break in the line. All these considerations led the company with which I have the honor to be connected to adhere to this, the open coil type of machine, in designing their large units.

Fig. 11 is the characteristic of a 125 light machine. This machine runs at five hundred revolutions per minute, and its rated capacity is 125 50-volt 9.6 ampere arc lamps, or 60 K. W. It will, however, give 6,700 or 6,800 volts without undue heating. Its weight, including sub-base, pulley and regulator, is exactly five tons. The frame proper is made of the best grade of soft gray iron and is cast in three pieces. The two upper caps can be readily removed, thereby giving free access to the armature, which can be taken out and replaced in a very few minutes in case of necessity. The journals are self-oiling and self-aligning, with gauge glasses, so that the amount of oil in the well can always be ascertained at a glance. The field magnet cores are hammered steel, very low in carbon, and showing very high permeability. The pole shoes are steel castings, tapered at the tips to prevent excessive heating due to eddy currents. No. 8 wire is used in the field, which is two sizes larger than on the majority of arc dynamos of other makes. The current per square inch is only 746 amperes, consequently the temperature rises but little even after a 24 hours' run. The armature is of the well-known standard type, the only difference being that, on account of the machine being four pole, four bobbins are connected in series instead of two. We now come to the commutator, that part of all continuous current dynamos which is a source, directly or indirectly, of more perplexity and trouble than all the other parts combined. Three objects were aimed at in designing the commutator for this machine. First, simplicity; second, durability; third, ease of repair. There are three distinct rings, each one of which is built up in sections of thoroughly dried applewood, filled with boiled linseed oil. Over this is forced a mica ring one-sixteenth of an inch thick, and on the sides mica disks protect the wood from the arc. Upon the mica are mounted the brass segments, and on these in turn the copper.

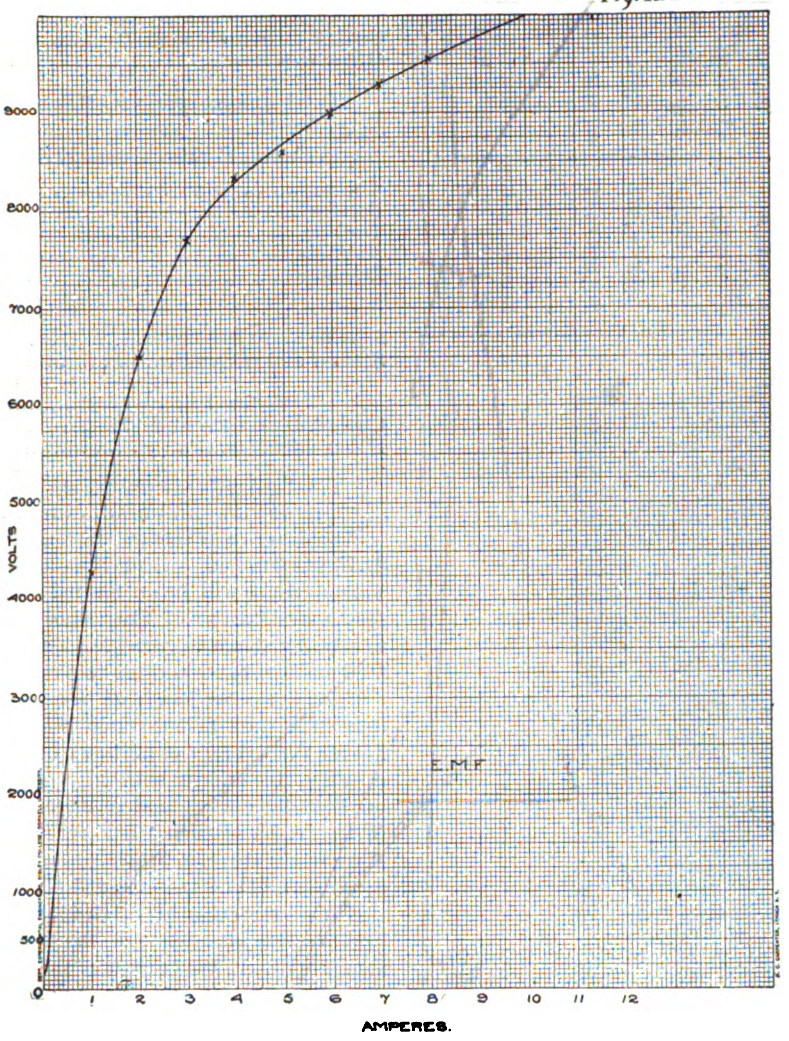
Lignumvitæ blocks 2¾ inches long serve for insulating pieces between the segments. The brushes are the tangential type, the same as those used in connection with all open coil dynamos of this design. An automatic regulator, for shifting the brushes and shunting more or less of the current from the field magnets as the load varies, is fastened to the front of the machine, under the commutator. The small shaft which passes across the front is driven through a worm by a small belt from the armature shaft. On this shaft are mounted two magnetic clutches which are regulated by two relays in the wall controller. The electrical energy consumed in operating the regulator is less than one-tenth of 1 per cent. of the output of the dynamo. The machine is absolutely automatic from one lamp to the full capacity, and the whole load may be thrown on or off with impunity.

Fig. 11 is a characteristic curve of this machine without any regulator. The readings were all taken at the sparkless position of commutation. This is remarkable from the fact that after we get over the bend the curve is almost perpendicular, and is probably the nearest approach to a constant current machine ever attained. By winding more wire on the armature we could have made this machine deliver a constant current of 9.6 amperes at all loads without shunting any of the current from the field, but this would have increased the internal resistance and also have made the machine much less efficient at light loads. By the present method of regulation, we reduced the C^2R loss at quarter load from 4,018 to 3,367 watts, or in other words, we gain almost one electrical horse-power. Fig. 12 is a curve of the electrical efficiency. It will be noticed that this at full load reaches 94 per cent., which is accounted for by the liberal allowance of iron in the armature, thus reducing the reluctance of the magnetic circuit, and by the large size of the wire used on both field and armature.

Fig. 13 is a curve of the commercial efficiency. At full load this is over 90 per cent., and approaches very closely the efficiency of incandescent dynamos of equal capacity, but the most noteworthy point is the high efficiency shown at quarter load.

Fig. 14 is a curve of the machine separately excited, with no current in the armature. The ordinates are the volts at the armature terminals, and the abscissæ the amperes in the field. This is really a permeability curve of the magnetic circuit. By a comparison of the voltage shown here, when there are 9 amperes in the field, with that of the machine when delivering current, can be seen the enormous armature reaction. The curve also indicates a new departure in arc dynamo design, namely, that the magnetic circuit is not worked at nearly as high a point of saturation as in the old types.

Fig. XIV



American Institute of Electrical Engineers.

The 95th meeting of the Institute will be held at 12 West 31st street, New York City, on Wednesday, March 20, at 8 P. M.

A paper will be presented by Prof. Harris J. Ryan, of Cornell University, and Mr. Milton E. Thompson, entitled "A Method for Preventing Armature Reaction."

Storage of Energy Essential to Economy of Working in Central Stations*—III.

BY N. W. PERRY, E. M.

THE FEED STORAGE SYSTEM.

According to this system, approximately the whole of the feed water required for the twenty-four hours is pumped into the feed tanks during the time of light loads; so much of it as the boilers require during this time is supplied from the tanks, and the rest (which will be that wanted during the heavy load time) is retained in the tanks and heated up by the surplus steam during the said light load time up to or nearly to the temperature of the steam in the boiler, viz., 347°, and is used as boiler feed during the heavy load.

By this method of working, the duty required from the boilers will be considerably lessened, for, while during the time of maximum load they will still be required to supply steam at the rate of 6 inches × 27,500 = 165,000 pounds per hour, the total heat which they have to gather from the fuel and impart to the water will be lessened by the increase in temperature of feed from 100° to 347°, a gain of 247°. The total heat of 180 pounds absolute steam being 1,219°, we have the maximum heat to be supplied by the boilers at present $= 165,000 \times (1,219° - 100°) = 165,000 \times 1,119 = 184,635,000$ units of heat hourly. Whereas with the feed storage the maximum required $= 165,000 \times (1,219° - 347°) =$ only 143,800,000 units. In other words, $\frac{1}{4.53}$ of the maximum work of the boilers is avoided and a corresponding number can therefore be laid off.

During every stage of the heavy load, with 347° feed, the same proportion of boiler work is saved, and this is illustrated on the diagram by the dotted curve and figures, 4.67 inches representing the maximum required work with feed storage, against 6 inches without, equal to a gain of 1.329, which is $\frac{1}{4.53}$ of 6.11, or 22 per cent.

The dotted curve of required boiler duty, during the seven and a half hours under the new conditions, is, therefore, quite definite as to form and also as to area enclosed by it. The dotted curve during the remaining sixteen and a half hours of light load must be such that the deficiency in work during these hours equals the excess of work during the heavy load time, and the area it encloses is, therefore, quite definite, while its form depends upon the rate of working both as to firing and to feeding, and this form can with moderate care be made to assume that shown, which will give a maximum amount of work measuring 0.73 inch, so that the ratio of maximum to minimum becomes six to one, viz., $\frac{4.671}{.73}$, instead of the present 23.4 to 1, a reduction of irregularity of working which must necessarily be beneficial to the general working of the boilers and must effect a considerable saving of fuel.

The required tank capacity is easily estimated, being the total of water evaporated for seven and a half hours, viz., $(1.624 + 2.465) \times 27,500 \times 7\frac{1}{2} = 843,150$ pounds. Taking the size of tanks proposed by Mr. Halpin of 8 feet in diameter by 30 feet in height and allowing for their not being emptied within some 3 feet of the bottom, so as to leave room for deposited mud, etc., they may each be taken as containing a working quantity of 75,000 pounds of water, so that full eleven of them would be wanted, viz., $\frac{843150}{75000} = 11.24$.

The cost of these, including fittings and coverings, I will take at £500, which I believe to be a liberal estimate, so that if we allow for a reduced number of boilers, according to the reduced maximum work required for them, we shall have the cost of boiler plant on this system :

---

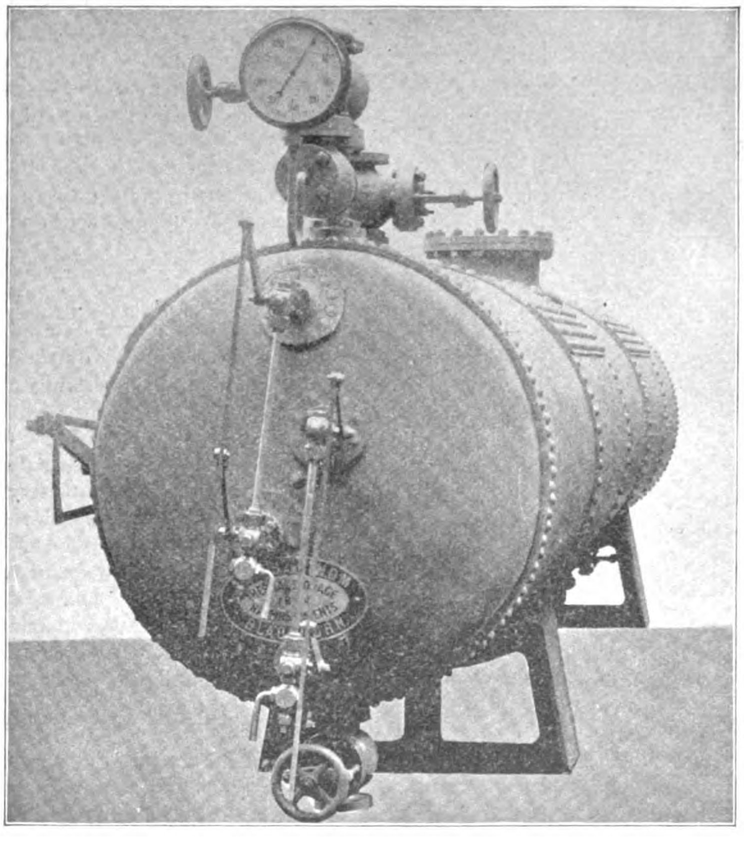
*Read before the National Electric Light Association at its Eighteenth Convention, held at Cleveland, O., February 19, 20 and 21, 1895.

Boilers, $\frac{4.671}{6}$ × £30,000 =	£23,360	
Tanks, 11.24 × £500 =	5,620	
Total	£28,980	

COMBINED FEED AND STEAM STORAGE.

The same authority gives the estimated cost of this as follows: The saving of boiler duty, due to the feed storage only, is the same as for the previously taken case of feed storage, and is represented by the area enclosed between the full and the dotted curves during the seven and one-half hours of heavy work, and the extra steam to be produced is represented by the area enclosed between the dotted curves during the seven and one-half hours and the straight mean lines for twenty-four hours. This extra steam will amount to 1.60 × 27,500 pounds × 7½ hours = 330.000 pounds requiring 330,000 × (1,219° — 876°) = 278,190,000 heat units. The water in tanks giving us, as before, 59 heat units per pound in cooling, we shall want $\frac{278190000}{59}$ = 4,715,100 pounds of water, which will require 63 tanks. Add tanks for feed storage as before = 11 = total of 74.

The boilers will cost as for steam storage	£8,526
The tanks will cost 74 × £500 × 1.05	38,850
Total cost	£47,376



HALPIN'S THERMAL STORAGE TANK.

This is over 20 per cent. less cost than for the steam storage alone. It is not more complicated, since the feed and the steam may be stored in the same tanks; and it has the additional advantage of supplying nearly clean water to the boilers, as has the simple feed storage system, and the work on the boilers is uniform for the 24 hours, which will necessarily produce a considerable economy of fuel.

Comparing now the above four modes of working the boiler plant of such an installation as the Berlin electric station and tabulating Mr. Schonheyder's results we have the following tabular view :

	Present System.	With Feed Storage.	With Steam Storage.	With Feed and Steam Storage.
Steam pressure	115 lbs.	115 lbs.	115 to 250 lbs.	115 to 250 lbs.
Feed temperature	100°	100° to 347°	100°	100° to 347°
Rate of working	24.4 to 1	6 to 1	Uniform.	Uniform.
Feed water	Dirty.	Clean.	Clean.	Clean.
Cost of boilers	£50,000	£23,360	£8,526.	£8,526
Cost of tanks	....	£5,620	£50,925	£38,850
Total cost	£30,000	£28,980	£59,451	£47,376

All of the above was embodied in an article of mine published in the *Western Electrician* of January 5, 1895.

Let us see how the data here presented, when interpolated in the case we assumed in starting out, affect the results:

WITH FEED STORAGE.

Engines	$274.56
Boilers	113.47
Buildings	120.00
Dynamos	120.00
Tanks	29.32
	$657.35

Allowing 10 per cent. for interest, depreciation and maintenance on the investment, exclusive of tanks—which is the same as before—and only 5 per cent. on the tanks, we have:

$628.01 at 10 per cent	$62.80	
29.32 at 5 per cent	1.47	
Total fixed annual cost		$64.27
Coal	$20.00	
Other expenses as before	13.31	33.31
Total annual cost per electrical horse-power		$97.58

WITH STEAM STORAGE.

Engines	$274.56	
Boilers	37.13	
Tanks	236.70	
Buildings	120.00	
Dynamos	120.00	
	$788.39	
$551.69 at 10 per cent	$55.17	
$236.70 at 5 per cent	11.83	
Total fixed annual cost		$67.00
Coal, 2.21 pounds at $1.75	$16.93	
Other expenses	13.31	30.24
Total annual cost per electrical horse-power		$97.24

COMBINED FEED AND STEAM STORAGE.

Engines	$274.56	
Boilers	37.13	
Tanks	180.37	
Buildings	120.00	
Dynamos	120.00	
	$732.06	
$551.69 at 10 per cent	$55.16	
$180.37 at 5 per cent	9.02	
Total fixed annual cost		$64.18
Coal, 2.21 pounds at $1.75	$16.93	
Other expenses	13.31	30.24
Total annual cost per electrical horse-power		$94.42

The above calculations show that with coal at $1.75 per ton and a load line such as that assumed there will be an annual saving with the feed water storage of $20.20 per horse-power annually, by steam storage $20.54, and by combined feed and steam storage an economy of $23.36.

If, on the other hand, we assume coal to cost double this, or $3.50, which would perhaps be nearer the average conditions obtaining in this country, our energy without storage would cost us $148.40 per annual electrical horse-power. With feed storage, $117.58; saving $30.82. With steam storage, $114.27; saving $34.13. With combined, $111.35; saving $37.05.

Being aware that Mr. Halpin had already put into practice his system of thermal storage, immediately upon the receipt of the invitation from your president to address you upon the subject of storage of energy, I solicited from Mr. Halpin information in regard to the results obtained. The time allowed for a reply was exceedingly limited, but he was kind enough to send me a letter, together with the two photos and diagrams which are here reproduced.

The half-tones are of small feed storage tanks used in a plant already erected, represented in sketch No. 2. The two boilers shown in sketch are "Cornish," 5 feet 6 inches diameter by 26 feet 6 inches long, and have flues 2 feet 9½ inches diameter and 5 feet 6 inches grates with heating surface of 500 square feet and a grate area of 15 by 35 feet. But Welsh coal is used, containing about 15,000 Board of Trade units, and the plant drives the laundry, the electric lighting, duplex pump for elevators, the whole of the radiators, provides steam for cooking in the kitchen, and supplies the hot water service of a large hotel.

The feed is delivered from the town's water supply into the tank under the feed water heater, and by means of duplex pumps it is passed through the feed water heater, where it is raised to a temperature of about 200° Fahrenheit, and from there it is forced into the top of the thermal storage vessel, where the feed pipe delivers horizontally into the steam space, towards the back end of the vessel, or away from the firing end of boilers. The blow-out for the dirt deposited in the thermal storage vessel is also at the back end, and this blow-out is connected directly with the main blow-out in front of boilers.

The feed passes along the thermal storage vessel, and is led out near the firing end of boilers by a pipe standing about nine inches above the bottom of the vessel. From here it gravitates into the boilers, the quantity being regulated by these valves.

There is a pipe from the steam space of boiler direct into the top of the thermal storage vessel, so that there is always the same steam pressure between the boiler and thermal storage vessel, and the feeding into the boiler is effected by the head of water in the thermal storage vessel above the boiler.

He writes:

"I was obliged to start the plant before the makers had completed the thermal storage vessel and its connections, and when the boiler working them was emptied it was found to contain thirty-five buckets of sediment and incrustation.

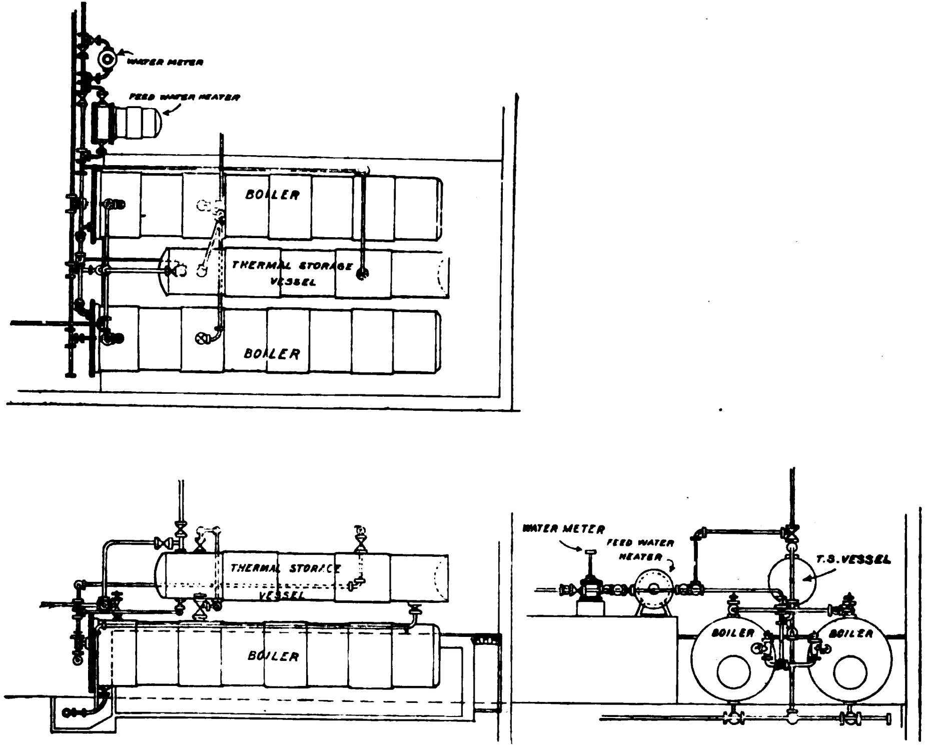


FIG. 2.

ARRANGEMENT OF STEAM PLANT WORKING UNDER HALPIN'S FEED STORAGE SYSTEM, SUPPLYING STEAM FOR LIGHTING, HEATING, COOKING, ETC., IN LARGE ENGLISH HOTEL.

"After the feed storage was got to work one boiler ran twenty-two days and nights continuously, and on opening out it was found absolutely devoid of scale or dirt.

"I caused two tests to be made of eighteen hours each, during which the coal was accurately weighed and the water measured through a meter I had previously checked, with the following results:

"When working without thermal storage the evaporation reduced to 'from and at 212° Fahrenheit' was equal to 10.95 pounds of water per pound of coal, and on the second test, when the thermal storage was at work, the evaporation was raised to 12.21 pounds.

"Of course, you must bear in mind that this particular apparatus was only designed for feed storage, as *steam* storage was not required under the special conditions which had to be dealt with in this case.

"Sketch No. 3 of the storage vessels, to work in connection with refuse destructors, shows four thermal storage vessels, the number required in this case.

"You will, of course, observe that any possible effect of radiation, about which I am not at all frightened, is minimized, as the cylinders here radiate against each other, so that only one-quarter of the total surface, or, say, one cylinder, will be under the influence of losses from radiation.

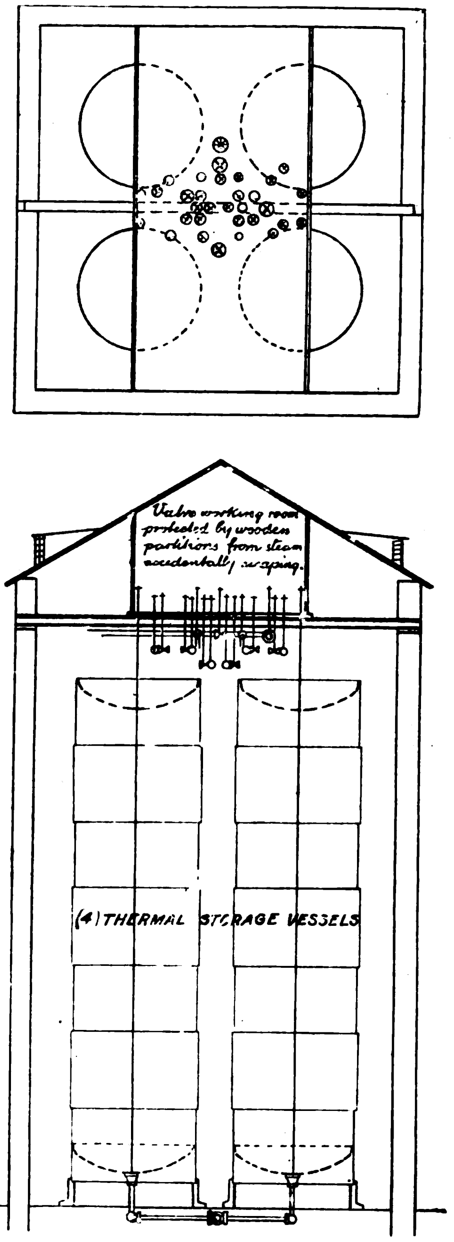
"I have arranged this plant so that there is a wooden gallery in the roof, and into this gallery *all* the various handles are brought for working the apparatus. I have taken this precaution so that should any joint break the men in charge are perfectly safe, and being in the gallery they can control the valves and blow the vessel off, any escaping steam passing out through louvres in the roof. The boilers for this plant are not shown.

"You will observe the thermal storage vessels are completely finished in the riveting machine, not a single rivet being put in by hand, and owing to the form of the dished ends there is not a single stay in the whole vessel, so that they are absolutely free to expand in any direction without doing injury by tearing themselves to pieces. All the valves, etc., are arranged so that any one or all vessels can be cut out of use."

In conclusion I will say that, of all the methods of storage available, the storage battery would, on theoretical grounds, be the best, because of its forming the last link in the chain, thereby giving the economies of continuous working to all that precede. Unfortunately, it involves such large losses in itself as to nearly if not quite nullify the advantages it would otherwise present. And again, its heavy cost above all other methods renders it unavailable in any complete storage project unless fuel is dear.

We are therefore compelled to go back of the engine for our equalization schemes and put up with the losses due to variable load upon all that follows. Fortunately the losses which we can overcome at this early stage are quite considerable, and we have a number of methods at hand. Of these the gas engine—involving a gas storage—seems to give the best results. Very closely following this comes Halpin's combined feed and steam storage, followed by feed storage and steam storage. Below is given, in tabular form, the cost to produce for one year one electrical horse-power, with coal at $1.75 per ton and at $3.50 per ton; also, the saving effected by the various methods over present methods in a station having a mean load 25 per cent. of its maximum:

	RECAPITULATION.		SAVING EFFECTED.	
	Coal $1.75 per ton.	Coal, $3.50.	Coal, $1.75.	Coal, $3.50.
Present method, steady load........	$48.68	$65.62	......	......
Present gas engine..	88.28	103.61	$29.50	$44.79
Combined feed and steam storage......	94.42	111.35	23.36	37.05
Feed storage.........	97.58	117.58	20.20	30.82
Without storage, load factor 25 per cent...	117.78	148.40	......	......
Steam storage........	97.24	114.27	+ 20.54	34.13
Complete battery storage.............	128.18	145.74	— 5.35	+ 2.66



Valve working room protected by wooden partitions from steam accidentally escaping.

FIG. 3.

HALPIN'S COMBINED FEED AND STEAM STORAGE SYSTEM, IN CONNECTION WITH REFUSE DESTRUCTORS, TO SUPPLY STEAM TO A MUNICIPAL LIGHTING STATION.
(*Boilers not shown.*)

Detroit Lighting Plant to Start.

It is reported from Detroit that there will soon be six 100 light dynamos, two engines and four 300 horse-power boilers ready for operation in the plant. There are 200 lamps strung and circuits tested in the underground district, and 23 lighting towers equipped. Besides this there are about 50 lamps ready to start outside the underground district. The incandescent plant is all wired and 2,000 incandescent lamps will also be lighted when the wheels of the plant first start up.

Lake City, Minn.—The question of putting in electric lights is to be submitted to the voters this spring.

ARC LAMP NEWS.

Mr. R. B. Corey has concluded an arrangement with the General Incandescent Arc Light Company by which Mr. Corey will be the sole selling agent of the product of the Bergman factory, the latter manufacturing, in addition to their present well known line of lamps, imported carbons, etc., all the various styles of Knight lamps.

Mr. Corey is established in his new offices in the Havemeyer Building, and is now prepared to give prompt attention to the wants of his innumerable friends and customers.

More Telephone Competition.

Messrs. W. D. Jameson & Co. have opened offices at 150 Broadway, New York, as general United States agents for the Gerson telephone, made in Philadelphia. Their line comprises apparatus for all services, which is sold outright.

Personal.

Mr. Herbert Wagner, of the Wagner Electrical Company, St. Louis, was in Philadelphia last week.

Mr. C. H. McIntyre, of Newark, accompanied by Mrs. McIntyre, is spending a couple of weeks in Florida.

Mr. W. J. Clark, of the General Electric Company, whose health has not been good for several months, has gone abroad to recuperate, and will spend most of his time in Italy and Southern France.

Among the Buffalonians in town last week were Messrs. Charles L. Huntly and Tracy Becker, the latter being the counsel of the Buffalo G. E. Company.

Mr. John B. Wallace, of the Wallace Electric Company, who has been in the East for several days, has returned to Chicago.

Mr. P. C. Ackerman, of the American Electrical Works, leaves New York for a Western trip to-day.

Mr. Brainerd Rorison, of the Ft. Wayne interests, arrived home from Europe last week. Mr. Charles S. Knight, manager of the Ft. Wayne Electric Corporation was also in the city.

Mr. James Cummings, of the firm of Cummings & Engleman, Detroit, is a New York visitor this week.

Mr. P. H. Alexander has returned from a successful trip in the interests of the Electric Selector and Signal Company.

Mr. M. M. Hayden, now with the National Carbon Company, has been shaking hands with many New York friends this week.

Mr. G. H. Van Voorhis, who was for a long time with W. R. Mason in Chicago, is now located in New York with Messrs. W. D. Jameson & Co., 150 Broadway.

The Brooklyn Electrical Society in Permanent Quarters.

The members of the Brooklyn Electrical Society have opened their new laboratory and reading rooms at 370 Pearl street. In these rooms are soon to be carried on several interesting experiments in the latest electrical inventions, while students of the science will be able to find the latest electrical literature. An electrical library will be inaugurated for the use of the members, and a novelty in the shape of a classified catalogue library is to be introduced.

The society will hold lectures in the Edison Assembly Rooms every Tuesday evening.

Membership in the Brooklyn Electrical Society is open to all interested in the study of electricity, and communications should be addressed to the chairman of the Membership Committee, Thomas A. Bamford, 370 Pearl street, Brooklyn.

COMMUNICATION.

PERKINS LAMPS.

To the Editor of ELECTRICITY.

DEAR SIR: We find a statement in your issue of March 13 which we desire to correct. On page 126, top of middle column, under the heading "Another Perkins Lamp," a statement is made to the effect that Mr. C. G. Perkins will shortly begin the manufacture of the Perkins incandescent lamp. We are not definitely informed as to the plans of Mr. Perkins, but have heard that he intended to manufacture incandescent lamps. However, we desire to state that the right to make "Perkins" incandescent lamps, or any lamp in which the name of "Perkins" is associated in any manner, belongs exclusively to this company, and we would, therefore, ask you to correct the paragraph as above. The only "Perkins" lamps to be obtained are manufactured and sold by this company. We presume the statement in your paper of the 13th was made inadvertently, but desire it corrected before it has been too widely spread. Thanking you for your courtesy in advance, we are very truly,

THE PERKINS LAMP COMPANY,
A. D. CLAFLIN, Treasurer.

Boston, March 14, 1895.

LEGAL NOTES.

Thomas J. Mooney, receiver of the National Electric Manufacturing Company of Troy, N. Y., has brought suit against the Wisconsin Company of the same name (also in the hands of a receiver), on a claim of $25,000, which was disputed in the settlement between the companies, who were allied to each other.

An execution for $65,887 has been received by the sheriff of New York, against the New York Electrical Engineering Company, in favor of Wareham & Hughes for balance due on the construction of an electrical railway from Pittsburg to Munhall Station, Penn. The total amount of the contract was $94,000. The firm claimed that it did work to the amount of $84,000 and received $19,050 in payment. Judge Giegerich has appointed R. A. Stackpoole receiver for the company.

The electric light plant at Paducah, Ky., owned by the Consolidated Engineering Company of St. Louis, has been attached by the Standard Electric Company of Chicago, for $4,900.15. The city owes $12,000 to the St. Louis Company.

General News.

What is Going on in the Electrical World.

Spartanburg, S. C.—A survey has been made for an electric railway from this city to Glendale and Clifton.

Independence, Iowa.—At the city election on the 5th there was a large majority in favor of the city erecting an electric light plant.

Shelbyville, Ill.—Trout Bros. have been granted a franchise to establish an incandescent electric lighting system in this city.

Lake City, Minn.—The question of bonding the city for an electric light plant will be submitted to the voters at the charter election on April 2.

Carbon, Ind.—The city council has accepted the Fox Brothers' proposition to put in an electric light plant here and furnish the town with electricity.

Lynchburg, Va.—The city council has by vote authorized an issue of $60,000 of 5 per cent. city bonds to defray the cost of establishing an electric light plant.

Hudson, N. Y.—The Kinderhook and Hudson Railway Company are considering the advisability of using electricity on their line. Steam is at present employed.

Niles, O.—The council has passed the ordinance granting the Mahoning Valley Electric Railway Company a franchise. This line will connect Niles and Youngstown.

Woods, Ore.—A subsidy has been raised here to build an electric railway to Ocean Park, and the people are discussing the question of waterworks and electric lights.

Cleveland, O.—The property of the Cleveland Gas Fixture Company was purchased lately in the Probate Court by the Cleveland Gas and Electric Fixture Company, a new concern.

Jackson, Tenn.—The city council has decided to have an electric light plant of its own to light the streets. An arc plant will be put in and operated in connection with the waterworks.

Rossville, Ill.—The village council has granted to Frank L. Stewart, of Rossville, a franchise for an electric light plant, a telephone exchange and an electric street railway.

Portland, Me.—A survey has been made for the new electric road in this city by representatives of the firm of Hodges & Harrington, of Boston, who are the supervising engineers for all the construction.

Annapolis, Md.—The city counsellor has been instructed by the council to prepare a contract and ordinance granting a street franchise to the Annapolis, Brighton Beach and Bay Ridge Electric Railway Company.

Abilene, Kan.—The Abilene waterworks and electric light plant has been sold at master's sale as part of the assets of Coffin & Stanton, New York. It brought $22,700 and was bought in by the bondholders' committee.

Kansas City, Mo.—The first bondholders of the Northeast Street Railway Company are considering the advisability of selling the road, now under foreclosure, in April, and buying it in with the purpose of reorganization.

Holton, Kan.—The electric light plant owned by John I. Myers and James H. Lowell, of Holton, and Dr. M. B. Smyth, of Springfield, Mo., was totally destroyed by a fire here on the 4th. The plant was valued at $14.000.

Indianapolis, Ind.—The bill allowing electric street railway companies to supply steam, light and power passed both branches of the Legislature; also the bill authorizing cities and towns to operate their own electric light plants.

Concord, N. H.—The bill in relation to the incorporation, organization and regulation of street railway companies, and authorizing the use of electricity as motive power by existing steam railroads, has passed the Senate.

Mt. Clements, Mich.—The required bonds for the electric road to Detroit has been raised by the people of Mt. Clements, and the electrical equipment has been ordered. The builders promise the best electric road in America.

Los Angeles, Cal.—The holders of the bonds of the Los Angeles Consolidated Electric Railway Company have decided to assume the control of that organization, to greatly improve its plant and to endeavor to place the road upon a paying basis.

Middletown, Conn.—The work of constructing the Middletown and Cromwell electric road is to be commenced in a few weeks and the company, of which Israel A. Kelsey of West Haven is president, will expend about $50,000 in completing the road.

Bristol, Tenn.—The sale of the Bristol-Goodson gas and electric plant to S. C. Hurt & Son, of Lynchburg, Va., and their Bristol associates, at the price of $20,600, has been confirmed. The new company will spend several thousand dollars in improving the plant.

Elwood, Ind.—The Elwood Electric Street Railway, Light and Power Company, whose buildings and cars were destroyed by an explosion last December, have completed the work of rebuilding, and will resume operations at once. The expense of rebuilding was $40,000.

Fall River, Mass.—The Barrington and Warren Railroad Company has applied to the Rhode Island General Assembly for a charter which if granted and the road is built will give a complete chain of trolley roads between Fall River, New Bedford, Providence, Pawtucket and Central Falls.

Auburn, N. Y.—President C. D. Beebe of the Auburn City Railway and President Thomas Craig of the Seneca Falls and Waterloo road have a project under consideration which they hope to see accomplished, to wit, the connection of Auburn with Geneva and Syracuse by electric roads.

West Point, Miss.—Hosmer & Bell, of this city, have just completed an incandescent dynamo at their foundry and machine shops. This is said to be the first dynamo ever manufactured south of the Mason and Dixon line. Its capacity is 400 incandescent lights.

Birmingham, O.—The road to be built by the Milan, Birmingham and Elyria Electric Railway Company will run from Milan through Berlinville, Florence, Birmingham, Henrietta and South Amherst to Elyria. The capital stock of the company is $100,000.

Boston.—A. W. Mitchell, of Crescent Beach, Mass., has patented a controller for electric cars which does away with the brake and power cranks, substituting in their place a large iron wheel which does the work of both. The car is started by turning the wheel to the left when the brakes are released and the power is put on. A turn to the right reverses this order, and the car is brought to a stop.

Milford, Conn.—Francis W. Marsh, Sherman H. Baldwin, J. D. Brown, Howard H. Scribner, John W. Thompson, Frank L. Rogers and Chas. W. Beardsley have asked the Legislature for incorporation as a company to build and operate an electric road in Milford with an extension to Stratford and Bridgeport, and thence to Seaside park. This is the first electric company in the field in Milford.

Chicago.—The plant of the Chicago Electrical Supply Manufacturing Company, which has long been idle, is to be removed to Marion, Ind., and put in active operation. The work of erecting the necessary buildings and removing the machinery has already been commenced, and it is expected to have the plant in operation within sixty days. Employment will be given to several hundred men.

McKeesport, Pa.—The *Times* of the 9th inst. has the following: "Next Monday the three departments of the Westinghouse Electric Company's plant at Brinton that have been idle will resume and the works will then be on full. This week 3,000 men were at work, next week the number will be increased to 4,000. The Westinghouse Air Brake Works at Wilmerding are running double turns, employing 3,200 workmen."

Staten Island, N. Y.—The Staten Island Belt Line Railroad Company's property, appurtenances, equipments, etc., have been purchased by J. P. O'Brien, of the Thomas syndicate, for $75,000.—The Edgewater board of trustees have granted the application of the Midland Railroad Company to change the motive power on the line from Stapleton to Concord from horses to electricity. The trustees also granted the Staten Island Interior Company rights of way over a number of streets.

Buffalo, N. Y.—A company is being organized here to build an electric road between this city and Hamburg, the estimated cost of which is $100,000. The road will be nine miles long. Among the Buffalo men interested are William Ellwood, S. H. Koopmans, John O'Brian, L. L. Long, James E Curtiss and R. L. Banta. The Hamburg men interested are Hon. Thomas L. Bunting, George M. Pierce, Jacob Peffer and H. Spencer. Pittsburg and Titusville men are also interested.

Washington, D. C.—A force of men are at work on the construction of the new underground electric system that is to be used on the Ninth street section of the Metropolitan road. The power house for this new plant has already been built, and the engines have been in working order for some weeks past. The street work will now be pushed with all the energy that can be put into it by an experienced contractor, and he promises to have the new line in running order within sixty days.

Green Bay, Wis.—By an agreement between the Wisconsin Interurban Railway Company and Elmore & Vanderzee of Green Bay, rival aspirants for franchises to build an electric line from Neenah to Kaukauna, the Wisconsin company withdraws and leaves the Green Bay gentlemen in possession of the field for ninety days. If they can get the franchises and raise the money within that time they are to build the road. If not, they are to step aside and leave the field clear for the Wisconsin Interurban Railway Company.

Pittsburg, Pa.—An electric railway scheme that comprehends the tunneling of Mt. Washington and supplying quick transit to all the territory lying south of the Monongahela River as far out as Carnegie and West Liberty is to be carried out in a short time, the project being in the hands of men who have the means and the spirit to push the matter to completion. James M. Bailey is at the head of the company. The route includes a number of suburban villages and will enter Pittsburg by way of the Smithfield street bridge.

Hartford, Conn.—The fire board has decided to replace the present liquid batteries in the battery room with a storage battery system (chloride accumulators), complete, with switches, rheostats, etc., including a spare battery for each of the four fire alarm circuits. The system is the same as that now being adopted by the Western Union Telegraph Company in all its offices. The total cost will be $767 for the equipment, which will last five years. The Hartford Electric Light Company has agreed to furnish the current for charging the batteries for $40 per year.

Atlanta, Ga.—A company has been organized here whose object is to erect an electric generating plant on the Chattahoochee River at an available point for the development of water power, and transmit electric current to this city for power and lighting purposes. The principal promoters are E. A. Thornton, James D Collins, Evan P. Howell and John A. Grant of Atlanta, James Swann, Jonathan H. Vail and Hugh R. Garden of New York and Richard N. King of Dayton, O. The capital stock of the company will be $100,000 actually paid in with power to increase the same to any amount not exceeding $2,000,000.

Baltimore, Md.—The Susquehanna River Electric Company, which was recently incorporated in Baltimore, has purchased the plant of the Susquehanna Water Power and Paper Company, near Conowingo. With this purchase the electric company now controls about six and a half miles of water-front on the Susquehanna river, having a fall of 100 feet and affording excellent power to generate electricity. The buildings of the Water Power and Paper Company will be converted into an electric plant at once. All the present machinery will be taken out and the interior remodeled into a power-house. The promoters of the electric company say they expect to have their plant in operation within a year.

New York.—A fire in the building 33 35 South Fifth avenue on the 13th inst. destroyed all the apparatus used by Mr. Nikola Tesla in his electrical experiments, together with models, drawings, etc., of inestimable value to him and some of which it will be impossible to reproduce. The money value of the articles consumed belonging to Mr. Tesla was at least $15,000, but this he considers of small account as compared with the trouble he will be put to in restoring a collection of working materials, including many delicate instruments used in his extraordinary experiments, which has taken him several years to devise or otherwise obtain. Much sympathy has been expressed in the public press and among electrical people for Mr. Tesla, who was greatly affected by his loss, but promises to continue his work with redoubled ardor.

Tacoma, Wash.—The project of the White River Water Power Company, to erect a water power plant in the Stuck Valley capable of developing 50,000 electrical horse-power, is second only to the Niagara Falls enterprise in extent and importance. The location chosen for the generating station is on the White River, ten miles east of Tacoma and twenty-eight miles south of Seattle, and power will be transmitted to both of these cities and to a number of contiguous villages. The amount estimated for present needs is 25,000 H. P. The White River Water Power Company is already incorporated, with a capital stock of $2,000,000. Preparations have been made to begin work at the opening of the season, and it is expected to finish construction and have the entire plant in operation before the end of the year. The equipment is to be furnished by the Westinghouse Electric and Manufacturing Company, who are now putting in the great dynamos at Niagara Falls.

Pittston, Pa.—The electrical hoisting plant that is being built at the Priceburg mine of John Jermyn is a matter of interest to mining engineers, on account of certain difficulties to be overcome in applying electricity to hoisting apparatus, the chief one being the dead resistance of a train of cars at the foot of a slope or a loaded carriage at the bottom of a coal shaft. The hoisting apparatus in question consists of two motors, the armatures of which are not connected except by means of the gearing on the second shaft. The principal reason for this arrangement is that one motor can be used should the other break. The great advantage of the electric hoist at Priceburg lies in the fact that it is located 5,000 feet from the power house, upon the side of a mountain, where it would be practically impossible to use a steam plant, there being no water convenient. The next step will be the application of electricity to hoisting from shafts. This will be the critical test for the new power so far as the mining industry is concerned.

Albany, N. Y.—In the Assembly a bill has been introduced to incorporate the Niagara River Tramway Company, with power to associate with any other persons or company in Canada not having banking or insurance power. The company has a capital of $50,000, and is to construct and operate a tramway over, across and along the Niagara River in Niagara County and from the east or American side of that river to the opposite shore in Canada. John A. Merritt, John E. Pound and George W. Pound, of Lockport; George Baltz, of Buffalo; L Clarke Raymond, of Welland, Ontario; Robert N. Campbell, of Niagara Falls; A. Monte Cutter, of New York City, and John Fleet and Joseph Tait, of Toronto, are named as commissioners to open the subscription books. The company proposes to operate cars by electricity on a cable suspended in front of the Falls, between the American and Canadian sides, and already has the right to do so from the Canadian Government.—Gov. Morton has signed Assemblyman Higbie's bill exempting the counties of Richmond and Queens and the village of White Plains from the provisions of the act authorizing the village boards of trustees to contract with electric light companies organized in this State for lighting village streets and public grounds.

Telephone and Telegraph.

The Bell Telephone Company has reduced its rates for the use of 'phones in Philadelphia to $50 a year as the minimum instead of $120, the former charge.

The county court has granted the St. Louis County Electric Light and Power Company the right for twenty years to erect and maintain its wires upon the poles of the St. Louis County Telephone Company.

Paul Minnis has applied to the city council of Mobile, Ala., for a franchise to operate a telephone exchange in that city.

The new telephone company at Petersburg, Va., has completed its organization by electing the following officers: President, William B. McIlwaine; vice-president, E. A. Hartley; secretary and treasurer, R. D. Gilliam; directors: T. S. Beckwith, John O'Connor, T. F. Heath, W. S. McCance, T. H. Woody, Louis C. Wright, A. Rosenstock.

Wm. N. Cannon, of Binghamton, has made arrangements to put in a telephone system at Deposit, N. Y. About twenty miles of wire will be strung.

The Central New York Telephone and Telegraph Company have applied to the city council of Utica for permission to construct underground subways in the streets.

Marshfield, Wis., is now connected by telephone with the outside world by a private line to Aspin, where it connects with a line to Grand Rapids. Theodore Springborn, the builder of the new line, will next build a line from Marshfield to Stratford and another to Nasonville.

At a hearing before the Assembly Committee on Gas, Electricity and Water Supply, held at Albany, N. Y., on the 12th inst., Mr. Rush C. Taggart, appearing for the Western Union Telegraph Company, spoke in opposition to the Wieman bill proposing a reduction of telegraph rates. In the course of his argument, Mr. Taggart said: "The present rate for sending a message of ten words is 25 cents. To reduce the rate would mean an impairment of the capital stock of the Western Union Company, which was now paying 23 3-10 cents for every message of ten words sent."

The stockholders of the Alexandria Telephone Company, of Alexandria, La., have elected the following officers: President, Thos. Clements; vice-president, J. C. Ryan; secretary and treasurer, L. A. Stafford. It is the intention of the company to construct telephone lines in Alexandria and the surrounding country.

A franchise asked for at Toledo, Ohio, by the American District Telegraph Company, has been approved by the Committee on Railroads and Telegraph. It places the company on the same footing as other companies using electric wires in Toledo.

The Niagara Mutual Telephone Company has opened subscription lists at Tonawanda, N. Y. The promoters of the company are local business men who consider the present telephone rates exorbitant and believe that a local corporation could furnish as good service for much cheaper rates. As soon as 150 subscribers are secured the company will take steps toward incorporation.

The Hudson River Telephone Company reports gross revenue for the year $260,977, expenses $178,857; net revenue $82,120. A comparison with the report for 1893 shows an increase in the gross revenue of $11,147.44, a decrease in the expense account of $8,369.33, and a gain in net revenue of $19,516.77.

The movement for the installation of a new telephone system on Staten Island is being vigorously pushed by the projectors. The new enterprise is called the Staten Island Automatic Telephone Company. It has secured the right to erect poles and wires from the New Brighton trustees, and has made application to the Edgewater board. The representatives of the company state that 150 subscribers have been secured in New Brighton.

The Gamewell Fire Alarm Telegraph Company of Newark, N. J., has been awarded the contract for the new police patrol telegraph system at Rochester, N. Y., the cost to be $2 100. The Gamewell Company has also signed a contract to put in its fire alarm system at Amsterdam, N. Y.

The superintendent of the Central Union Telephone Company has lately been in Belvidere, Ill., endeavoring, it is said, to make contracts with the residents, agreeing to furnish telephones free. The contract calls for $18 per year, but when the contract is signed the subscriber is presented with a receipt for one year. Belvidere was one of the first towns in the country to put in an opposition telephone exchange, and this action on the part of the old company is intended to cripple the others.

The American Telephone and Telegraph Company of New York City has filed with the Secretary of State at Albany a certificate of increase of its capital stock to $12,000,000. The amount of capital of the company actually paid in is $7,500,000, and the whole amount of its debts and liabilities is $3,019,005.

At Dubuque, Iowa, several hundred business men have, it is reported, signed contracts to take the Harrison telephone for five years. The Bell Company, which has 500 subscribers at $48 per year, threatens to give the instruments for nothing and is introducing long-distance telephones to improve the service.

Partrick & Carter's House Goods Specialties.

Sample Board for Agents.

The Partrick & Carter Company of Philadelphia have prepared a very handsome Sample Board of some of their House Goods Specialties, designed especially for small dealers and those who do not as yet carry a stock of such supplies. Everything is connected and in complete working order for practical exhibition. The Board is made of hard wood with dealer's name and address in gilt letters. An advertisment in this issue shows an illustration of this new Sample Board, which will be boxed and shipped complete with battery on receipt of price.

Mather Company's Sales.

The Mather Electric Company of Manchester, Conn., report the sale through Messrs. H. B. Coho & Co., of the "Mail and Express" Building, New York City, of one 250-light and one 350-light Improved Mather Ring Type Dynamos for the new lighting plant of the Portland apartment house, Washington, D. C., Messrs. Coho & Co. having been awarded the contract for the entire plant, including McIntosh & Seymour engines, piping, fittings, etc.

MICANITE.

The latest specimens of the product of the Mica Insulator Company, New York, show the highest developments in their process yet achieved. The concern has been very prosperous, even during the past two years of general depression, and has found a regular and persistent increase of business. This is due, of course, to the fact that they make something which the people want. They draw special attention to the Micanite Plate, Cloth and Paper. The Plate, from which Commutator Segments, Rings, etc., are made, is of lighter color, almost transparent, showing a smaller proportion of cement than heretofore. This improvement has been attained by special machinery and greatly improved methods.

RECENT COMPANY ELECTIONS.

New York and New Jersey Telephone Company, New York. President, Charles F. Cutler; vice-president and general manager, W. D. Sargent; secretary, Joel C. Clark; treasurer, Henry S. Snow. Directors: C. F. Cutler, Alexander Cameron, M. F. Tyler, J. P. Davis, C. A. Nichols, Hugh Kinnard, W. D. Sargent, D. B. Powell, G. H. Prentiss, J. C. Clark, Felix Campbell and E. J. Hall.

Bennington and Woodford Construction Company, Bennington, Vt. President, H. W. Martin; vice-president, Dr. D. M. Gorton; treasurer, W. F. Keefe; secretary, C. H. Mason. Directors: W. J. Turck, Jr., C. W. Crispel, W. F. Keefe, John Robinson, H. W. Martin. The company's charter gives them the right to build railroads and erect telegraph and telephone lines.

Bennington and Woodford Electric Railway Company, Bennington, Vt. President, C. W. Crispel; vice-presipent, H. W. Martin; secretary, C. H. Mason; treasurer, W. F. Keefe. Directors: C. W. Crispel, W. F. Keefe, W. J. Turck, Rondout; Amos Aldrich, Woodford; H. W. Martin, Bennington.

Consolidated Telegraph and Electrical Subway Company, New York. Directors: William M. Wolverton, Robert M. Gallaway, Edward Lauterbach, Charles F. Cutler, Edward Hall, Edgar L. Ridgway, John H. Cahill, Edward E. Gedney and John Jameson.

Hudson River Telephone Company, Albany, N. Y. President, Gen. Selden E. Marvin; vice-president, James H. Manning; general manager, Henry E. Hawley; secretary and auditor, Walter B. Butler; treasurer, Jas. J. Fitzsimmons. Directors; James Bigler, Henry L. Storke, Selden E. Marvin, John E. Hudson, James H. Manning, Joseph P. Davis, C. Jay French, D. Cady Herrick, D. B. Parker.

Little Falls and Herkimer Street Railroad Company, Herkimer, N. Y. President, J. V. Quackenbush, of Mohawk; vice president, Charles Bailey, of Little Falls; secretary, Nelson J. Davis, of Utica; treasurer, Clinton Beckwith, of Herkimer; executive committee: William F. Lansing, of Little Falls, and Robert Earl, 2d, of Herkimer.

Cleveland Gas and Electric Fixture Company, Cleveland, Ohio. President, R. E. Gill; vice-president, Bernhard Schatzinger; treasurer, B. G. Tremaine; secretary, H. L. Taylor. The officers and L. Poplowsky constitute the board of directors.

Salt Lake and Ogden Gas and Electric Light Company, Salt Lake City, Utah. Directors: C. S. Hilton, W. S. McCornick, P. L. Williams, T. W. Ellerbeck and James A. Keaman.

INCORPORATIONS.

The Interurban Street Railway Company, Saginaw, Mich.—to build an electric road between Saginaw and Bay City, Mich. Directors: Frank E. Snow, John M. Nichol and W. A. Jackson, of Detroit, and Isaac Bearinger and W. J. Hart, of Saginaw.

The Marion Light, Heat and Power Company, Marion, Iowa—to make, buy, sell and deal in electric light, power, machinery, fixtures and appliances used for same. Capital stock, $50,000. Promoters: J. E. Bowker, C. C. Hodges, W. M. Hodges, Marion.

Certificates of incorporation are being prepared for the Baltimore, Westport and Annapolis Electric Railway and Tramway Company. The capital stock of the proposed road is $100,000. Among the incorporators are Henry Yewell Bready, A. C. F. Boehme, Jr., O. Parker Baker and others, all of Baltimore.

The Woodruff Place Light, Heat, Power and Water Supply Company, Woodruff Place, Ind. Capital stock, $10,000. Promoters: Jas. R. Carnahan, John M. Spann, J. F. Bent, Indianapolis.

The Citizens' Light, Heat and Power Company of Mahanoy Township, Shenandoah, Pa.—to supply light, heat and power. Capital stock, $10,000. Promoters: Jno. Riley, Harvey W. Wood, Jno. T. Lamorell, Philadelphia, Pa.

The People's Electric Light and Power Company, Calais, Me.—to furnish incandescent and arc electric light and power to the city of Calais. Capital stock, $50,000. Promoters: Martin Cone, Geo. S. Murchie, Ashley St. Clair, Calais.

The Ironton Electric Railway, Light and Power Company, Jersey City, N. J.—to erect, own and operate works for electric light, heat and power. Capital stock, $300,000. Promoters: Lucius C. Joyce, Plainfield, N. J.; Geo. L. Choarer, T. Channon Press, New York City.

The Faultless Gas Saver Company, San Francisco, Cal.—to purchase patent rights for gas, water and electrical machines, appliances, regulators and savers, to manufacture appliances for measuring, and contract for water, gas and electricity. Capital stock, $100,000. Promoters: E. J. Norris, A. K. Stevens, J. Kroaker, M. S. Fernburg, C. W. Nevine, San Francisco.

The Joplin and Galena Electric Railway Company, Webb City, Mo.—to build and operate street railways. Capital stock, $120,000. Promoters: Gahen Spencer, A. H. Waite, of Joplin, Mo.; H. H. Harding, Carthage, Mo.

The Canajoharie Electric Light and Power Company, Canajoharie, N. Y.—to manufacture electricity for Canajoharie and Palatine Bridge. Capital stock, $25,000. Directors: W. J. Arkell and Bartlett Arkell, of Canajoharie, and Austin L. McCrae, of Gouverneur.

The Brandenburg Under-Car Electric Railway Company, Chicago—to manufacture street car appliances. Capital stock, $5,000,000. Incorporators: George Brandenburg, George W. Van Zandt and William A. Youmans.

The Fishkill Electric Railway Company—to build and operate a street surface railroad from the village of Matteawan to the village of Fishkill, N. Y. Capital stock, $50,000. Directors: John T. Smith, E. K. Tompkins, Chas. H. Watson, John Place, W. Weston, B. L. Smith, of Fishkill-on-Hudson; S. K. Phillips, W. H. Southard, of Matteawan, and Wilbur H. Weston, of Newburg.

ELECTRICAL PATENT RECORD.

LETTERS PATENT ISSUED MARCH 12, 1895

ELECTRIC RAILROADS AND APPLIANCES.

535,345. Closed-Conduit Electric Railway. Edward M. Bentley, Boston, Mass. Original application filed Dec. 11, 1885. Divided and this application filed Feb. 25 1891.

535,398. Conduit Electric Railway. Daniel O'Flaherty, Kansas City, Mo., assignor to Ella A. O'Flaherty, same place. Filed March 31, 1894.

535,524. Clamp for Trolley-Wires. Warren W. Annable, Grand Rapids, Mich., assignor of one-half to Butterworth & Lowe, of Michigan. Filed Nov. 23, 1894.

535,679. System and Apparatus for Applying Brakes to Electric Cars. Charles E. Davis, Chicago, Ill., assignor by mesne assignments, to James Parmelee, New York, N. Y. Filed Dec. 29, 1893.

ELECTRIC LIGHTS AND APPLIANCES.

535,443. Electric-Lighting System. Joseph I. Conklin, Brooklyn, N. Y. Filed July 30, 1894.

535,589. Electric-Arc Lamp. John C. Knight, New York, N. Y. Filed March 2, 1894.

535,692 Carbon-Holder for Arc Lights. Adam W. France, Philadelphia, Pa., assignor of one-half to Arthur H. Jones, same place. Filed Nov. 10, 1894.

DYNAMO ELECTRIC MACHINERY.

535,488. Thermo-Electric Generator. Harry B. Cox, Hartford, Conn. Filed March 8, 1893. Renewed Aug. 14, 1894.

535,489. Thermo-Electric Generator. Harry B. Cox, Hartford, Conn. Filed March 8, 1893. Renewed Aug. 14, 1894.

535,490. Thermo-Electric Generator. Harry B. Cox, Hartford, Conn. Filed March 8, 1893. Renewed Aug. 14, 1894.

531,491. Indicating System for Thermo-Electric Generators. Harry B. Cox, Hartford, Conn. Filed Jan. 31, 1894. Renewed Feb. 13, 1895.

535,511. Electrical Controller. Elmer A. Sperry, Cleveland, Ohio, assignor to the Sperry Electric Railway Company of Ohio. Filed Nov. 11, 1893.

535,530. Starting Alternating Motor. Ossian Chytraeus, Pittsfield, Mass. Filed Dec. 4, 1894.

535,579. Armature-Conductor for Dynamo-Electric Machines. Henry Geisenhoner, Schenectady, and Christian Sandman, Niskayuna, N. Y. Filed Jan. 15, 1895.

535,796. Construction and Regulation of Dynamo-Electric Machines. Charles D. Haskins, Brooklyn, N. Y., assignor to the Western Electric Company, Chicago, Ill. Filed Aug. 6, 1894.

535,797. Regulation of Dynamo-Electric Machines. Chas. D. Haskins, Brooklyn, N. Y., assignor to the Western Electric Company, Chicago, Ill. Filed Aug. 6, 1894.

TELEPHONE AND TELEGRAPH APPARATUS.

535,540. Automatic Telephone-Switch. Newman H. Holland, Montreal, Canada. Filed Aug. 10, 1894.

535,615. Telephone. William W. Dean, St. Louis, Mo., assignor to the Bell Telephone Company of Missouri, same place. Filed Sept. 24, 1894.

535,745. Telephone-Exchange Apparatus. Charles Felix Gaston Marie Bigot de la Touanne, Paris, France. Filed Dec. 30, 1893.

535,806. Automatic Central Telephone-Switch Apparatus. Franz Nissl, Vienna, Austria-Hungary. Filed Feb. 17, 1894.

BATTERIES.

535,464. Battery. Henri N. F. Schaeffer, Manchester, N. H., assignor to Gilbert Brothers & Co., Boston, Mass. Filed Jan. 9, 1893. Renewed Jan. 31, 1895.

535,541. Method of Constructing Secondary Batteries. Arthur Hough, San Francisco, Cal. Original application filed Sept. 14, 1893. Divided and this application filed Dec. 14, 1893.

MISCELLANEOUS.

535,363. Electric Heating Apparatus. Mark W. Dewey, Syracuse, N. Y., assignor to the Dewey Electric Heating Company, same place. Filed March 12, 1894.

535,370. Electric Clock-Striking Mechanism. Fred L. Gregory, Chicago, Ill. Filed Jan. 30, 1894.

535,481. Electric Burglar-Alarm and House-Call. Henry L. Carpenter, Minneapolis, Minn. Filed April 16, 1894.

535,533. Electric Switch. Mark W. Dewey, Syracuse, N. Y. Filed Jan. 11, 1895.

535,660. Insulator. Warren J. Belcher, Hartford, Conn., assignor to the Billings & Spencer Company, same place. Filed Jan. 16, 1895.

535,703. Electric Cableway. Richard Lamb, New York, N. Y. Filed July 19, 1894.

RE-ISSUE.

11,478. Electrical Fixture. Luther Stieringer, New York, N. Y., assignor, by direct and mesne assignments, to George Maitland, Detroit, Mich. Filed Dec. 31, 1894. Original No. 259,235, dated June 6, 1882.

ELECTRICITY.

Vol. VIII. NEW YORK, MARCH 27, 1895. No. 11

ELECTRICITY

Published every Wednesday by the

ELECTRICITY NEWSPAPER CO.

B. E. GREENE, PRES'T. L. J. MONTGOMERY, SEC'Y.

PUBLICATION OFFICE:

6 Park Place - New York

EDITORS: { NELSON W. PERRY.
BURTON E. GREENE.
R. H. WILLOUGHBY.

SUBSCRIPTION RATES:

UNITED STATES,	$2.50
IN CLUBS OF FIVE OR MORE,	$2.00
FOREIGN COUNTRIES,	$4.50
SINGLE COPIES,	10 CENTS

ADVERTISING RATES:

As ELECTRICITY reaches all classes interested in electrical work, its value as an advertising medium can be readily appreciated. Rates will be sent on application.

Changes for advertisements should reach the office not later than the Saturday preceding the date of publication.

ENTERED AT THE N. Y. POST OFFICE AS MAIL MATTER OF THE SECOND-CLASS.

TRADE SUPPLIED BY
THE AMERICAN NEWS COMPANY,
THE WESTERN NEWS COMPANY,
And their Agencies in all Principal Cities.

EDITORIAL NOTES.

"ELECTRICITY'S" PLATFORM STANDS.

On August 31, 1892, ELECTRICITY outlined the policy upon which it would thereafter be conducted. The situation changes in detail only; the main features remain. Human motives and ambitions remain the same, whether expressed in one or another trade combination.

The question as to whether or not the electrical manufacturing industry shall be free to whomsoever has the capital, the knowledge and the legal and moral right to engage in it remains undecided.

The fundamental article of faith in the creed of the New York bankers who have been connected with the industry from the early eighties seems to be that they have *exclusive rights*, and that those who have come in since are trespassers, infringers and pirates who should be stamped out.

When one set of bankers, whose attempt at setting up a comprehensive monopoly in 1892 has been proved to be a flat failure, realize their impotence against the law of the world's progress, they yet refuse to read that law aright, cast about for others to join them, and outline new plans for the centralization of the business, still aiming at the annihilation of the rank and file.

ELECTRICITY will be here when all such schemes are buried beneath the crushing weight of individual effort and public sentiment.

Our platform to-day is just what it was in 1892, just what it will be in the next century. We reprint that platform from our issue of August 31, 1892:

"ELECTRICITY, under new ownership, will be conducted as an *entirely independent journal*, free to give its candid opinion on any and all matters of interest to the electrical fraternity. Our columns will be open at all times to those who have opinions to offer on such matters, whether they agree with us or not.

"We believe that these are the only correct lines upon which a journal, whether electrical or otherwise, can be conducted. We appeal for support to those who believe, as we do, in the fullest possible discussion of all matters of public interest; to those who believe, as we do, that the recent combination of electrical interests is foredoomed to failure in its main objects, and that its success, if possible, would work infinite injury to the development of the electrical industry of America.

"On this platform we stand, with the courage of our convictions and with no fears as to the result."

* * *

Consolidations.

Since the birth of the industry in America the business world has been upset with an almost systematic regularity by the announcement of trades, deals, absorptions, consolidations, or what not, that the parties to which, always in the earlier years, claimed were necessitated by the growth of the business and would result in benefit to the trade as a whole.

The history of these trades of all kinds is interesting, but at the same time not pleasant to consider. Time has shown that not one was ever made for a laudable purpose, and that with every new one the bedevilment of the whole business has been brought nearer to completion.

However humiliating it may be to admit it, we all must admit that the electrical manufacturing industry has been a veritable graveyard for the capital of the honest small investor. The reason is not hard to learn. The development of all the succeeding deals to their ultimate wreck has shown that the insiders feathered their nests without compunction at every step, while the small investor was being deceived and milked.

The overwhelming desire of those capitalists who have dictated the policy of the large companies from the beginning has been the manipulation of stocks; it has not been to establish a *manufacturing business* on honest and conservative lines. The large apparent profits made in the early days were spent in rascally schemes of one kind or another, and the backers relied for their profits on the gullibility of the public as to the enormous possibilities for riches in any commercial electrical scheme. A large part of the money was wasted in salaries to incompetent men of small caliber—men who might earn $2,500 in any old line business—drawing from $10,000 to $20,000 a year, not because of their ability to conduct an honest business, but for their willingness to negotiate crooked deals in country cities, or to *interest capital.*

The rights of the common stockholders have been ignored, the public has been worked persistently for 15 years. From the time when Edison Electric Light stock was sold at $4,000 to $5,000 a share, through all the successive "reorganizations" of the Edison interests up to 1892—a period taking in those wonderful financial transactions of the T.-H. Company and the raising of money by directors of the old United States Company on their own notes for the payment of dividends to keep up appearances as long as possible—the record is one to bring the blush of shame to the cheek of any man who has the best and honest interests of the trade at heart.

Many of the soundest thinkers in the business to-day are ready to express their opinion that the trade will never be upon a sound basis, offering a safe place for the investment of capital, until this entire element of traders and hucksters has been forced out. That they can ultimately survive in their battle against the fundamental laws of business is impossible, and Electricity is firm in the conviction that every new deal brings the inevitable so much nearer.

It is yet too early to state as a fact that a consolidation, a working arrangement, or any other arrangement, has been closed between the General Electric and Westinghouse interests. Negotiations are in progress—this much is not denied. That an understanding of some kind has been or will be reached may be stated as almost assured. Electricity will regret to chronicle the event when it happens. We do not see how it could be to the benefit of the trade as a whole, or even to the Westinghouse Company itself.

We assert unhesitatingly that we have fuller information at hand covering the history of the art and its commercial applications in this country than is possessed by any other newspaper in America, or by the bankers who are controlling the situation to-day. History does repeat itself, and the record of the trades of the eighties will be the record of all trades of to-day or of to-morrow.

The idea or theory of all combinations is one of hostility to the public interests and of injustice to all smaller competitors. In the early days of all Trusts, honeyed words are not soft enough to express the consideration felt by the managers for the public. Once established, or on the way to establishment, the cloven foot is disclosed; and thenceforth is never absent for one moment.

The comprehensive and detailed history of all the attempted combinations up to date which could be prepared in this office would leave no room for doubt in the minds of any thinking man that our deductions from known facts are entirely correct.

Electricity, with full knowledge of all that has been done, yet expresses the hope that the present proposed trade or arrangement will result in a failure to agree between the two large companies, and that the trade may be spared the disturbing effect of one, two or three years more of a policy of extermination whose mainspring would be a multiplicity of blackmailing patent suits against established businesses. Of the final end of any attempt to bottle up this business there is no doubt in our minds.

We hold that patents, as patents, should be respected, but that a conspiracy to form an unholy combination to make unjust use of such patents is not only unworthy of respect, but demands active opposition.

The American patent system is the best system in vogue in any civilized country. It is the dishonesty displayed in the procurement and handling of these patents, in addition to the perjury and concealment of truth on the part of so-called experts, the rottenness of the whole plan of expert testimony, which has brought the patent system itself into undeserved disrepute.

It is not possible now to prophesy except upon a hypothetical basis. On this basis Electricity gives its opinion unreservedly, based upon a thorough knowledge of the history of the past 15 years, that IF any combination of any character is officially admitted by the two large companies, the next twelve months will see the end of one of them. Not only this, but we believe we are safe in stating that the minute such trade is announced the companies will not be longer under separate management, but will be controlled absolutely by a committee of bankers who will dictate the policy and see that there is no conflict. It is not too much to fear that the plan which Mr. Coffin used in handling the Brush, Schuyler, Ft. Wayne and Excelsior companies would be adopted with some modifications.

We hope it will not occur. If it does, Electricity will be found battling as heretofore for the inherent rights of the independent element in the trade, backed by larger capital than any other paper in the field, prepared for a long fight, and with a knowledge how to fight which has been in evidence for nearly three years.

* * *

Preventing Armature Reaction. One of the most interesting and, in our opinion, most important papers that have come before the Institute in a long time was the one presented by Prof. Harris J. Ryan and Mr. Milton E. Thompson on Wednesday, March 20, in which was described a method for preventing armature reaction. While a paper of purely theoretical interest attracts due attention and is apt to give rise to some discussion, one which describes perfected methods calculated to supplant those in use is sure to be analyzed most critically. Prof. Ryan's paper, which was one of the latter class, proved no exception to the rule, and while there were few who were bold enough to come out strongly in advocacy of his methods, there were not a few who differed with him as to the necessity at this time of providing in any way by additional winding against armature reaction. The method chiefly relied upon up to this time to prevent sparking has been to make the fields relatively so strong that the cross-magnetization of the armature coils even at the highest load will not be sufficient to change materially the axis of commutation from the position it occupies at very light load. This, together with a proper proportioning of the poles, the shaping of the pole-horns and a proper adaptation of air-gap, as well as the use of carbon or other high resistance brushes, has enabled skilled designers to construct machines that are claimed to be practically sparkless throughout their whole range of load. This was in fact the basis of all the criticisms offered against the method described in the paper, and yet, notwithstanding the great perfection thus obtained, the commutator is still admitted to be the weak point in direct current machinery. In direct current generators the amount of copper that can be put on the armature is limited by practical considerations; the clearance or air gap reluctance must in one way or another be made large, which is a step in the wrong direction when efficiency is the ultimate end. It is a question of the choice between two evils, and with present methods *it is found* that the lesser evil is the increased reluctance of the magnetic circuit, introduced *purposely* at one point while at all other points every effort is made to reduce it by the use of *iron of high* permeability and ample section. The limitations thus placed upon the voltage *which* can be used in direct current machines have thrown them into the background where *long* transmissions are concerned, and again it becomes a question of choice between two evils. It is found that where high potentials are necessary it is better to put up with all the difficulties inherent in alternating currents than to use the more convenient direct currents and endure the sparking which inevitably results from attempting too high potentials.

It seems to us that there can be but one reply to the abstract question, "Is the prevention of armature reaction a desirable *attainment?*" and that reply is in the affirmative. Practically, however, we must consider the cost at which this is attained. We cannot afford to pay for this more than it is worth, and in all attempts that have heretofore been made the costs have been out of proportion to the results. On purely theoretical grounds the invention of Messrs. Ryan and Thompson seems to be open to at least two criticisms—1st, that the enlargement of the pole pieces rendered necessary by the balancing coils is not conducive to weight efficiency, and 2d, that the balancing coils themselves must interfere in a large measure with that freedom of ventilation so essential to efficient working. Practical use of the apparatus can alone settle to what an extent these seemingly objectionable features are controlling. On the other hand, the efficiency curve shown is a most remarkable one, and will overbalance many shortcomings in other directions. Thus a machine which at $\frac{1}{10}$ load has an efficiency of 70 per cent. and at $\frac{1}{3}$ load of 85 per cent. is one that must have some very serious counterbalancing disadvantages not to come into great popularity, especially under conditions of varying load such as are met with in street railway and central station practice.

We believe that Messrs. Ryan and Thompson have made a most important and valuable advance in dynamo and motor construction, and that if their machines can realize in actual conditions of practice the promises held out by test results, they will find a wide field of application.

Effects of Trolley Competition. We have commented at some length on the opposition of the New York, New Haven and Hartford Railroad to the granting of further franchises to electric systems paralleling the steam road and its branches in New England.

Our opinion has been expressed that the opposition was misplaced, because the best system will surely win ultimately.

The effects of the trolley roads upon the business of the N. Y., N. H. and Hartford Company are plainly shown in the arguments advanced before the Railroad Committee of the Connecticut Legislature by Judge John M. Hall, vice-president. The loss of business by his company due to trolley competition is given by him as follows, and we suppose his figures are approximately correct:

"Between Norwalk and Rowayton, a loss of 50 per cent. of the entire business. Between Bridgeport and Southport, a loss of 80 per cent. of all business. Between Bridgeport and Stratford, $35 per day. Between New Haven and Woodmont station, 50 per cent. of all business. Between New Haven and West Haven, 70 per cent. of all business. Between Wallingford and Meriden, 30 per cent. of all business. Between New Haven and Lake Saltonstall, 45 per cent. of all business. Between Meriden and Yalesville, about 90 per cent. of all business. Between Southington and Plantville, practically all the business. Between Unionville and Hartford, 40 per cent. of all business. Between Hartford and Glastonbury, 30 per cent. of all business. Between Derby, Ansonia and Birmingham, 90 per cent. of all business. Between Ansonia and Derby, $1,500 a year. Between Naugatuck and Waterbury, $300 a month. Between Union City and Waterbury, $170 per month. Between Waterbury and Naugatuck, 96 per cent. of all business. Between Winnipank and South Norwalk, 50 per cent. of all business. Between South Norwalk and Winnipank, 90 per cent. of all business. Between Norwalk and Royalton, 50 per cent. of all business. Between Danbury and Bethel, 75 per cent. of all business."

If these figures are anywhere near correct they prove that our argument is unassailable. They show that trolley lines between cities and villages are patronized vastly more than the established steam lines offering the best of steam service. This means, of course, that the people prefer to ride on the electric lines. Now, if the people *prefer* to ride in that way, and if the trolley lines, on an insignificant investment compared with that of the steam road for track and equipment, can draw 50 per cent. or more of the traffic, capital will seek the former as an investment, the people will *demand* the service, and the trolley lines will continue to be built.

Progress is the order of the day, and it cannot be stopped for long by even the New York, New Haven and Hartford Railway.

The best thing for the latter to do, under the circumstances, is to buy up the electric lines, put on more cars, and cultivate the popular desire to ride in clean cars, running frequently and stopping for the passenger anywhere along the line, instead of compelling him to go out of his way to a depot and wait, oftener than otherwise, for a train which is not on time.

For long-distance traffic steam will probably have its own way forever; but for interurban traffic at moderate distances the trolley has already won, and the victory cannot be nullified by any protest, however strong, from the directors of steam roads.

From the exquisite impudence of these Connecticut directors one would suppose that that State had guaranteed a perpetual profit to the company when she gave the latter its charter.

Away with such small notions. Let the trolley proceed on its onward march. The people want it and the people always win in the long run.

Under the Searchlight.

Views and Opinions on Timely Topics.

WHO CAN TELL THE TRUTH?

In 1892, only three days before the news of the G. E. consolidation was public property, Charles H. Coster told the best friend he had in this city at that time that no such deal was in contemplation and that it *could not* take place. This was some time after the final papers had been signed and Mr. Coster had been present in his official capacity.

It is also on record that Mr. Samuel Insull, then the active manager of the Edison interests, was not aware that a trade was in progress until the morning after the *final* meeting of bankers at Mr. Villard's house up the river.

It is further on record that after every detail had been perfected and there was nothing further to discuss, the various heads of departments and officers of the Edison Company were called together to discuss the PROPOSED CONSOLIDATION. Is history repeating itself?

* * *

The Sagacity of the "Electrical World."

When the *Electrical World* attempts criticism of a contemporary it invariably omits the name of the journal, fearing that by naming it it will thereby give it a little free advertising. In its issue for March 16 it refers to us in the following manner:

> A BRILLIANT DISCOVERY.
>
> An electrical contemporary informs its readers that according to the recent Bate Refrigerating decision, the Edison lamp patent expired on May 10, 1894, and, therefore, "This decision will also have the effect of throwing out of court those cases for infringement of the lamp patent brought by the General Electric Company since the date of May 10, 1894, and doubtless affect other litigation of the same character!"

Scarcely had the ink gotten dry when the editor of the *Electrical World* was thrown into confusion by the actual fulfilment of our prophecy which he attempted to ridicule. The daily papers of March 23 contain the following:

> Judge Lacombe, in the United States Circuit Court yesterday, issued an order dissolving temporary injunctions obtained by the Edison Electric Light Company against the United Electric Light and Power Company, the Sawyer-Man Company, the Mount Morris Electric Light Company and a number of individuals.
>
> The order was made because the patent, No. 223,898, obtained Jan. 27, 1880, had expired.

Doesn't everybody think Mr. P. H. Johnston would better retire to the familiar atmosphere of Baxter street and leave electrical matters severely alone?

* * *

The "Electrical Age" Got This Off and It Is Good, Too.

One of our contemporaries symbolizes itself by an owl, and proclaims the fact that "We Never Sleep." An owl is a nocturnal bird of prey, with a large head. Owls in all ages and countries have been regarded as of ill omen. Does the shoe fit? We do not think it is at all creditable for one to admit that he never sleeps. It implies a sore head and muddled brain, when both should be clear. The brain needs a rest. But, of course, if there is no brain, that is a different matter.

* * *

IN the early weeks of the G. E. Company Messrs. Villard, Coffin, Hastings, etc., etc., cautioned the writer of this paragraph against speaking of the new company as a consolidation. Amalgamation was the word they preferred to use then—implying an even trade on both sides. A little later it was claimed by the T.-H. people that the Edison Company was bankrupt at the time they came together. And a little later the world knew that both the Edison and T.-H. companies were hopelessly bankrupt at that time and that six months' more of fighting would have landed them both in the hands of receivers.

Nearly three years after the event, it is now known to every one that no permanent benefit was derived from putting two bad eggs into one omelet. And no matter what breed of fowl laid them, there can never be a good omelet made from any number of bad eggs.

* * *

WHEN Mayor Schieren of Brooklyn gets round to appointing his committees on investigation as to granting franchises, charters, etc, etc., he should not overlook the electrical transactions that have taken place in the City of Churches. We opine that some of these transactions would be found to have been of a decidedly spicy and novel character.

To WHOM now belongs the title "The Leading Independent Electrical Company of America"?

THE S. K. C. SYSTEM IN BROOKLN.

Exhibition in the Station of the Citizens' Illuminating Company.

On Friday evening, March 22d, an informal reception was given at the station of the Citizens' Electric Illuminating Company in Brooklyn, the guests being invited especially to see the S. K. C. two-phase system in operation.

A 60 K. W. generator supplied current, operating both a 3. H. P. and a 10 H. P. motor, in connection with a bank of 250 110 volt 16 C. P. incandescent lamps and twenty-eight arc lamps. The system worked to perfection, and nothing but favorable criticism was heard.

There was a large attendance of Brooklyn people, and a goodly delegation of New York men who had not been fortunate enough before to see the practical workings of the system.

The Citizens' Company, until recently, had been unable to make a feature of incandescent lighting owing to the patent situation. Now, however, it is freed from further annoyance, and will no doubt be a stronger factor than ever before in the local lighting situation in Brooklyn.

Their plant is equipped with three Wright engines aggregating 1,100 H. P., driving thirty-nine 45-light Thomson-Houston arc dynamos, with a total capacity of 1,755 arc lights. A new addition is equipped with two McIntosh & Seymour vertical triple expansion condensing engines of a capacity of 400 H. P. each, and twenty-eight Thomson-Houston 45-light dynamos. The steam plant is composed of nine Logan boilers with a capacity of 150 H. P. each, and six Cowles water tubular boilers of a maximum capacity of 250 H.P. each. The feed pumps and condensers are of the Worthington duplex type, and the feed-water heaters are of the Goubert manufacture.

The president of the company, Mr. Bernard Gallagher, and the superintendent, Mr. E. F. Peck, entertained the guests in a royal manner.

A METHOD FOR PREVENTING ARMATURE REACTION.[*]

BY HARRIS J. RYAN AND MILTON E. THOMPSON.

In the designing of continuous current dynamo machinery probably nothing has presented so much difficulty as the problem of avoiding the various evils resulting from the magnetic effects of the current that passes through the armature of the machine. Such magnetic effects are usually spoken of as armature reaction. These evils are at the present time well known and pretty well understood by the electrical fraternity in general, and the modern dynamo designer who is not thoroughly well posted on the subject would be wholly unable to design machinery capable of successful competition with some of the machines now on the market. The tendency of the currents that circulate in the armature coils is to produce a cross magnetism through the core at right angles to the natural field, resulting in a distortion to the natural field of the dynamo—a piling up of the magnetic lines under the trailing pole corners and a weakening of the field under the leading pole corners. This distortion, of course, increases with the current furnished by the machine, and if not specially provided against it may result in bringing the trailing pole corners to complete saturation and in completely reversing the field under the leading pole corners. While this distortion is no great evil in itself the resultant effects may be, and usually are, very serious evils. All distortion of the natural field of a dynamo is sure to be attended by a diminution of the field strength, resulting in a falling off of the E. M. F. produced by the dynamo, and if the distortion be very great no amount of compounding will cause such a dynamo to give constant potential. The most serious evil, however, arises from the fact that the weakening of the field at the leading pole corners results in a shifting forward of the neutral point or diameter of commutation of the dynamo. The amount of such shifting depends on the amount of distortion, and this in turn varies with the load on the machine. Consequently if the brushes are set on the normal neutral point when running light the machine will spark badly under load and it becomes necessary to keep shifting the position of the brushes to meet every variation in load. More than this, unless the pole tips or armature lugs are saturated, a point of loading is soon reached beyond which one finds no diameter of sparkless commutation, and the output of the machine has reached a maximum at this point, notwithstanding the fact that the load may be below that allowed by a safe heating limit. The facts, as before stated, are well understood by the more competent dynamo designers and receive the most careful consideration in the preparation of new designs. It must be confessed, however, that the principal part of the knowledge on this subject is the result of dearly bought experience and costly experiments, rather than of scientific study of the principles involved. Designers of dynamo machinery, with few exceptions, instead of aiming to prevent armature reaction, have endeavored to avoid its bad effects in various ways, and in some cases with fairly good results. The distorting effects of armature reaction become less in proportion as the reluctance of the air-gap and armature core teeth is increased, and the wiser designers of the present day, taking advantage of these facts, are producing some very creditable machines. Probably some of them still believe, as some of the very best authorities on the subject of dynamo machinery have confessed to believing until quite recently, that armature reaction is a necessary evil, and if it were possible to prevent it entirely the whole utility of the machine would disappear at the same time.

While making a thorough consideration of the subject of armature reaction some time since, one of the authors of this paper devised a means of entirely preventing armature reaction and resulting field distortion. On looking up the literature of the subject we found, mainly through the Patent Office records, that there were several workers in the field at a comparatively early date, viz., Prof. Elihu Thomson, Messrs. Andrews and Spencer, Mather, Forbes and possibly one or two others. The specifications given by Andrews and Spencer indicate clearly the technical side of this method for preventing armature reactions, while our part appears in the development of a plan for the practical application of the scheme technically outlined by them in 1886. This method consists in general in surrounding the armature with a stationary winding exactly similar in its magnetic effects to the armature winding, but directly opposed to it, and thus completely balancing all armature reaction. Fig. 1 is a diagram that shows the manner in which the coils are applied. Holes are provided immediately back of the pole surfaces, and through these holes are wound conductors which are placed in series with the armature. The number of ampere turns of the balancing coils crossing each pole face is equal to and opposite in direction to the number of ampere turns on the corresponding part of the armature.

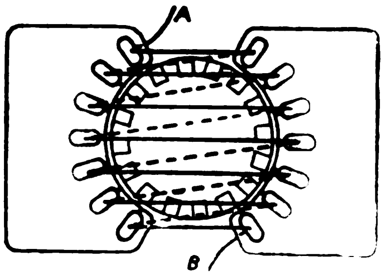

FIG. 1.

A small bipolar machine of about 2½ kilowatts capacity was designed, constructed and tested during the spring and summer of 1891, and the results obtained were very encouraging, demonstrating beyond doubt the correctness of one's understanding of the principles involved. Since that time some half-dozen or more multipolar machines of various sizes have been designed and constructed. All employ these balancing coils with various modifications of design and gave the following results.

Brief mention of these results has been made heretofore in the literature, while a complete report of the same is now made for the first time[*]. The following are the essential data of construction :

Field of cast-iron, two poles.	
Diameter of the armature core over all	6 in.
Length of armature core	6 in.
Number of teeth	64
Number of commutator bars	64
Armature turns per bar	3
Size of armature conductor, B. & S. G	12
Resistance of armature, ohms	.34
Speed, revs. per min	1,800
Output, amperes	25
Output, volts	100
Turns on field, 250 of No. 7 B. & S. G.	
Balancing turns, wound in six grooves per pole face, 16 turns per groove, or a total of 96 turns of No. 8 B. & S. G.	
Resistance of balancing coils, ohms	.24

There was no sparking at any point of the overloading ; the brushes were fixed on the no-load position, i. e., at the zero of field induction, and at all loads the currents in the sections were easily reversed without spark by the potential differences that were caused by the resistance of the carbon. There was no observable falling off of the induction through the armature under load when the balancing coils were used.

By operating as a dynamo or motor without the coil, extraordinarily powerful armature reactive effects are produced. It is seen that the brushes are in the presence of a reversed field that is quite as great as the normal no-load field of 3,000 lines per square centimeter, and moderate sparking with the carbon brushes occurred. Here the balancing coils bring out an interesting effect. One would expect that the effects of their over-balancing action would be *felt* more at lower excitations. In this experiment the induction at the advance pole tip or the position of the "commutation fringe" is almost doubled from the normal no-load value instead of being diminished as is ordinarily the case. It is appreciated that the effect of such behavior is to increase the strength of the commutating fringe at the leading pole tip in proportion to the load, thereby diminishing the range of change of the non-sparking point with metallic brushes, or enabling carbon brushes to be easily adjusted so that when in a fixed position there will be practically no sparking at all ranges of load.

The second machine that was built, and which made use of balancing coils, was a small one of the four-pole type with cast-iron field magnets. This machine was designed to have a capacity of 25 amperes at 80 volts, or 2 kilowatts when running at a speed of 1,200 revolutions. Fig. 16 is made from a photograph of the actual machine. The essential features of the design were as follows : Type of machine, 4 pole; field, cast-iron in two pieces. Armature, two circuit drum winding through 58 grooves; 5 No. 10 B. & S. G. wires in each groove; 29 commutator bars; grooves milled out, size $\frac{3}{8}$'' x $\frac{9}{64}$''; outside diameter of core 7½'', inside 3''; surface of completed armature wound with No. 14 B. & S. G. iron wire. Length of armature and poles, 6'' each. Effective length of iron in armature core, 5''. Magnetic leakage, 15 per cent. Field cores, 5'' x 2''. with rounded ends; area, 9.14 square inches. Mean length of field magnetic circuit, 12.5 inch. Magnetic density in armature core, 5,400 gausses; in air-gap, 4,900; in the armature teeth, 8,400; in the field cores, 6,800. Field winding, mean length of turn, 15 inches; requisite exciting M. M. F. for field circuit, 1,145 gilberts; for armature, 31.3 gilberts; for air-gap, 1,258 gilberts; or a total of 2,434 gilberts. Size of field wire, No. 18 B. & S. G. Number of holes for balancing coils, five in each pole-piece, even conductors per pole or 140 conductors total. Weight of complete machine, 400 pounds.

An examination of this data discloses the fact that no regard is had for the pernicious effects that are ordinarily met with in the use of so short an air-gap with a comparatively large number of armature ampere-turns. With the use of the balancing coils no such effects were observed; the machine performed precisely in accordance with the original estimate made in designing it, and exactly as theory shows that ordinary machines would perform if armature reaction were entirely absent.

During test the machine was belted directly to a ten H. P. Sprague motor, and ran at a speed varying from 1,500 to 1,650 rev. per min. The commutator was quite small for a four-pole machine; it had only 29 segments and was very poorly suited for the pressure of 100 volts at which it was tested. The machine was loaded down to 43 amperes at 100 volts, speed 1,650, and an exploration curve taken around the commutator. This curve clearly indicates the entire absence of field distortion. It was found that the machine would easily carry a load of 45 amperes continuously without overheating. After this curve was taken, the machine was loaded down as heavily as the driving belt would permit, and ran at a load of 80 amperes and 80 volts for about fifteen minutes. Under this load there was no appreciable difference from light load in the behavior of the commutator. The balancing coils were short-circuited for an instant while the machine was loaded to 40 amperes, and the vicious sparking that ensued showed that the dynamo could not be operated at this load without the balancing coils. Indeed the indications were, that it would have been fatal to the welfare of the commutator, and perhaps to the armature itself, to entirely cut-out the balancing coils when the machine was carrying this load. The balancing coils were then cut out and the dynamo gradually loaded down to test the performance without balancing coils. The brushes were shifted forward to prevent sparking as the neutral point changed, and the potential was kept up as much as possible by cutting out field rheostat. The maximum current reached was 37 amperes at 85 volts, with field rheostat all out, and speed 1,800 rev. per. min. At this speed and with this excitation the machine would have given 120 volts instead of 85 if the balancing coils had been used to prevent armature reaction. After a load of 37 amperes was reached, it was found impossible to raise the current by cutting down the external resistance, owing to the rapid fall of potential due to armature reaction. The capacity of this particular machine was about doubled by the addition of the balancing coils, and a comparison of the 37 amperes maximum with the 80 amperes which was by no means the highest possible current, shows that the overload capacity of this machine may be doubled by their use.

---

[*] "On a Method for Balancing Armature Reaction," *Sibley Journal of Engineering*, October, 1892, Vol. VII, p. 17. "Electromagnetism and the Construction of Dynamos," by Dugald C. Jackson, p. 172.

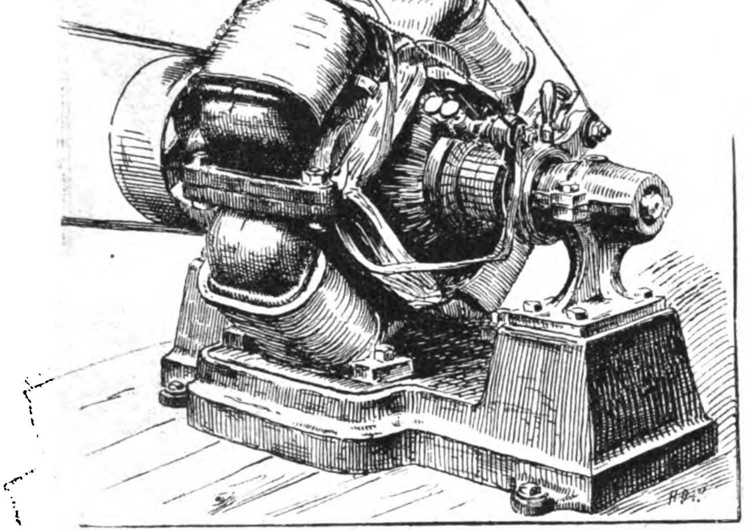

FIG. 2.

Two more machines of the same general design as the latter were built and tested. These machines were built with field magnets of mitis metal, and the pole-pieces and armature cores were one inch longer than the machine last described. The armature windings were different from each other and different from the cast-iron machine. One was wound with a two circuit winding and the other with a four circuit winding. Total weight of each machine was 450 pounds. Each machine, after running at 1,200 rev. per. min., carried a load of 85 amperes at 110 volts for two hours continuously, and was then loaded down to 100 amperes for a quarter of an hour. The performance of the machines confirmed in every particular the results previously obtained.

Two other machines of this same type were built—one of which was wound for a current of 10 amperes at 600 volts, and the other for a current of 550 amperes at 110 volts, or 60 kilowatts.

This type of machine was found to be expensive to construct, and owing to its exceeding compactness very hard to ventilate. The main plan in view when designing these machines was to lessen the total weight for a given output by taking advantage of the fact that when the balancing coils are used one may greatly increase the amount of copper on a given armature and still obtain the same satisfactory performance at the commutator.

Machine No. 7 was therefore built with a field of the ring type. This machine embodied a number of important improvements in details of construction, as will be hereafter noted. Fig. 3 shows a photograph of the machine from the pulley end, and Fig. 4 is a view from the commutator end. Fig. 5 is a view of the armature, which was wound with No. 6 wire cable. Both commutator and armature core were hollow, and the winding thoroughly ventilated. All armature coils were wound simultaneously and the winding was perfectly symmetrical. Fig. 6 is a view of the pole ring. This ring which carries the six balancing coils was made in halves, and the pole-pieces were joined together by small connecting lugs, as seen in the Figure, in order to make the casting continuous. This construction permits the field coils to be wound in a lathe, and to be easily removed from the fields at will. It is also a decided advantage to have the balancing coils and the pole-pieces through which they are wound separable from the rest of the field. The following are the more important details of the design of this machine: Capacity, 91 amperes at 110 volts or 10 kilowatts. Type of machine, six-pole, ring field of steel. Armatere winding of cable through grooves in core. Armature, ten inches in diameter outside by five inches inside; number of grooves, 61—six conductors per groove; grooves, $\frac{7}{32}$" wide by $1\frac{1}{4}$' deep; number of commutator bars, 122; total number of conductors, 366. Armature core and pole-pieces, five inches long. Mean distance between poles, $\frac{3}{4}$". Total magnetic flux, 1,800,000 webers. Maximum density in armature teeth, 14,400 gausses. Maximum radial density in armature core, 8,500. Mean air-gap density, 5,000. Maximum field density, 14,000. Length of air-gap, $\frac{1}{16}$"; M. M. F. for field, 642 gilberts; for air-gap, 1,600 gilberts; for armature, 99 gilberts; total M. M. F., 2,341 gilberts. Fields wound with No. 20 B. & S. G. wire. Armature, 366 conductors of No. 6 cable; five holes in each pole-piece for balancing coils. Balancing coils wound with copper ribbon. Compounding two series turns on each field coil.

Weight of field casting, actual	218	lbs.
" " armature core, shaft and spider	98	"
" " " and commutator complete	185	"
" " " copper	48	"
Weight of copper for balancing coils, actual	55	lbs.
" " field copper, actual	40	"
" " dynamo complete, including base bearings, brush holders, brushes and 14 x 9-inch pulley	865	"

This machine was completed and tested in October, 1894, and the results of test were as follows: Speed of dynamo, 1,065 rev. per. min. Voltage, 110. Current, 110 amperes. Time of run, one hour. Temperature of room, 71° F. Temperature of armature, 128° F. Temperature of field, 108° F. Rise of armature, 57° F. Rise of field, 37° F. Field resistance, 110 ohms. Field current, 100 amperes. Field energy, 110 watts. Armature resistance, .0512 ohms. Armature winding loss, 618 watts. Balancing coil resistance, .0202 ohms. Balancing coil loss, 242 watts. series resistance, .00955 ohms. Series loss, 115 watts. Core loss, friction, etc., obtained from energy absorbed as motor running light at full pressure, 450 watts. Total losses, 1,408 watts. Total output, 12,100 watts. Gross energy absorbed, 13,508 watts. Commercial efficiency, 88.7 per cent. This test was made after the machine had been running for several hours under various loads. On another occasion the machine ran one hour and twenty minutes under a load of 115 amperes at 105 volts with a rise of temperature of armature of 48° F. This load, it will be noted, is 25 per cent. above the rated full load. Yet there was an entire absence of armature reaction. The machine has also carried 135 amperes for one-quarter hour, and has several times been loaded down to 180 amperes for a few minutes at a time without damage.

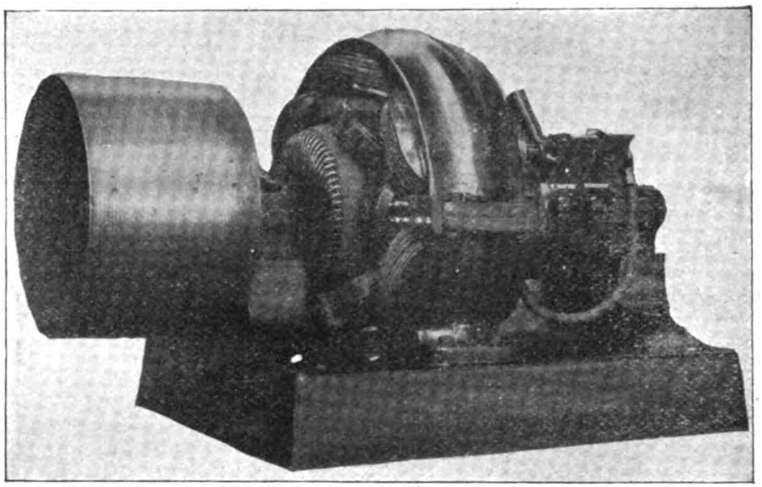

FIG. 3.

While the "balancing coils," as may have been seen from the foregoing results, entirely prevent field distortion and shifting of the neutral point, there is still something lacking for ideal commutation. In a constant potential dynamo, the following are the conditions for perfect and sparkless commutation: When a coil is short-circuited as it passes under a brush the current in the coil must fall to zero, reverse, and rise exactly to the original value in the opposite direction at the instant the short-circuited coil is opened by the passage of the tip of the brush from the commutator bar. To bring about this reversal properly, the short-circuited coil must move during short-circuit through a field whose strength is proportional to the armature current. In other words, the short-circuited coil should move in a neutral field when the machine is unloaded, and should move in a field of considerable strength when fully loaded. The field strength required for sparkless commutation under any particular load depends first on the resistance of the short-circuited coil; second, the self-induction of the short-circuited coil; and third, the duration of the short-circuit, which in turn depends on the width of brush and speed of the dynamo. Preferably the short-circuited coil should move in a uniformly distributed field. It is evident from this consideration that we do not get the conditions for perfectly sparkless commutation even where armature reaction is prevented if we attempt to commutate under pole corner. It is also evident that if armature reaction and field distortion *are* not prevented, we get just the opposite effect on our commutation from what we would wish—that is, our commutation field grows weaker as the current increases instead of growing stronger as it should. From this we may set it down as a settled fact that no dynamo of any considerable voltage and range of capacity which commutates under the leading pole corner and is not provided with some special spark preventing device or arrangement for preventing field distortion can be worked from no load to full load without sparking or without shifting the brushes. During their experimental work on balancing armature reaction, the writers devoted considerable time to the problem of sparkless commutation, and as a result have devised an improvement to be used in connection with balancing coils by means of which ideal commutation is attained. The device is simple, and accomplishes the desired end perfectly. It consists in bridging across the gap between the pole-pieces, attaching a commutation lug to the center of this bridge, and making this lug the center of the balancing coil, the latter being provided with a few extra turns. The arrangement is shown in Fig. 7, which represents a portion of the field circuit sectioned centrally in the plane of rotation. Referring to the Figure, *aa* and *bb* are two field coils wound round the pole necks C and D; G is the commutation lug which is attached to the middle of the lugs H I, which latter bridge across the gap between the pole-pieces E and F. The balancing coil (not shown) is wound through the holes K, L, M, N, O, P, with the commutation lug G at the center of the coil. The path for magnetism is indicated by the dotted lines. It will be noticed that a part of the magnetic lines are shunted across between the pole-pieces *e* and *f*, through the bridge lugs *h i*, and do not pass through the armature. Now when there is no current in the armature or balancing coils, it may be easily seen that the fall of magnetic potential from *e* to *f* is the same by either the path through the bridge lugs or through the armature, and that the commutation lug *g* attached to the middle of the bridge lugs must be at the same magnetic potential as the armature teeth opposite, for the latter are connected to the middle of the armature circuit. Therefore, under these conditions, which are practically what we have when the machine is running light, there will be no field between the surfaces R and S of the commutation lug and armature respectively. If then our brushes are set so that commutation takes place while the short-circuited coil is passing under the commutation lug, we have the correct conditions for sparkless commutation. When the machine is loaded, the excess of ampere-turns of the balancing coils over ampere-turns of the armature brings a magnetizing force to bear on the lug *g* in the direction indicated by the arrow. This tends to increase the magnetism through *h* and lessen it through *i*, but as *h* is normally saturated, there will be very little increase in its magnetism. There will, however, be a field established under the commutation lug, by the deflection of the lines from the bridge lug *i* through the commutation lug and armature, and it is evident that the stronger the current in the balancing coils the stronger will be the field under the commutation lug. We therefore again have the correct condition for sparkless commutation when the machine is loaded, provided our balancing coils are so proportioned as to give us a commutation field of proper strength. From this it will be seen that at all times the commutation field is proportional to the current, and that for all loads we have the requisite conditions for sparkless commutation without shifting the brushes.

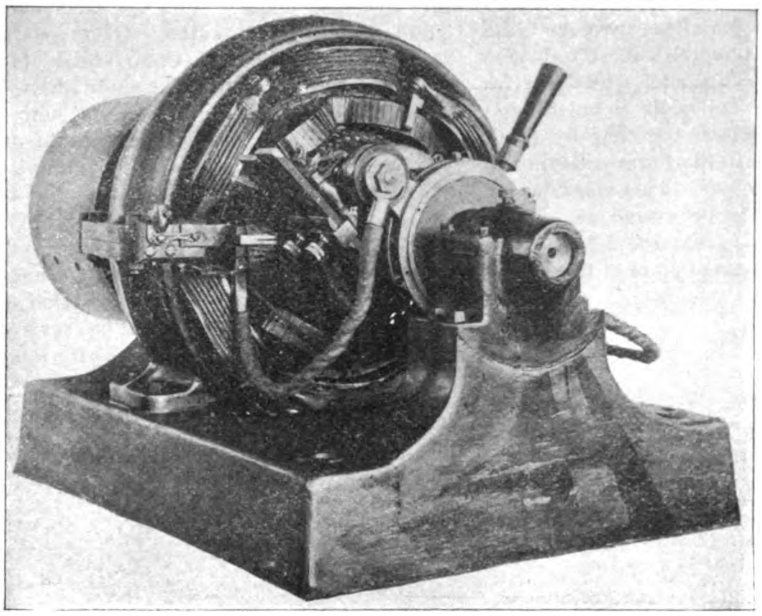

FIG. 4.

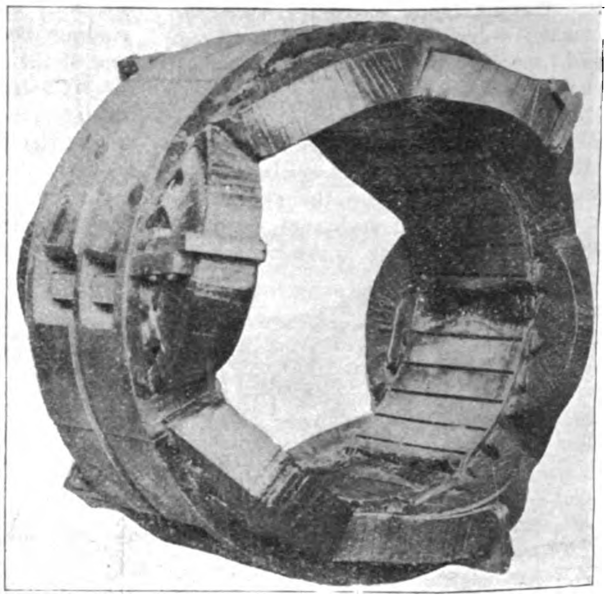

FIG. 6.

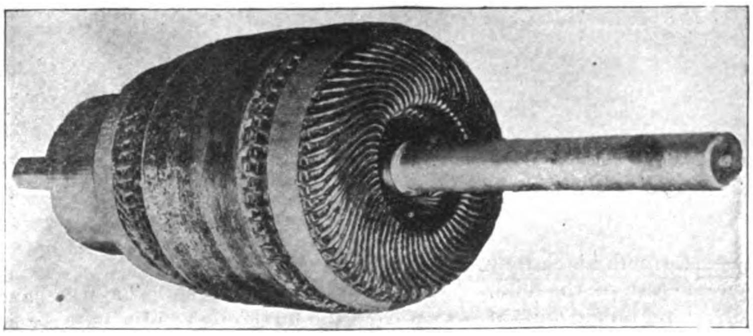

FIG. 5.

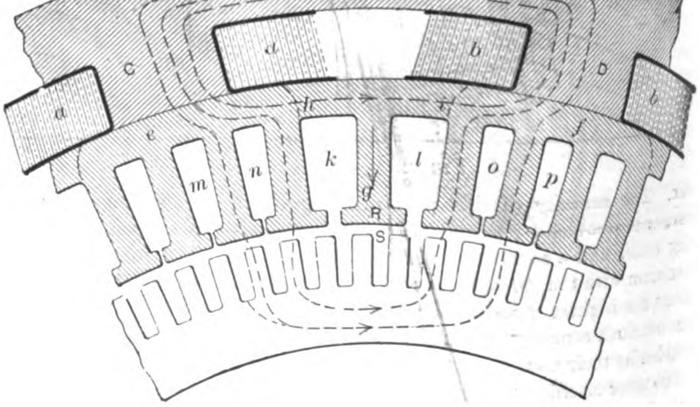

FIG. 7.

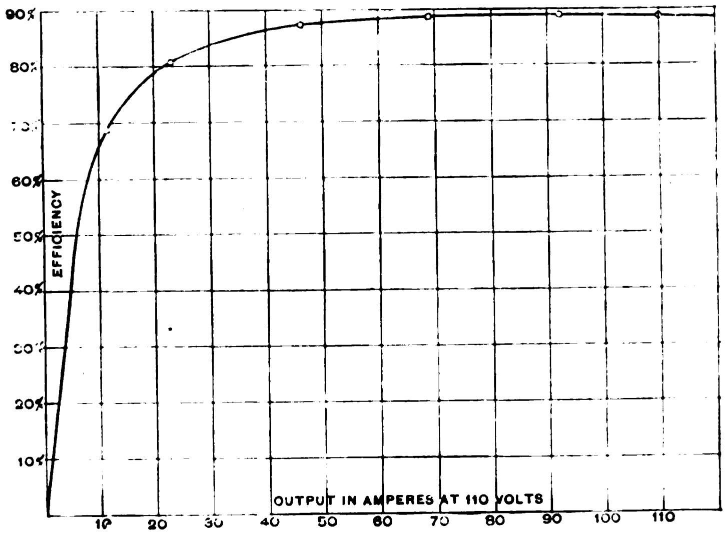
So much for the theory of this plan, and now comes the important question, "Will it work in practice?" We are able to answer without hesitation that such a machine performs as well in practice as in theory, and that actual tests show absolutely sparkless commutation from no load to 50 per cent. overload with fixed metallic brushes. More than this, practice confirms another theoretical advantage of this improvement which we have not yet touched upon. It will be noticed that the commutation field is obtained by the deflection of lines from bridge lug I and that the lines so deflected pass through the armature and consequently are added to the useful magnetic field. We might expect from this, and from the fact that since the brushes are midway between the poles there are no back ampere-turns, that the machines would compound somewhat without a regular compound winding. This theory was entirely sustained by actual trial. It was found under test that by slightly shifting the position of the brushes forward or backward it was possible to make a few of the armature turns act with or against the field winding at will, and this without any effect on the sparkless commutation, so long as the brushes were not moved beyond the limits of the commutation field. The result of this is that by simply shifting the brushes the compounding of the machine may be so changed that it can be adjusted at any point from 10 per cent. drop to 10 per cent. over compound, and this without interfering with the commutation in any way.

Thus by this simple contrivance we obtain sparkless commutation without shifting of brushes, and a compounding adjustable at will. It is not claimed that the broad idea of a commutation lug is new, but the success of such a contrivance depends altogether on the way in which it is applied. Unless the magnetic effects of the armature currents are taken care of properly, a commutation lug would prove worse than useless, and we would be likely to get an effect just the opposite of that desired. Thus it will be seen that the advantages which we have shown as resulting from the use of this system of commutation arise, not from the use of a commutation lug alone, but from its use in connection with coils for balancing armature reactions. Direct experiment has shown that this system of commutation will not give satisfactory results except when used in connection with balancing coils. Aside from the effect on commutation, however, balancing coils have some very important advantages to which we will briefly call attention. By their use the capacity of a machine of given size and weight may be greatly increased, and the resulting machine still be far better in quality and operate more satisfactorily than those of ordinary design. The reasons for drawing this conclusion are briefly these: Since the output of these machines is in no degree limited by armature reaction, it is possible to load the armature with as much copper as can be crowded onto it and to work this greatly increased amount of copper to its safe heating limit, the heating of the armature conductors being the only limit to the capacity of a given armature; and the core losses may be much less in a machine of this type since the magnetic densities in the core may be made as low as we choose, and this will permit the armature to be loaded with still more copper.



Efficiency Curve.

With the standard peripheral velocity of 3,000 feet it is easy to get an output of 20 to 30 watts per pound total weight of dynamo, and for large sizes of machines even still greater output per pound. With armature reaction balanced, there is no necessity for high reluctance in air-gap and teeth, and it is therefore made as low as possible for the whole magnetic circuit. The air-gap is reduced to what suffices for clearance, and the armature and field are worked at as low densities as is consistent with economy of iron. By this means from one-half to three-fourths, or even more, of the ampere-turns on the field may be saved with a corresponding saving in field copper and field energy. This and the reduced core losses reduce the fixed losses in the dynamo to a minimum, bringing them below what is possible with the ordinary construction, and the result is a very material change in the shape of the efficiency curve of the machine. Since the fixed losses are very small, the machines will have unusually high efficiency on light loads; the efficiency curves run up very sharply and bend off to a very uniform efficiency throughout the greater part of the range of load. This is a very decided advantage where machines are expected to work under considerable range of load, as they usually are both for lighting and power purposes. In designing machines it is also an easy matter to proportion materials according to their relative prices. Thus, with a design containing a given amount of copper we can increase the copper slightly and reduce the iron and steel, keeping the capacity of the machine the same, and thereby effect a saving in cost perhaps, or we may increase the iron and steel and reduce the copper to effect a similar saving. With ordinary designs such an adjustment as this would be out of the question, except at a sacrifice of valuable qualities of the machine, for the invariable rule is that the M. M. F. of the armature ampere-turns may never exceed the M. M. F. impressed by the field between the pole faces.

The value of sparkless commutation is almost beyond price. Commutation has long been recognized as the greatest bugbear of continuous current machinery. Whatever adds to the life of the commutator adds to the durability of the machine, and the entire prevention of sparking is therefore an important feature. To be able also to have the brushes permanently fixed is of decided value, and this when taken with sparkless commutation makes a dynamo self-attendant to a greater degree than usual. The extra cost of applying these improvements to a dynamo is far more than balanced by the saving effected in materials, and the writers believe that the application of these methods of design in dynamos would make a pronounced and important step towards the practical perfection of this class of machinery.

George C. Pyle, of Indianapolis, has invented an electric headlight for locomotives which he thinks will entirely eradicate the objections which have hitherto prevented the general adoption of electric headlights. His new engine for driving the dynamo is a compound steam turbine and capable of very high speed. It is exceedingly simple, compact and light, weighing only 200 lbs., and there is nothing to get out of order about it, nor is there anything to wear out except the bearings and they run in oil. The expansive force of the steam is used to its utmost limit. The dynamo and engine are cast together and the armature is mounted directly on the engine shaft, which runs at 2,000 revolutions per minute. The lamp used feeds the carbon in a novel manner, having no gears or clutches about it. A company will be organized at once to place the light on the market.

NOTES ON RECENT ELECTRICAL ENGINEERING DEVELOPMENTS IN FRANCE AND ENGLAND*—III.

Discussion.

Mr. Townsend Wolcott—I would like to ask Mr. Leonard if he can account for the difference in the efficiency of the Parsons and the Laval turbines. There seems to be, according to the figures given in the paper, a great deal of difference in favor of the Parsons. I was not aware that there was any such difference. In fact, I thought that if there was any difference the Laval was rather the better so far as coal consumption per horse-power was concerned.

Mr. Leonard—I do not think there is any difference, and if there is a difference I am inclined to think also that it is in favor of the Laval. The tests made by Profs. Kennedy and Ewing were upon larger sized units than the ones in case of the Laval. I fancy that it may be that the smaller size was influential.

Another point which may perhaps be a little confusing is this: that the consumption of steam quoted for the Laval steam turbine of twenty pounds of water per horse-power hour is per horse-power actually delivered, as you may say, in the generator armature. In other words, the friction of the bearing and the loss of the gearing is eliminated, and it is a horse-power actually delivered, available in producing electric energy—of course, the efficiency of the armature is one thing left to consider—whereas the figures I quoted for indicated horse-power are, of course, at the beginning before any of the friction is eliminated.

Mr. John W. Lieb, Jr.—The author of this interesting paper informs us in the first few lines that his observations were made during a trip through England and France. Later on we find that in making a comparison with central station practice in this country he has drawn his conclusions so as to cover in his comparison not only England and France, but the whole world, and in this generalization he has, I think, fallen into an error which should not pass unobserved. While there are no doubt many excellent central stations in England and France, it is generally admitted, I believe, that the best types of both the low-tension three-wire and the alternating current systems of distribution are not to be found in the countries visited by Mr. Leonard. The claims of preëminence for American stations of these types which the author has advanced can be shown to be not well founded if the comparison is extended, as it should be, so as to include other European countries where central station construction has been less hampered by local legislation. I would therefore call attention to several stations in European countries not visited by the author, which, had he found it possible to visit them, would have won his admiration and made his comparisons more just to European central station practice.

I would in the first place cite as types of the three-wire low tension central stations which the author did not visit the central stations at Berlin. The Berlin stations have a combined output inferior only to two or three stations in America. They supply with current a connected installation equivalent to about 95,000 amperes. The equipment of these stations—boilers, steam piping, engines, dynamos and electrical apparatus—would certainly not suffer by comparison with any of our best equipped and most recently constructed American stations. I am not in a position to quote any figures as to the economy of operation of the Berlin stations, having seen only one figure given as to the economy of generating. It is claimed that on the average throughout the year 220 watts are delivered to the customers' premises per pound of coal, which is certainly an excellent economic performance. Although Mr. Leonard did not visit either the Dusseldorf or Hanover stations, both of these should have been included in such a comparison as he has made. In the case of the Hanover station, it is claimed that on an average during 1893, 220 watts were generated and 180 watts delivered to the customer per pound of coal; Dusseldorf during the same period averaging 140 watts delivered per pound of coal. Neither of these stations would suffer by comparison with our best types of American low tension stations. From the table compiled by the National Electric Light Association, including a number of

---

* H. Ward Leonard's paper read at a meeting of the A. I. E. E, February 27.

American stations, it appears that the best 24 hours' record covered by the table gave 208 watts generated per pound of coal.

Coming to the alternate current stations which are included in the comparison, the author refers to conversion from 1,000 to 50 volts. As a matter of fact there are very few stations in England, France, or in Europe generally, transforming from 1,000 to 50 volts; the European standard for alternate current stations being 2.000 to 2.400 volts primary, transforming down to 100 to 110 volts secondary. Mr. Leonard has not included in his comparison with American statistics the Vienna alternate current station, which would certainly not suffer by comparison with any station in the world. I must admit a limited familiarity with the alternate current stations in this country, owing to the fact that I have been abroad a number of years, but I think I am safe in saying that there is not an alternate current station in this country which in excellence of equipment, perfection of distribution, regularity of service, or economy in operation, is the equal of the Vienna station of the Internationale Electricitats Gesellschaft. Among the other European stations which ought certainly to be included in such comparisons as these, I would mention the alternate stations at Cologne and Rome. Both of these stations are excellent examples of alternating current station construction and contain characteristic types of modern equipment.

Passing along the paper I notice that the author calls attention to the system of charge to the consumer for current used by Mr. Wright at Brighton. I would say at this time that this system of charging on the basis of what the author happily calls the "load factor of the consumer" was first developed by Prof. G. Colombo, of Milan, Italy, the general manager of the Italian Edison Company, and it is still the basis of charge for current delivered from the Milan Edison stations. This system was first adopted in 1887 or 1888, and has been in use ever since with entire satisfaction to the consumer. I do not know that a definite claim for precedence in the application of sliding scale of charge has been put forward, but I take this opportunity to mention it. According to the system of charging for current in use at Milan the consumer is at liberty to choose between two systems of payment, either on the basis, first, of a fixed charge of a certain sum, 30 francs ($5.75) per lamp installed per year, plus a charge of 3½ centimes (.67c.) per lamp hour as registered by the meter, or, second, a charge per lamp hour as registered by the meter on a sliding scale at a rate varying from a maximum of 7.7 centimes (1.5c.) per lamp hour to a minimum rate of 4.8 centimes (.96c.), depending upon the number of lamp hours used per month per lamp equivalent installed. This system covers fully and satisfactorily the question of a consumer's load factor, and gives the best consumer—that is, theone giving the company the greatest return per lamp installed—the benefit of the best basic rate.

Another interesting point referred to by the author of the paper is the question of the station load factor. In Mr. Crompton's inaugural address before the Institution of Electrical Engineers in London he presented a curve showing the load on all of the London stations combined on the day of greatest output of last year, December 19. The load factor on this day was shown to be 33 per cent. It may interest the members of the Institute to know that the load factor of the combined stations of the Edison Electric Illuminating Company of New York on the day of last year when the output was greatest (December 10) was 34½ per cent. The load factor of the lower district supplied by the company, in which is included a large motor load, is somewhat less than 34 per cent.; the load factor of the upper district, which has only a small motor load, being slightly greater. The total K.W. hours of output of the combined London stations on the date referred to was 96.240. The combined output of the Edison stations in New York City on December 10 was 60,633 K. W. hours. The maximum load carried at any one time was in the case of the combined London stations 11.600 K. W.; combined Edison stations in New York 7,354 K. W. The connected installation in the case of the combined Edison stations in New York was: incandescent lamps, 234.494; arc lamps 3.014; motors, 7.616 H. P.; or a total equivalent installed of 178.000 amperes. It may seem strange that the load factor of such a district as the lower district of New York City, in which the motor capacity connected (in K. W. equivalents) represents 42 per cent. of the total connected installation, is not greater than in the case of the upper district, where the motor load represents only 16 per cent. of the installation. It should be remembered, however, that the lower district is eminently a business and industrial locality, and that after 6 o'clock the load curve drops off very rapidly to a minimum, while in the upper district we have a business and residential locality where the day load is light, but the evening load keeps up well and falls off gradually.

The President—In a paper so varied as this, and covering so many different fields experts in which are present, unless a desire is expressed to the contrary, I shall limit the speakers to ten minutes.

Dr. Chas. E. Emery—The author of the paper has in a racy and attractive way brought to the attention of those present matters in which he has been interested and instructed abroad. For this pleasant duty, well performed, I am personally much obliged to Mr. Leonard.

Taking up my marginal notes in order, the paper on page 134 states that the Parsons steam turbine delivers one kilowatt for 28 pounds of feed water, and continues: "This is equivalent to about 15.7 pounds of water per indicated horse-power per hour." The difference is so great it would seem that these figures need revision.*

I have been interested in considering the possibilities of the Parsons and the Laval steam turbines. The high speed should permit the use of a small and comparatively cheap dynamo, and eventually the engines should not be as expensive as ordinary engines. Moreover, the very small space required is of importance in a large city. I have wondered why the turbines have not been introduced here. I made a special examination of the Laval steam turbine at the Columbian Exposition, and though I had a special invitation and wore a judge's badge I could not get the operator to put a load of more than three or four kilowatts on an engine rated at 15 H. P., the excuse being that there was water in the steam. The reported tests of this turbine are very satisfactory, but it is a question if it has yet been put in commercial form.

As to the question of the load factor, I think the critical point has not been referred to in the paper. It is a question more of the distribution of the load through the day than of the inequalities of local demands. It is considered unfortunate to take an elevator as an illustration, for, although it may take 15 to 20 kilowatts at times, and be shut off entirely for considerable intervals, the demand is distributed throughout the day and into apartment houses far into the night, and as it is very rare that the heavy pull required by each of a large number of elevators will come at the same moment, by the well understood law of averages, such elevators make a fairly uniform load. It is very much like the average in railroad work. When a few cars are running the fluctuations are very great, but as the number is increased the load, though still fluctuating, gives a large load factor during the time of operation. It seems to me that the use of elevators and of electric current for various household uses should be encouraged, because such uses are distributed through a large number of hours per day. The real cause of the low load factor is that so many consumers want light at the same time. The evident cure, if practicable, would be to charge a higher price during the rush hours. The method which would best appeal to consumers would be to reduce the price for current used during other than rush hours. The Wright plan mentioned in the paper (p. 140), with a proper scale of prices, would possibly accomplish these purposes, but the results would probably be better understood by consumers if expressed somewhat as above.

The description of the Heilmann electric locomotive and its operation is certainly very interesting and involves some important considerations. It is fair to say that I had not thought of this system respectfully until I read the paper. It did seem to be impossible, when there are steam engines and a steam boiler already on a locomotive, to install an electric plant in addition to a steam plant on a special car, and in that roundabout way make a locomotive which would in any respect be more efficient than the direct use of steam applied to driving wheels in the first place. A few facts and some very simple calculations show that the idea is not as ridiculous as it seems. It would be unreasonable to dispute the statement that the cost of power from an ordinary locomotive is double that of stationary engines of the best type. There are two reasons for this: one, the necessity of obtaining such an enormous power from a locomotive boiler which with the customary construction must be put in a certain place under limited conditions, the effect of all of which is to bring the evaporation down to 5 or at most 7 pounds instead of 8 or 9. The other is the difficulty of obtaining economy with the simple arrangement of valve gear which has been adopted and with such variable piston speeds as are necessary. If, therefore, the steam plant of the Heilmann locomotive can be operated for one-half the fuel or anywhere near that, this saving, not considering interest charges, will more than compensate for the losses incident to the generation and utilization of electric current, even if the 50 per cent. extra weight of the Heilmann locomotive be considered as to that extent reducing the weight of the train The question immediately arises, however, why not adapt the distinguishing features of the Heilmann steam plant to a steam locomotive? It is perfectly possible to mount a boiler of larger size on a platform and to make locomotive steam cylinders which will operate as economically as those of an engine mounted on a platform itself, even if we have to increase the size of the drivers to bring down the number of revolutions of the engine. Were this done, the locomotive would be as economical as the steam plant of the Heilmann locomotive and the intervening electric machinery would produce loss instead of gain. That is, when the progress that has been made in the construction of the Heilmann locomotive is analyzed along more general engineering lines, the improvement suggested is one in locomotives, and not specially in electric locomotives. Curiously enough the general features of the system have been already worked out for ordinary locomotives, but were so far ahead of the times that they have not been generally adopted. What was called the Farlie locomotive, built some years ago, had two boilers mounted on a platform supported on two trucks containing only driving wheels. The steam was introduced to the cylinders through ball and socket joints. The system operated well, all the weight was on the drivers, and I think some of the original engines are still at work in one of the South American States. The Mason Locomotive Works took up the system later, using a single boiler, and with one propelling truck containing drivers at one end and an ordinary truck at the other. This arrangement enabled short curves to run on suburban routes, but Mr. Forney, now present with us, showed that this could be done with a locomotive of the ordinary type, carrying its own tender on the frame, but supported by a truck, as evidenced in the locomotives on the elevated railroads, and the Mason system has not been extended. The success of the Heilmann system will then only show the desirability of reviving the Farlie system, perhaps using only a single boiler of large size.

At present, as Mr. Leonard suggests, it is well to encourage the development of the Heilmann system as a means of ascertaining the desirable details of a practical electrical locomotive, even if the steam machinery afterward be taken off and the current supplied by some modification of the trolley system.

Mr. Herbert Lloyd—The conclusions Mr. Leonard comes to, resulting from his inspection of a single battery plant in Paris, are, I think, a little unjust to accumulators.. His figure of $107 per kilowatt for three hours' discharge about conforms to the American practice, but the statement that a battery worked at this rate will not have an efficiency of over 60 per cent. is, I think, erroneous. All the large batteries installed in this country have been guaranteed at a much higher figure than 60; 75 is more common. In comparing the relative first cost of battery plant and direct power plant, Mr. Leonard gives a first cost for a direct plant of $50 per kilowatt of output as against $107 for a storage plant of the same output. I will quote the remarks of Mr. Edgar, of Boston, at the Cleveland Convention last week. Mr. Edgar says:

"A first-class steam plant costs $100 a horse-power; everything inside of the building. That is being done to-day. The battery costs us a little over $50 a horse-power to do the maximum work."

One hundred dollars a horse-power for direct plant means of course $133 per kilowatt, as against $107 for battery, taking Mr. Leonard's figures. I have had occasion within the past thirty days to get an estimate on a direct electric power plant, and the figure of $100 per horse-power is the result of my efforts.

Were the comparison made by Mr. Leonard

---

* This may be explained by using rather low efficiencies. Twenty-eight pounds per kilowatt equals 20.89 pounds per E. H. P., of which 15.7 is practically .75, which is the joint efficiency of the engine and dynamo and corresponds approximately to 88 per cent. for the engine and 90 per cent. for the dynamo, or vice versa.

between the first cost of the two systems correct, his later remarks as to the profitable application of a battery with a 40 per cent. load factor would have some weight, but with batteries costing less per kilowatt of output than a direct plant, that contention falls.

Next, as to the idea of installing small batteries in customers' houses, that is going back to the earliest methods adopted in exploiting storage batteries in this country. In Haverford, Pennsylvania, this was tried eight or nine years ago on a large scale, but the idea of dividing a battery up into a lot of little installations, distributed broadcast, is vastly less practical than the installing of one large plant in the central station, and if it would pay the customer to install a small battery, it would certainly pay the lighting company to install a large one, as the first cost would be proportionally less, and the care and cost of maintenance infinitely smaller.

Mr. Leonard's remark that "the consumers' maximum load will sometimes occur at the time of maximum load in the central station, and when this accumulated load is put upon the central station the kilowatts must be there to meet the demand," is one of the best arguments I have ever heard in favor of accumulators.

Mr. A. E. Kennelly—I think we are much indebted to Mr. Leonard for his interesting paper. A subject of this kind is always interesting, because, while proverbially comparisons are sometimes odious, practically they are also sometimes very pleasant, and by seeing what our neighbors are doing we can often gain some advantage for ourselves.

There are three points in this paper I would like to mention. The first is that mentioned on page 130, namely that this country has suffered by having the electrical industry in the control of large corporations, and then on page 132 Mr. Leonard goes on to state that dynamos and engines are better here than they are anywhere. I suppose Mr. Leonard would not say that lamps are worse here than they are anywhere else, or that motors are worse here than they are anywhere else. So that we are forced to the conclusion that the superiority abroad must lie in the system of distribution, because there is nothing left but the systems to account for it. I can scarcely imagine that it can be maintained that in the commercial application of distribution there is a superiority in European countries, because I think you have only to take up a map of England's electrical distribution systems, for example, to see that the question of systems is a very rife one, and that there is no apparent uniformity of opinion as to which system is the best to employ, even under any given conditions. Thus it is stated by Mr. Leonard that under the most unfavorable conditions he can possibly imagine an alternating system has been put in in the middle of the City of London. He also mentions that dynamos cost much less here than abroad, and this in a country of corporate interference. Is that not an argument in favor of the fact that under the influence of aggregated capital processes of manufacture may have been so perfected as to greatly reduce the cost of construction, and while no doubt the effect of large corporations is to limit and interfere in some directions with electrical applications, yet in this compensatory world the diminished price of electrical apparatus is an evidence of one beneficent effect of large corporations.

The second point is on page 139, where allusion is made to the cost of this storage battery as being capable of supplying 8,000 10 C. P. lamps for three hours, and costing about $30,000, meaning $107 per K. W. That is evidently based on an estimate of an inefficiency in the lamps of 3½ watts per candle. I would like to ask whether that 8,000 lamps is not the true estimate, and that 4½ and even 5 watts per candle would not be a much more fair basis to take, in which the cost would come to $75 or $83 per kilowatt.

The third point I want to draw attention to is one that Dr Emery has already mentioned, and I think that it deserves all the insistence that can be brought upon it, namely that on pages 141 and 142, of this load factor. When you sell light to customers they all practically enter into a conspiracy to throw the light on at the same time, just about dinner time, and you must have power in the station to supply it, but when you sell power to run intermittent 10 horse power motors, even though they each take 30 horse power at starting, by no possibility can the customers enter into any conspiracy to all start together, and all the figures based on such a conclusion with regard to electric elevator motors are greatly exaggerated in consequence, and the rates which should be charged for a kilowatt-hour based on elevator work are correspondingly exaggerated. As a matter of fact, I think it is well known that elevator load is objected to more on the score of the difficulty of maintaining regularity of pressure in the mains than it is on account of the small load factor.

Mr. Wm. Maver, Jr.—I should like to say that there is at least one electric light station in this country that transforms from 2,000 volts to 100 and to 50 volts, the converters being adjusted to either 100 or to 50 volts on the secondary. That is, I believe, the Manhattan Electric Light Company of this city. The change was made from 1,000 volts transforming to 50 in the secondaries over a year ago. Of course, however, they employ the two-wire system in the secondary. I should like to ask Mr. Leonard how the switching of the secondary circuit from the converter to the regular three-wire system in Brighton is performed. Others may be interested also in that. Also on page 134, whether the vulcanized rubber cables referred to are lead covered, or if not, in what way they are covered, if he knows; and also the manner in which the air is chemically dried before it is led into the ducts.

(*To be continued.*)

American Institute of Electrical Engineers.

At the regular meeting of Council, held March 20, the following associate members were elected:

Thomas D. Boyles, W. J. Davis, Jr., Chas. T. Mosman, Schenectady, N. Y.; John D. E. Duncan, Pittsfield, Mass.; William Esty, Urbana, Ill.; Joseph W. Frost, Rollen N. Larrabee, Mariano L. Mora, Alex. Stratton, New York City; W. L. Garrels, St. Louis, Mo.; Lucien H. Gilmore, Stanford University, Palo Alto, Cal.; James E. Grist, Price I. Patton, Chas. H. Stanton, Philadelphia, Pa.; Wm. J. Hiss, Jr., Bethlehem, Pa.; Henry C. Jones, Montgomery, Ala.; P. R. Middlemiss, Tulane University, New Orleans: Ralph D. Mershon, Pittsburg, Pa.; M. J. O'Sullivan, Baltimore, Md.; Thos. A.W. Shock, Sacramento, Cal.

The following associate members were transferred to membership:

William Henry Powell, Manchester, Conn.; Alonzo S Kimball, Worcester, Mass.; Edgar Woods Mix, Thomson-Houston International Electric Company, Paris, France.

The Council has canvassed the nominating papers received from the membership and prepared the following ticket:

For President—Dr. Louis Duncan, of Baltimore.

For Vice-Presidents—Dr. M. I. Pupin, of New York City; W. F. C. Hasson, of San Francisco, Cal.; Angus S. Hibbard, of Chicago.

For Managers—Carl Hering, of Philadelphia; Bion J. Arnold, of Chicago; Charles F. Scott, of Pittsburg; Dr. Cary T. Hutchinson, of New York City.

For Treasurer—George M. Phelps, of New York City.

Three vice-presidents and managers hold over by the rules as follows: Vice-presidents—Prof. W. A. Anthony, Prof. Francis R. Crocker and James Hamblet, of New York. Managers—Prof. Harris J. Ryan, of Ithaca, N. Y.; Chas. Hewitt, of Philadelphia; J. J. Carty and W. J. Hammer, of New York; A. E. Kennelly, of Philadelphia, and W. D. Weaver, Chas. S. Brailey and W. B. Vansize, of New York.

At the meeting of the Institute in the evening eighty members and guests were present.

Attix Tube and Wire.

At a meeting of the New York Board of Fire Underwriters held on the 20th inst., on the recommendation of the Committee on Electricity, the following resolution was adopted:

"*Resolved*, That the Superintendent be authorized, until further notice, to approve the use of the Attix tube and wire, when equal in quality and insulation to the samples submitted to this Board and tested, under the same conditions where tubing would be permitted; provided that there is no splicing or tapping of the wire, but that its introduction shall be in all cases by the loop system; that in new buildings when necessary to carry it between floor and plastering it shall be through holes bored in the beams, not less than two inches apart, a single conductor in each hole, out of the reach of nails; and in old buildings where necessary to carry it within the reach of nails it shall be protected by some device from perforation; and provided further that the wire and tube be carried intact into the cut-out boxes, and that in no case shall the outer covering be removed before introducing the core wire into the cut-out box."

Cape Town, South Africa, is to have a municipal electric street railway to cost $500,000.

The Buffalo-Niagara Transmission Scheme.

The New York *Tribune* is one of the very few daily papers in the country that seem to be able to grasp the situation and at the same time dare to express their opinion. In this respect at least i is ahead of all of the electrical papers in that they grasp the situation but don't dare to enlighten the public.

When we see the Baxter street sheet, the *Electrical World*, defending the propositions submitted to the city of Buffalo by the Niagara Power Company we wonder what advertising patronage it is laying for. Since there can be no advertising whichever position it takes, perhaps our contemporary has been subsidized. At any rate the editor of the *Electrical World* has gained the reputation of *thinking* that he knows on which side his bread is buttered. The *Tribune* for March 18, in speaking on the subject of the Niagara transmission, says:

> There would be four kinds of losses: (1) In transforming at the power house up to a high voltage, (2) on the line, (3) in transforming down at Buffalo, and (4) in distribution over street lines to consumers. These could not well amount to less than 20 or 30 per cent. altogether, and they might, perhaps, reach 50 or 60 per cent. But if, for example, they amounted to just one-half, the $18 rate at the generator shaft would mean $36 to the consumer, without adding anything either for interest on the cost of the transmission plant or for operating expenses. This, however, is probably an extravagant estimate. The prices actually given, by the way, are for a twenty-four-hour daily supply. Some establishments require power, however, for only ten or eleven hours. Whether it would pay to put in storage batteries to utilize the surplus is a question which their managers must naturally consider. Richard Hammond writes to the Buffalo *Courier* to say that steam power, on a scale of 1,000 horse-power for ten hours daily, can be generated in Buffalo, where coal is very cheap, for $21 per horse-power. The Power Company, however, denies this, and estimates the cost at $32, besides quoting various experts as estimating the cost on a twenty-four hour basis at between $45 and $60. In some other cities, where coal is more expensive, it is said to be from $60 to $75.
>
> If, after this discussion, Buffalo decides neither to buy on the terms offered nor to let the Power Company bring in its own lines and supply the market, more distant cities may possibly be deterred by her example from patronizing the Niagara concern.

General News.

What is Going on in the Electrical World.

Loveland, Col.—The council has granted an electric light franchise to J. S. Alexander.

Aitkin, Minn.—This village at the recent election voted to bond itself for an electric light plant.

St. Louis.—The bill authorizing the Jefferson Avenue Railroad Company to change its motive power to electricity has passed the city council.

Belleville, Mich.—An electric railway from Ann Arbor to Trenton via Ypsilanti and this place is being talked off at Ann Arbor and Ypsilanti.

La Crosse, Wis.—J. B. Caterbury has organized a company to build a street railway line in this city. Horses will be used at first but electricity later.

Middletown, Conn.—It is reported that the Schuyler factory in this city, which has been closed over a year, will shortly be opened by its original sponsors.

Des Moines, Iowa.—The executive council has been considering the question of lighting the State House with electricity, and will probably advertise for bids.

Marion, Ind.—Judge Woods has made an order confirming the sale of the Queen City Electric Railway to Warren T. McWhinney and Charles W. Halderman.

Doyleston, Pa.—Frank Worthington and others are making efforts to secure the $50,000 needed for building an electric road between Doylestown and Willow Grove.

Versailles, Ky.—The council passed an ordinance on the 15th inst. providing for the purchase and erection of an electric light plant to be owned and operated by the city.

Elgin, Ill.—The Carpentersville, Elgin and Aurora Railway Company has applied for a license to incorporate, the incorporators being directors of the Elgin City Railroad Company.

Peabody, Mass.—The special committee on enlarging the electric light plant have made a report, recommending extensive changes, alterations and additions at a cost of $16,000.

Taylor, Tex.—The plant of the Taylor Electric Light Company is to be sold at public sale on the second Tuesday in April to satisfy a judgment in favor of the Taylor National Bank.

Wallingford, Conn.—The borough of Wallingford has decided to apply to the General Assembly for an amendment to its charter which will permit it to start an electric light plant.

Ludington, Mich.—The late contractor having declined the council's offer of $65 for an all-night arc light service, there is a plan on foot to have the city put in its own electric light plant.

Bucyrus, O.—A company, backed by Eastern capitalists, has accepted the franchise granted by the county commissioners for an electric railway to Galion and will begin the work in a few days.

Stowe, Vt.—At a town meeting held here recently a resolution was passed granting $40,000 in 4 per cent. bonds towards building the proposed electric road between Stowe and Waterbury.

Laurel, Md.—The plant of the Laurel Electric Light, Power and Heat Company has been purchased by Messrs. Joseph Friedenwald and Miller, of Baltimore, the heaviest creditors, for $7,000.

Nyack, N. Y.—The board of trustees has granted a franchise for a trolley road in this town to the Nyack Traction Company, the only stipulation being that work must begin by the 1st of July.

Seattle, Wash.—The Union Electric Company has absorbed the old Seattle Gas and Electric Light Company, and the new concern will, it is said, be known as the Union Illuminating Company of Seattle.

Boston, Mass.—The Globe Electric Light Company has made arrangements to purchase the building formerly occupied by the Boston Clock Company, on the corner of Clifton and Shirley streets, Roxbury.

Kansas City, Mo.—Arrangements have been made to equip with electricity the line of the Kansas City and Independence Rapid Transit Railway Company between this city, Washington Park and Independence.

Ogdensburg, N. Y.—The Ogdensburg Electric Trolley Company has purchased a mill property in the suburbs for a site for a power-house. Included in the purchase is a water power capable of developing 350 H. P.

Trenton, N. J.—A bill has been introduced in the Senate making it a misdemeanor, punishable by a fine of $500 or six months' imprisonment, to tap the wires of electric light or power companies or cheat the companies' meters.

Elwood, Ind.—An electric railway is to be built this spring from Elwood to Anderson via Frankton. Another line will be built the coming summer from here to Independence, connecting with the line from there to Marion.

Benton Harbor, Mich.—Peter English, who established the Benton Harbor waterworks has applied for an electric lighting and power franchise for this city, the power to be furnished by damming the Paw Paw river one mile above town.

Omaha, Neb.—The proposition to construct an electric road from this city to Fremont is received with favor by the property owners along the line. Col. J. H. Pratt and Frank Hibbard, of Irvington, are the chief promoters of the project.

Washington, D. C.—It has been decided to open stock books at once for the proposed Washington and Marlboro' electric railroad. W. A. Melay is president of the company, C. E. Coffin, R. V. Hall, J. T. Perkins and J. V. Belt are directors.

Ottawa, Ill.—The city council has notified the General Electric Company, owner of the Ottawa Electric Railway, that unless it operate all of its lines in this city on or before April 1 its franchise granted in 1889 will be forfeited at the first meeting in April.

Bloomington, Ill.—The power-house of the Bloomington Electric Light and Power Company was totally destroyed by fire on the night of the 18th. The loss is $50,000; insurance about one half. The building had just been equipped with new electric and engine plants.

Chattanooga, Tenn.—An equitable distribution of costs and liabilities has been agreed upon by the three classes of bondholders of the Union Railway and there is nothing now to prevent the sale of the road. All debts for running expenses and all damage suits will be shouldered by the Chattanooga Union Railway Company.

Norwich, Conn.—At a city meeting held here recently a resolution was adopted calling for an amendment of the city charter so as to enable the city to establish and maintain plants for the manufacture and distribution of gas or electricity, or both, for municipal use or for both municipal use and the use of the inhabitants of the city.

Baraboo, Wis.—There is every probability of a franchise being granted for the electric road between Kilbourn City and Devil's Lake. The ordinance has received its first reading. The promoters are Henry L. Desanges, Hoboken, N. J.; D. Harvey, Jr., Newark, N. J.; E. N. Marsh, J. B. Donovan and Dr. G. S. Cramer, Baraboo.

New York.—The strike of the electrical workers has ended. Through the mediation of Bishop Potter and others an amicable agreement was arrived at, the point conceded by the Contractors' Association to the men being an eight hours' workday from the 1st of May instead of the 15th of the same month as specified in the contractors' ultimatum.

Orange, N. J.—The South Orange township committee has granted, after several months' discussion, a franchise for a trolley road on Springfield avenue to the New York and Philadelphia Traction Company, thus virtually completing the last connecting link of the surveyed route for a trolley road between New York and Philadelphia.

Brooklyn, N. Y.—The Long Island Traction Company, lessee of the Brooklyn Heights Trolley Company, has passed into the hands of a receiver. Horace J. Morse, of the firm of A. M. Kidder & Co., bankers, New York, has been appointed receiver by the United States Circuit Court of Virginia, in which State the Traction Company was organized.

Brockton, Mass.—The Economic Electric Light Company, which formerly manufactured incandescent electric lamps in this city, and which was driven out of business by prosecutions for infringements of patents, is likely to resume business again, the recent decision of the courts having established the fact that their business is not an infringement.

Greensboro, N. C.—Bids will be received at the office of A. M. Scales, city clerk, until the 26th of April, for the lighting of the city of Greensboro with elctric lights of 1,200 C. P. each. The bids will be on the basis of a contract for three, five and ten years, and for fifty-eight lights, stating also price of each additional light. The board of aldermen reserves the right to reject any and all bids.

Ellicott City, Md.—A mortgage deed of trust from the Edmondson Avenue, Catonsville and Ellicott City Electric Railway Company to the Maryland Trust Company for $500,000 has been placed on record in this city. Bonds of $1,000 each are to be issued and the proceeds will be applied to the building and equipment of the railway company's road, which is to be thirteen miles in length.

Shamokin, Pa.—The Enterprise Coal Company is now fitting up its mine with an entire electric plant, and will after May 1 haul its coal along the gangways and illuminate the mine with electric power. This improvement, when completed, will do away with about thirty head of mules now used in the slope, and will increase the capacity of the colliery fully 50 per cent.

Milwaukee, Wis.—The board of public works considered the bids for putting in an electric light plant at the new city hall too high and will readvertise. The bids received were: Western Electric Company, $33,000, $36,718 and $40,550; General Electric Company, $39,687, $45,080 and $38,262; E. G. Bruckman, $39,856. Four thousand eight hundred and forty-one electric lights are to be lighted by the plant.

Halifax, N. S.—A bill to incorporate a new electric tramway company for this city is in the hands of a committee of the Nova Scotia Legislature. The new company is to be known as the City Electric Transit Company, and among those interested are John Quincy Adams Wentworth, of Boston; Robert C. Geer, of New York; Ephraim Hopkins, of West Chester, Pa.; James M. Pendleton and Charles Perry, of Westerly, R. I.

Lancaster, Pa.—Recently petitions were presented to court asking for the dissolution of the charters of several electric railway companies, the Lancaster and Lititz, Lancaster and Manheim, Lancaster and Strasburg and Lancaster and Middletown and Conestoga Valley. The reason given for asking for dissolution was that other companies had either built lines or it was not deemed advisable to build. The court issued a decree dissolving the charters.

Shelburne Falls, Mass.—The syndicate which recently bought the water power near Hoosac tunnel is rapidly pushing plans for the installation of a gigantic electric power station. If the petition for a charter now before the Legislature is acted upon favorably, as it is confidently expected it will be, the transmission of electric power and light to North Adams and the villages in the Deerfield Valley will be an accomplished fact before the end of 1895. There is about 1,000 horse-power immediately available.

Patchogue, N. Y.—The Port Jefferson and Patchogue Traction Company proposes to build, equip and operate a single track road from the dock at Port Jefferson through the main part of the village to Port Jefferson depot, then through Selden, crossing the Long Island Railroad west of Medford; then passing through Patchogue, reaching the great South Bay by way of Ocean avenue. The capital stock is $150,000. F. M. Wilson, O. T. Fanning and M. L. Chambers have been authorized to solicit subscriptions to the stock.

Harrisburg, Pa.—A bill introduced in the House permitting street railways to carry freight is warmly opposed by the friends of the steam lines, but the country members are red hot for it and it will probably pass.—Among the bills reported to the House from committee was the Senate bill authorizing traction or motor companies to enter into contract with each other to sell, lease and operate their respective franchises; also the Gould bill providing for the issuing of bonds equal to the amount of their capital by traction companies.

Toledo, O.—A new electric railway project has just been announced here. The proposed line is to run from Toledo to Sylvania, thence westward through the northern part of Fulton and Williams County, making it one of the longest of its kind in the United States. Instead of using the public highway it has secured over 45 miles of right of way upon private property. This is sufficient to take the road as far as Fayette, and such towns as Metamora, Lyons and Sylvania will be touched. George W. Acker, of Toledo, is at the head of the enterprise.

Chicago.—Two important mortgages have been placed on record here recently, both running to the Illinois Trust and Savings Bank, and aggregating $3,000,000. Of these two instruments one by the Chicago Electric Transit Company is for $2,000,000, for twenty years at 6 per cent., the other is by the Chicago Electric Railway Company for $1,000,000, for twenty years at 6 per cent. Both mortgages are given to secure a like issue of bonds, to be issued as required. They cover all the property and franchises of the grantor companies and are for equipment of electric lines and extensions of the North and West Chicago street car companies.

Philadelphia.—Proposals will be received at the County Prison until the 29th inst. at noon for incandescent and arc electric light plants, boilers, telephones, electric bells, burglar alarms, etc., for the new county prison in the 35th Ward of this city. Plans and specifications can be seen and all information obtained at the office of Wilson Bros & Co., engineers and architects, Drexel Building, Philadelphia.—The Electric Traction Company has completed the laying of six cables under the Schuylkill River at the South street bridge. They will carry power to lines of the Lombard and South streets division in West Philadelphia.

Baltimore, Md.—The Baltimore Traction Company is arranging for the introduction of palace cars for "trolley" parties during the summer, and are now corresponding with the builders for their construction. It is likely these cars will be run to the Arlington and Gwynn Oak sections, and will be leased to parties for the evening. Arrangements will also be made to serve luncheon on board the cars and music will also be furnished.—The contract for the cable and apparatus for the underground police telegraph and fire alarm systems has been awarded to the Western Electric Company of Chicago and New York. The contract price is $36,779.85.

Norwalk, Conn.—The Consolidated Railroad Company is said to be formulating plans to purchase several trolley railroads along its lines in Connecticut, including the Bridgeport Traction, the Norwalk Tramway, the Westport and Saugatuck Horse Railroad Company, the Westport and Southport Tramway Company, and such other street railroads along its lines the control of which will best serve Consolidated interests. The Consolidated, it is said, has become convinced that the extension of electric roads under old charters and under new ones, for which so many petitions have been presented to the Legislature, will parallel its lines to such an extent as to affect its income from short-distance traffic.

Springfield, O.—A. S. Krotz, electrician and chief engineer of the Springfield Electric Railway, has invented a gun with which he hopes to revolutionize modern armaments. The weapon he is experimenting with is a brass tube 5 feet long and 2½ inches diameter, with a smooth half-inch bore. The barrel is fixed to a wooden stock and an electrical current is applied directly to the projectile. There is no cartridge, powder, dynamite, smoke or noise. The advantages of the gun are that it may be made very light weight, that it cannot explode, that it is economic in expense of operation and that the limit of the number of balls it will throw within a given time is the number of balls that can be got within its breach consecutively in a given time.

Noblesville, Ind.—Experiments in carbon manufacture at the American Carbon Works here are said to promise a revolution in the manufacture of carbons for use in electric lighting. The process employed is a discovery of electricians connected with the Marks Electric Company of New York, who say that after five years' hard study they have virtually completed an invention for the prolongation of the life of a carbon. They do not hope to do this by changing the material from which the common copper-tipped carbon is made, but by bringing another and an entirely new method into use. Instead of the tips meeting and producing light on the streets in the open air, surrounded by a globe, open at both the top and bottom, the scheme now on foot is to have a perfectly air tight chamber, from which the light is emitted. This, the inventors claim, will enable carbons that now burn from eight to ten hours to last from seventy to ninety hours.

Telephone and Telegraph.

The Bell Telephone Company has nearly completed the installation of a telephone system in Tallahassee, Fla., and expects to be ready for business by the first week of April.

The dummy telephone has been of practical service in many country towns in ridding telephone subscribers of dead-beats.

The board of supervisors of Clay County, Ill., have granted the right to the Clay County Telephone Company, whose headquarters are at Clay City, to erect and operate a telephone system.

The Baldwin Bros. Co., bankers and brokers, of Boston, has purchased all the property of the New England Printing Telegraph Company.

The Middleburg and Oak Hill Telephone Company has been formed for the purpose of operating a line of telephones from Middleburg to Franklinton, to Livingstonville, to Hawverville, to Preston Hollow, to Oak Hill, to Durham, these places being in the counties of Schoharie, Albany and Greene, N. Y. Directors: Elias W. Dutton, A. B. Brayman and W. J. Chase, of Livingstonville; William Earles, George Graham and Absalom Graham, of Franklinton; A. S. Coons, George F. White and George M. Hallenbeck, of Preston Hollow; Emerson Ford, of Oak Hill, and Wellington E. Bassler, of Millersburg.

Representative Cody's bill, now before the committee on corporations of the Illinois House, proposes to regulate telephone charges in the State of Illinois and to empower certain State officers to revise and regulate the same. The leading provisions of the bill are similar to those of the bill now before the New York Legislature.

The Central Telephone Company is to have a competitor in New Castle, Pa. A new company is about to be formed there, and already over 100 signatures have been obtained of proposed customers; its rates are put at just half those of the Central Company.

Wisconsin Telephone Company officials are looking over the ground preparatory to building a metallic circuit line direct from Watertown to Chicago by way of Elkhorn, Williams Bay, Lake Geneva and Genoa Junction.

A bill has been introduced in the Illinois Legislature requiring telegraph companies to make a report to the Auditor of Public Accounts and fixing the assessment of such companies at the rate of 80 cents a mile for each separate wire.

The central office of the Southern New England Telephone Company has been removed from Essex to Saybrook, Conn.

The New England Telephone and Telegraph Company is getting ready for a large amount of new construction work during the coming summer. Among other things it is planning for a rebuilding of its trunk line from Keene, N. H., to St. Johnsbury, Vt., with copper metallic circuits. It will also rebuild, in the same way, its line from Rutland, Vt., to Burlington, Vt., thereby giving it a first-class metallic circuit line through from St. Albans, Vt., to Boston. It will, still further, put in the same kind of service between Portland, Me., and the White Mountain section, giving all the summer resorts there the best kind of lines. Down in Maine a copper metallic circuit line is to be built from Cherryfield to Machias, and a large amount of this work is also to be done in other sections.

The Franklin Telephone Company is canvassing for subscribers to establish a line between Englewood and Hackensack, N. J., and proposes an annual rental of $25 for each telephone. The present rate is between $60 and $100.

George W. Scheuing and associates have been granted the right to erect, maintain and operate a telephone exchange in Tallahassee, Fla.

The Southwestern Telephone Company of Martinsville, Ind., has been incorporated with a capital stock of $5,000. The company was organized for the purpose of operating a telephone system in the counties of the southwestern portion of the State from Marion to the Ohio river. The directors are Clark S. Crary, Sarah P. Crary and Charles W. Barkhurst.

A move is being made for the establishment of a telephone exchange to give service to Pierre, East Pierre and Fort Pierre, S. D.

The Phœnix Telephone Company has been organized in Indianapolis for local service, with a capital stock of $200,000. The principal stockholders are R. K. Syfers, Rollin H. McCrea, C. F. Smith, George Webster, Benjamin Webb, Charles McCreary, A. B. Gates, George W. Stout and William N. Gates. The list of subscribers already obtained, it is said, numbers 2,000.

The Bell Telephone Company is about to erect a long-distance telephone line from Griffin to Columbus, Ga., via Warm Springs, Greenville, Hamilton and Chipley.

At a recent meeting of the stockholders of the Le Sueur Center and Montgomery Telephone Company at Montgomery, Minn., it was decided to build the line at once. Officers were elected as follows: Charles C. Kolars, Le Sueur Center, president; J. R. Stratton, Montgomery, secretary; Charles L. Mark, Montgomery, treasurer.

The hearings on the Telephone bill at Albany are not yet closed. Another adjournment has been taken to the 12th of April. One of the strongest advocates of the bill considers this delay as tantamount to the defeat of the bill.

The highest special license assessment in Richmond, Va., is that of $800 against the Bell Telephone Company. The Western Union Telegraph Company is down for $500 and the Postal for $200.

The telephone war between the Central Union and Pana companies at Elwood, Ind., promises to bring free service. The Central Union has cut rates to $1 per month for business houses and 66 cents for residences.

J. E. Keelyn, president of the Western Telephone Construction Company of Chicago, has lately been in Pittsburg, Pa., and has taken steps to organize a new telephone company in that city.

The Germans are taking the lead in Europe in the erection of long-distance telephone lines. They have just put up four silicon bronze telephone wires between Berlin and Vienna, a distance of 409 miles. There is a longer line—496 miles—between Berlin and Konigsberg, and the German administration expects to build a 682-mile line from Bodenbach to Trieste, while it has also been experimenting between Berlin and Trieste, a distance longer than any, namely, 725 miles.

Police Commissioner Andrews made a thorough inspection of the New York Police Headquarters a few days ago, and among other things criticised the telegraph system, which he said was primitive and wholly inadequate to the needs of the department. He said that it was imperatively necessary that the department be equipped without further delay with a complete signal system. "A signal box," he said, "should be placed on the post of every policeman, thus enabling him to communicate at a moment's notice with the station houses."

Alfred L. Tetu, late manager of the Chicago Telephone Company, has taken a place with the Central Union Telephone Company at Chicago and will have control of the superintendents of the various local exchanges. It was Mr. Tetu who made the black dress and short skirts a compulsory working costume for the telephone girls of Chicago, which raised a howl of indignation that would have daunted a man of less altitude of spirit than Mr. Al. Tetu.

COMMERCIAL PARAGRAPHS.

The Mather Electric Company of Manchester, Conn., have secured through Mr. J. Holt Gates, of Chicago, their well-known Western contractor, the order for five 100 k. w. Multipolar Generators, with station equipment, for the new station of the Indiana Electric Railway Company at Goshen, Ind. This contract was secured against the strongest competition, and reflects great credit on the success of Mr. Gates as a hustler and the merits of the new Mather Multipolar Apparatus.

The Metropolitan Electric Company have been appointed agents for the Solar Arc Lamp, a lamp of unusual merit for incandescent circuits. Its feed mechanism is so simple and adjustable that it has been found to be a most thoroughly economical and practical lamp. It is simple in construction, has a positive action of feed. no springs or dash-pot, no see-sawing. The lamp is manufactured plain or in various styles of ornamentation to meet requirements. Samples are being exhibited at the warerooms of the Metropolitan Electric Company, 186 and 188 Fifth avenue, Chicago, where they carry a stock for immediate shipment. Prices are made to suit the times.

Looking for Larger Quarters.

(From the Elgin (Ill.) News.

The Standard Electric Company of Chicago, which has been negotiating for the purchase of the Mason Air Brake Company's plant, is rated way up by Dun's commercial report. The company is accredited with capital from $200,000 to $300,000 and its general credit is placed "high." The company will employ 200 to 300 men. It has made the present owners a bona fide offer and the sale is very near consummation.

A New Water Wheel Governor.

For many years, in fact almost from the time when water power first began to be utilized in the operation of the more modern types of machinery, engineers and all others interested have more or less appreciated the difficulties attendant on the governing of the various kinds of water wheels. And the impossibility hitherto of effecting anything like close governing has proven to be the chief hindrance in the way of a more general utilization of the many splendid water powers that have long been available in this and other countries. Many attempts have been made in past years at solving this problem, but with only moderate success. Still there has been a slow but certainly increasing disposition and determination manifested among engineers, capitalists and manufacturers to make the best use of a limited amount of knowledge and skill, hence the increase of factories, etc., now run by water power everywhere. Vast and useful improvements in the manner of constructing and installing turbines, have been made of late years, and it is owing to these improvements almost solely that development has been possible. With the appearance on the market of a governor that really governs, and by the aid of which perfect control of the turbines is had, an impetus is being given to the work of utilizing waterfalls the like of which was never before seen or known. The accompanying illustrations show the details of the latest governor yet put into active service.

By referring to Figs. 1 and 2, it may be seen that the Lombard Water-Wheel Governor consists essentially of a hydraulic piston which applies its thrust in either direction to the rack, pinion and gears at the left side of the machine. These gears transmit the motion of the piston to the gate mechanism of the turbine.

The actuating force which operates the hydraulic piston is air compressed under about fifteen atmospheres (210 lbs. gauge pressure). This air is contained in the cylindrical tank under the bed plate of the governor and the pressure is maintained by a pump operated by the band wheel, shown on the rear side of the machine in Fig. 1 and on the front side of the machine in Fig. 2.

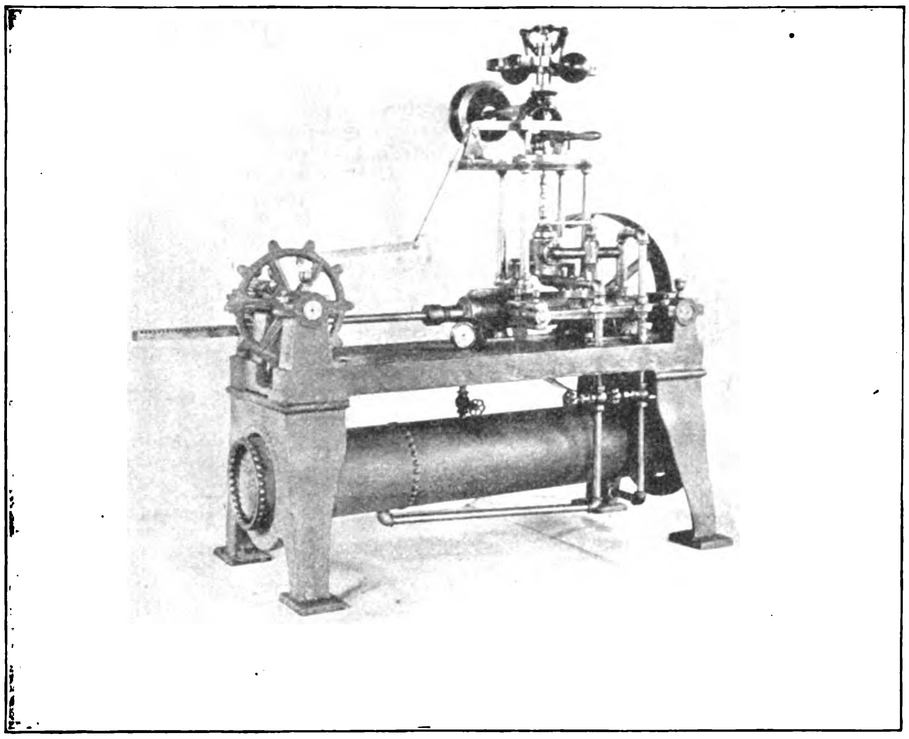


Fig. 1—Type A Governor.

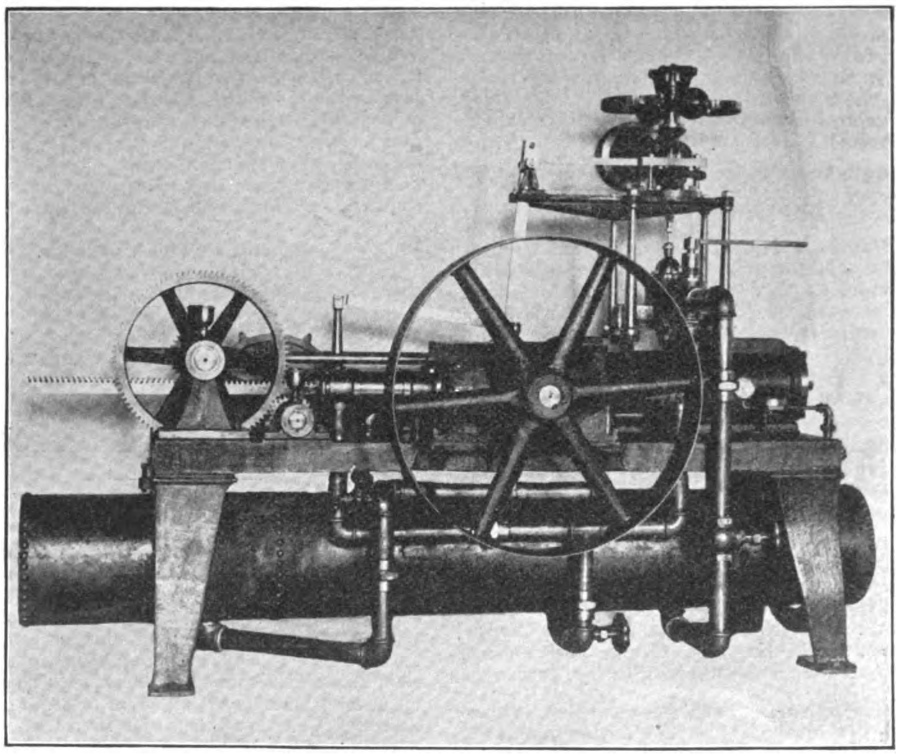

Fig. 2—Type C Governor.

The centrifugal governor balls actuate a perfectly balanced piston valve which stands in the circulating system. This valve has a lap of one-sixty-fourth of an inch, and a motion of that amount one way or the other, as the speed varies, causes the hydraulic piston and train of gears to open or close the gates of the turbine.

The mechanism of the valve motion is such that the full amount of motion due to the position of the balls is not used: in other words, the governor does not continue opening or closing the gates of the turbine until the centrifugal balls have resumed their normal position, but stops at such a position that when the various inertia forces have been absorbed the turbine gates will be in the proper position for the new load.

This peculiar motion of the valve is positive, automatic and adjustable, and gives perfect control of the turbine no matter how great the variation of load. By this it is not meant that this governor will hold a wheel to an absolutely constant speed, but it gives a speed regulation that compares favorably with the best steam engine practice and marks the beginning of a new era in the art of generating power by turbines.

The Lombard Water Wheel Governor is made in several sizes which are precisely alike in principle of action but differ in power.

Type A governor, shown in Fig. 1, is the smallest size made and is adapted to governing one wheel with easily movable gates.

Type C governor, shown in Fig. 2, is the largest size so far made.

INCORPORATIONS.

The Inland Electric Railway Company, Bucyrus, Ohio—to construct a street railroad and operate it by electric or other motive power between Bucyrus and Annapolis, Ohio. Capital stock, $50,000. Promoters: M. J. Monnett, A. J. Scott, B. Beal, Edward Volrath, E. B. Monnett.

The name of the Cuyahoga Manufacturing Company of Cleveland, Ohio, has been changed to the Jandus Electric Company, with an increase in the capital stock from $25 000 to $100,000. The president of the new company is J. Potter, the secretary Charles H. Rockwell.

Electric Construction and Supply Company, New York City. Capital stock, $12,000. Directors: Arthur A. Lawrence and Charles F. Parmly of New York City, W. S. Perry of Staten Island, and Charles E. Rocap and Frank Kinsman of Plainfield, N. J.

The Hamburg Railway Company, Buffalo, N. Y.—to build and operate a street surface road, one mile long. Capital stock, $10,000. Promoters: Wm. Elwood, S. H. Koopman, D. W. Allen, Buffalo.

The General Electric Light and Power Company, Le-Sueur, Minn.—to construct and operate an electric light plant at Le Sueur, Minn. Capital stock, $25,000. Promoters: Wm. H. Patten, Wm. A. Patten, W. H. Tomlinson, H. F. Weisx, E. H. McLeod, Le Sueur.

The Yankton Electric and Manufacturing Company, Yankton, S. D.—to own and operate an electric plant. Capital stock, $40,000. Promoters: John MacGregor, R.R. MacGregor, Otto R. Brandt, of Yankton.

The Pacific Power Company, San Francisco, Cal.—to purchase, sell and lease property; generate, manufacture and furnish electricity for lighting and other purposes. etc. Capital stock, $500,000. Promoters: W. A. Aldrich, San Francisco; G. W. Howard, San Mateo, Cal.; A. W. Bowman, Oakland, Cal.

The Peter Ballingall Company, Atlantic City, N. J.—to build, construct, enlarge or complete, or cause to be built, etc., railroads, gas works for light and heat, and electric light works for light, heat and power. Capital stock, $60,000. Promoters; Peter Ballingall, Wm. Martin, Jas. Brown, of Philadelphia.

The Mississippi Valley Harrison Telephone Company. Grand Rapids, Mich.—to engage in a general electric telephone business and sell rights to patents. Capital stock, $100,000. Promoters: J. M. Beakesly, T. Stewart White, Wm. T. Hess, of Grand Rapids.

The Wellsville Electric Light Company, Wellsville, Ohio—to manufacture, sell and furnish electric light, power and heat in Wellsville. Capital stock, $30,000. Promoters: Homer Laughlin, W. E. Wells, R. L. Andrews, Julius Goetz, H. C. Wells.

The Parkersburg Traction Company, Parkersburg, W. Va.—to build and operate a street railway in Parkersburg, with branches and extension. Capital stock, $1,000,000. Promoters: D. B. Judd, Wm. R. Hurd, Wm. C Spring, Bristol, Conn.

ELECTRICAL PATENT RECORD.

Letters Patent Issued March 19, 1895

ELECTRIC RAILROADS AND APPLIANCES.

535,936. Conduit Electric Railway. Fred P. Bergh and Charles W. Tarbox, New York, N. Y., assignors to David Calman, same place. Filed May 25, 1894.

535,971. Insulated Trolley Section and Crossover. Montraville M. Wood, Chicago, Ill., and Charles K. King, Mansfield, Ohio, assignors to the Ohio Brass Company, Mansfield, Ohio. Filed July 13, 1894.

535,993. Closed-Conduit Electric Railway. James F. McLaughlin, Philadelphia, Pa. Filed Oct. 23, 1894.

536,055. Apparatus for Automatically Limiting Speed of Electric Cars. Louis S. Wright, Philadelphia, Pa. Filed Dec. 8, 1894.

536,076. Collapsible Conduit for Electric-Railway Conductors. Harry C. Grant, New York, N. Y. Filed Sept. 17, 1894.

ELECTRIC LIGHTS AND APPLIANCES.

535,838. Incandescent Electric Lamp. William S. Lowe, Lima, Ohio. Filed Oct. 15, 1892.

535,840. Electric-Arc Lamp. George R. MacIntyre, New York, N. Y. Filed July 5, 1894.

535,841. Electric-Arc Lamp. George R. MacIntyre, New York, N. Y. Filed July 5, 1894.

535,842. Electric-Arc Lamp. George R. MacIntyre, New York, N. Y. Filed July 10, 1894.

535,933. Street-Sign for Electric Lights. Robert S. Wright and Henry C. Bradford, Somerville, Mass. Filed Feb. 23, 1894.

536,081. Cord-Adjuster for Electric Lights, etc. Milton B. Hood, Montclair, N. J. Filed May 26, 1894.

DYNAMO ELECTRIC MACHINERY.

536,082. Alternating-Current Motor. Maurice Hutin and Maurice Leblanc, Paris, France, assignors to the Societe Anonyme pour la Transmission de la Force par l'Electricite, same place. Original application filed Nov. 17, 1892. Divided and this application filed Feb. 14, 1895.

TELEPHONE AND TELEGRAPH APPARATUS.

535,810. Spring-Winding Means for Printing-Telegraph Instruments. John Burry, Long Island City, N. Y. Filed May 12, 1894.

536,100. Automatic Toll-Box for Telephones. Howard C. Root, Brooklyn, N. Y. Filed Nov. 30, 1894.

MISCELLANEOUS.

535,856. Dynamometer. Benjamin F. Perkins, Holyoke, Mass. Filed March 2, 1894.

535,865. Electric Sign-Changing Device. William Sears, Boston, Mass. Filed Feb. 19, 1894.

535,885. Accumulator-Plate. Georges R. Blot, Paris, France. Filed May 22, 1894.

535,948. Electric Program-Clock. Fred Frick, Waynesborough, Pa. Filed May 28, 1894.

536,091. Dynamometer for Mechanical Musical Instruments. Max Lochmann, Leipsic-Gohlis, Germany, assignor to Kraft Behrens, same place. Filed March 20, 1894.

536,095. Protective Device for Electrical Appliances. Joseph J. O'Connell, Chicago, Ill., assignor to the American Bell Telephone Company, Boston, Mass. Filed Nov. 23, 1894.

536,104. Electromagnetic Signal. Theodore Spencer, Cambridge, assignor to the American Bell Telephone Company, Boston, Mass. Filed Sept. 10, 1894.

536,153. Tip for Flexible Electric Conductors. Charles H. McEvoy, Lowell, Mass. Filed Feb. 4, 1895.

ELECTRICITY.

VOL. VIII. NEW YORK, APRIL 3, 1895. No. 12

ELECTRICITY

Published every Wednesday by the

ELECTRICITY NEWSPAPER CO.

B. E. GREENE, PRES'T. L. J. MONTGOMERY, SEC'Y.

PUBLICATION OFFICE:

6 Park Place - New York

EDITORS: NELSON W. PERRY.
BURTON E. GREENE.
R. H. WILLOUGHBY.

BUSINESS MANAGER, - - JOHN L. GANS.

SUBSCRIPTION RATES:

UNITED STATES,	$2.50
IN CLUBS OF FIVE OR MORE,	$2.00
FOREIGN COUNTRIES,	$4.50
SINGLE COPIES.	10 CENTS

ADVERTISING RATES:

As ELECTRICITY reaches all classes interested in electrical work, its value as an advertising medium can be readily appreciated. Rates will be sent on application.

Changes for advertisements should reach the office not later than the Saturday preceding the date of publication.

ENTERED AT THE N. Y. POST OFFICE AS MAIL MATTER OF THE SECOND-CLASS.

EDITORIAL NOTES.

NO DEFINITE results have yet been reached in the negotiations going on between the Westinghouse and G. E. companies. The accounting departments of both companies practically finished their special work last week, having been engaged for several days, including Sundays, until late at night.

No further details are given out as to the scope of the proposed arrangement, and the opinion of one outsider is as good as that of another.

ELECTRICITY'S views are already on record. An arrangement might be made of immense benefit to every one in the trade; it might, on the other hand, result in a policy which would breed nothing but disaster.

We have reason to hope that the common sense and good management displayed by the active heads of the Westinghouse interests for the past three years will prevail, and that the visionary bankers will not precipitate their own funeral.

The annual reports of the two companies will be out in a few weeks, when the common stockholders will presumably be advised as to the entire plan.

* * *

The Tesla Oscillator. It seemed an exceedingly bold step for Mr. Tesla to take in departing from the rotary type of generator to the reciprocating, at least when we consider the step from the standpoint of efficiency and economy. It has been rather accepted as axiomatic by the steam engineering profession, that the reciprocating feature of the steam engine was a weakness which it was very desirable to overcome, but that the difficulties encountered in all attempts to depart from these established types were greater than any advantages which were practically attained by the rotary type. So strong had this conviction become that all attempts to produce a rotary steam engine were looked upon with suspicion, and we remember a recent engine which was advertised somewhat extensively at the time as not being a reciprocating engine and yet not a rotary one, it evidently being considered inadvisable to burden the machine with the disfavor which so generally attaches to the rotary engine.

With the electric motor most of the early attempts were of the reciprocating type, if we except a few of those such as Barlow's wheel, and others evincing but little power, but with the development of the modern rotating armature a great advance was realized and the tractive effort exerted by the modern electric motor as applied to street railways was soon noticed to so far exceed that from a reciprocating type as to lead many to endeavor to account for it on the ground of a magnetic relation between wheel and track—to incipient welding between the two, etc., etc. So far superior for most purposes was the rotary type regarded that the announcement was received with no little surprise that Tesla had deliberately discarded it. But when we consider that the electrical part of this combination is not the motor part, but the generator, and that the currents desired are of the reciprocating kind, it does not seem illogical that the efficiency should be greater than could be expected from the ordinary method, which involves a reciprocating engine whose motion is converted first into a rotary one and that this again is practically converted back into reciprocating. It seemed a bold step, however, and it is safe to say that it was only the great confidence which the engineering profession had learned to have in anything which Mr. Tesla was willing to stand sponsor for that prevented hostile criticism from being general. As it was, the public and the profession tacitly agreed to withhold criticism until Mr. Tesla had completed his work, and now that the immediate fulfilment of his desire to give to public gaze his completed machine has been delayed by the unfortunate catastrophe, public attention has been again aroused in this new machine. Mr. Tesla has never once lost faith or confidence in the outcome of this his latest undertaking, and it was not long since that in conversation with the writer he expressed the opinion that this, the oscillator, was the most important work of his life. Just at this time, therefore, Mr. Martin's article in the April *Century Magazine* on "Tesla's Oscillator and other Inventions," from which we are enabled by the courtesy of both the publisher and the author to reproduce the latest photograph of the completed machine, comes with great appropriateness, and will attract wide and deserved attention.

In regard to the oscillator, Mr. Martin says:

"Mr. Tesla, to begin with, has stripped the engine of all this governing mechanism. By giving also to the coils in which the current is created, as they cut the lines of force of the magnets, a to-and-fro or reciprocating motion, so that the influence on them is equal in every direction, he has overcome the loss of the idle part of the wire experienced in rotating armatures; and moreover, greatest achievement of all, he has made the currents regulate the mechanical motions. . . In the Tesla oscillator . . . the vibrations of the current are absolutely steady and uniform. . . Back of the tendencies to irregularity in the old-fashioned electrical apparatus were the equal or greater tendencies in the steam engine, and over and above all were the frightful losses due to the inefficient conversion in both of the power released from the fuel under the boiler generating the steam. . . We note immediately the absence of all the governing appliances of the ordinary engine. They are non-existent. The steam chest *is* the engine. . . Moreover, for the same pressure and the same piston speed, the engine has about one-thirtieth or one-fortieth of the usual weight. . . This diminution of bulk and area is equally true of the electrical part. . . What we are dealing with here is a dual, interacting machine, half mechanical, half electrical, of smallest bulk, extremely simple, utilizing steam under conditions unquestionably of the highest efficiency, its vibrations independent of load and pressure, delivering currents of the greatest regularity ever known for practical work or research. That such a combination should produce electricity for half the consumption of steam previously necessary with familiar apparatus in equivalent results need not surprise us."

* * *

A Return to Reason. Since Electricity was the first journal in America to promulgate the correct view of the possibilities of the Niagara transmission scheme, it is with a certain sense of satisfaction that we notice the reaction which has set in against the wave of popular fallacies which swept over the country two years ago in regard to this scheme. The ridiculous estimates of Messrs. Houston and Kennelly, given weight by their publication in the *Electrical Engineer*, were sufficient to prevent the ordinary daily paper editor from doing any thinking on his own account.

Now, however, there has been so much discussion that many of the latter are using their own horse-sense, which is sometimes more valuable than theoretical technical knowledge. The fact that the Niagara Falls Power Company has so far been unable to offer any inducement to the city of Buffalo in the shape of guarantees as to the cost of the current distributed there, is also becoming known, and it does not require much knowledge to know what this means.

Among the particular examples of newspapers who are returning to a common sense view may be mentioned the New York *Tribune*, the Philadelphia *Press* and the Rochester *Democrat and Chronicle*.

The Niagara Company has opportunities for a successful commercial venture in the sale of current at its very doors, and has already made some money out of its land speculations. When it goes beyond its proper field it will meet with disaster.

But we suppose, like many other electrical enterprises, the backers of the Niagara scheme had to misrepresent and multiply its possibilities in order to sell stock. If enough could be sold the backers would come out even, and the public would once more be taken in.

* * *

A Trolley Decision. A decision rendered by the Supreme Court of Pennsylvania last week will, if held to be good law in other States, seriously retard the work of many interurban lines now projected, and put a damper upon that entire branch of the business until the Legislatures shall have passed a special law to cover the rights and privileges of the trolley companies. The decision holds that the private property of every landholder abutting on the country highway covers the highway itself except for the purposes of passage in the regular use of the road. This makes it incompetent for an electric road to lay its tracks on country roads "*except by contract with every owner of property along the roads they wish to occupy.*"

A company proposing to build a line between two towns or villages must halt until it has obtained the consent of every owner of property abutting on the roads it wishes to traverse. This is, of course, a practical impossibility for a line running for any distance through the country.

Electric lines already built in the country can not be disturbed, as the Court holds that the property owners have the remedy of a suit at law for damages.

There have so far been few objections from the farmers themselves to having an electric line built on the roads fronting their property. But the law is now laid down, and will doubtless be found to apply in many other States.

What is needed is new legislation. This will, of course, encounter the organized opposition of the steam railway interests, which interests have been in control at Harrisburg for a generation.

The trolley, however, has won a popular victory everywhere except in New York City. In country districts it has added to the comforts of life, has promoted trade, and provided the mechanic and the artisan with a way to reach a clean home, relieving him from the necessity of living close to his workshop. It has given millions of people of moderate means an opportunity of breathing the fresh air which they could get in no other way so well.

The extension of a system which has been so universally received with favor cannot be stopped though it has been delayed.

* * *

The controversy now going on between the steam and electric road interests in Connecticut must eventually be settled upon the principle of the greatest good to the greatest number. Meantime, New York capitalists closely allied to the management of the N. Y., N. H. and H. Railroad are buying up local parallel electric lines, with a view to controlling as far as possible both sides of the case where their line is concerned.

The Carbon Business. That the National Carbon Company of Cleveland, which recently built the largest carbon factory in the world, are desirous of obtaining an exclusive monopoly in the manufacture of electric light carbons goes without saying. Such desire is natural, and in a business or moral sense beyond criticism. It should, of course, be a good thing for the stockholders of that company.

Whether it would be equally desirable for the consumers of carbons is an entirely different question, and we think admits of but one answer. Human nature is very much the same throughout the commercial world. Ambition to make profits as large as possible is ever-controlling. While this company are now selling their product in some places at reasonable prices, it does not follow that they would do so if they had the field to themselves. It would certainly seem to be to the interest of large consumers to patronize independent companies whenever possible, price and quality considered, and in the latter respect some of the independent companies are far in the lead—especially is this the case in the matter of cored carbons.

The management of the National Company has been and is shrewd—if that is the proper term. Through various ways and by various methods they have got what may be called a pull with many large plants. The consequence is that the largest consumers are in many cases paying more for their carbons than those using a very small quantity. A mild form of humbug, common with all trusts we believe, is practised in continuing to offer the brands of the various amalgamated companies after the latter have gone out of existence. Thus if a purchaser prefers T.-H. carbons over Standard, or vice versa, his taste can be suited, although the two brands are perhaps made in the same molds, by the same men and from the same material.

Not long ago they tried to corral the supply of coke, but found that they were no match for Mr. James Humbird in a game of this nature.

Sentiment often plays an important part in business, and it should have some consideration even in so prosy a one as the carbon business. In addition to this, however, there is the main question of self-interest to be considered by the purchaser. Do the central-station men of the country want their supply of carbons to be in the hands of an air-tight monopoly?

Electricity recommends that for many months to come these purchasers refrain from making long-time contracts. They will conserve their own interests by doing so, in that they will be in position to take advantage of changes in price, and will be able to know every week just what the price is.

* * *

The *Street Railway and Electrical News* for January is just at hand. The most interesting features are a report of the meeting of the Northwestern Association, held that month at Milwaukee, and a full page advertisement of the Great Western Manufacturing Company, which died last year.

Under the Searchlight.

Views and Opinions on Timely Topics.

UNANSWERABLE ARGUMENT.

One day in 1889 there was an important gathering of the leading clergymen of the Congregational faith in Plymouth Church, Brooklyn.

The day following General Pinto, a philosopher who is well known downtown in New York, was in the office of the Hon. Franklin Edson, and the following dialogue occurred :

Mr. Edson—General Pinto, what did you think of the deliberations of those clergymen in Plymouth Church yesterday ?

General Pinto—Oh, those fellows are off their base; they don't know what they are talking about.

Mr. Edson—General, how do you tell when a man is off his base ?

General Pinto—When he don't agree with me, of course.

Respectfully referred to Mr. Herbert Lloyd.

WELLINGTON ADAMS OUTDONE.

An Electric Road from Sea to Sea.

The Interocean Electric Railway Company has been incorporated by some breezy Chicago gentlemen. The capital stock is only $200,000,000. They will build (at once, of course,) an elevated freight line from New York to Chicago, extending it to San Francisco in the near future.

One of the promoters says :

> This road is a decided step in advance of the electrical roads operated at present. Electricity is cheaper as a motive power than steam and renders a much higher rate of speed possible. By elevating our road we expect to do away with the necessity of buying a right of way, and all delays incident to surface traffic will be avoided. At present it takes six days for freight to travel from Chicago to New York. On the new road the trip will take one. The road will have its own telephone and telegraph lines.
>
> A number of American and several foreign capitalists are interested in the road and building operations will begin soon. New inventions in electrical transportation will be used by the road, but I am not at liberty to disclose their nature. The capital, while large, is not out of proportion to the business we expect to do, but I cannot at present give the names of any of the persons interested.

Petty swindlers will now step aside and make room for the greatest fake of the century.

ELECTRICITY advises the " capitalists " who are in this scheme to get out at once, and those who are solicited to come in should kick the promoters out of their offices without ceremony.

It would be unnecessary to take this matter seriously if such papers as the New York *Sun*, with many others, had not done so, giving it one-third of a column in regular news matter and helping thus far in the gigantic swindling game—for it is nothing else.

* * *

WE WERE wont to look upon the Boston *Traveler* as a journal of the highest repute, using more than ordinary discretion as to what was admitted to both its reading matter and advertising columns. We now see that the *Traveler* has fallen from grace, putting itself on a par with the N. Y. *World* or the Cincinnati *Enquirer*. On Saturday, March 30, it carried a half-page advertisement of the Pennock swindle, which is not new, but has been denounced in every reputable electrical paper in America.

* * *

Intelligent Criticism.

(From the Lockport Sun.)

OFF ITS TROLLEY.

ELECTRICITY, a journal published in New York, estimates that Niagara power will cost $51 per horse-power delivered in Buffalo. The Buffalo *News* comforts itself with the reflection that the electricity used to propel the street cars there is transmitted and distributed over 125 miles of wire, and therefore ELECTRICITY is off its " trolley."

Truth Well Told.

(From the Pittsburgh Dispatch).

Notwithstanding the Pickwickian denials of the reported combination of the great electric companies a week or two ago, the arrangements were officially announced yesterday. The combination outlined in our news columns includes an adjudication as to ownership of existing patents, the mutual payment of royalties, a division of territory and a schedule of prices to be in force all over the country.

This indicates a set determination on the part of the great corporations to prevent the reduction of prices that would naturally follow the recent Supreme Court decisions. But while the agreement may be effective on that part of electrical manufacturing still controlled by patents, the fact that a great portion of the trade is thrown open to general competition will defeat any attempt to sustain excessive prices. Agreements to pay royalties can be enforced by law, but contracts to divide territory and hold prices at an arbitrary scale have been proved by experience to be little better than a bruised reed, unless there is back of them some power to smother new competition.

It is well, therefore, to wait and see what the combination will amount to in actual practice. It does not seem likely to defeat the salutary rule that the business concern which gives the public the most for its money will get the largest share of the business.

* * *

Keep on Looking.

The Leads are There.

(From " Electricity," London.)

In connection with the Cleveland Electric Lighting Convention, ELECTRICITY of New York has blossomed forth with a special and marvelous wrapper. A young lady, who does not look very comfortable, is lying with her back on a footstool and her legs in the air (perhaps I had better mention that she is wearing tights). One foot supports a gigantic arc lamp, but for the life of me I have been unable to discover the leads.

* * *

A YANKEE WIZARD.

The Amperes Are Safe in His Apparatus.

(From the St. Louis Globe-Democrat. March 27.)

VALUABLE ELECTRICAL APPARATUS.

NEW HAVEN, CONN., March 26.—J. J. Morgan, employed in the Mechanical Department of Yale Scientific School, has invented an apparatus by means of which the use of the motor dynamo invented by Edison is obvious. The amperes reduce the voltage of a current without lessening the apparatus. A test made to-day reduced an electric light current of 100 volts four amperes to seven volts, without affecting the amperes.

* * *

Is This Authentic?

(From the Wall Street Daily News.)

That a better understanding between the companies would be of great value to each goes without saying, but efforts heretofore made to bring this about have always encountered the bitter opposition of Mr. George Westinghouse, who swore "I will have nothing to do with the General Electric concern as long as that man Coffin has anything to do with it."

Mr. Westinghouse does not swear.

* * *

THE New York Edison Company (Licensees) announce that hereafter they will have nothing whatever to do with the sale of apparatus in their territory, nor with construction work. They have returned these privileges to the G. E. Company. We suppose the consideration was the consent of the latter company to the $15,000,000 bond issue, which is forbidden under the licensee contract.

* * *

THE Western Electric dynamos in the Detroit city plant are to be started this week. The initial experiments with Engineer Dow's entire system will be of considerable interest.

* * *

The New Bear Argument.

(From the Financial News.)

Take it all in all, the new bear argument on the stock exchange may be ELECTRICITY.

* * *

The Same Old Lie.

(From the " Times-Union," Jacksonville.)

ELECTRICITY is still in its infancy.

A Valuable Opinion.

(Interview with Mr. Samuel Insull in a Chicago paper.

I heard nothing of the proposed Trust while I was in New York and am inclined to think there is little, if any, truth in the reports telegraphed here. I was in the offices of the General Electric Company as late as 8 o'clock on Tuesday afternoon.

In 1892, when Mr. Insull was closer to headquarters than at present, he had not heard of the G. E. combination until it was closed.

* * *

THE formation of the G. E. Company was an effort to upset all the laws of business which men have been taught. The continuation of the company is simply prolonging the dying agonies of that effort. *It can not win.*

* * *

PUDD'NHEAD'S PHILOSOPHY.

Bate Case only a Bunco Game.

F. P. Fish and Leonard E. Curtis were the *Steerers* we Suppose.

(From the Electrical World, March 30.)

Owing to the vast amount of misinformation contained in the newspaper interpretations of the recent decision of the United States Supreme Court in the Bate Refrigerating case, and, in scarcely a less degree, to the editorial remarks of some of our electrical contemporaries on the same subject, a very considerable misunderstanding exists in electrical circles in regard to the real significance of the decision. It is somewhat singular how the importance of this case has been magnified, and the unwarranted conclusions that have been based upon its final settlement. The Bate case, in short, may be considered as little more than a "bunco" game played upon credulous clients by their legal advisers, and THE DECISION OF THE COURT HAS HAD ABSOLUTELY NO EFFECT UPON ANY PATENT WHATEVER, EITHER IN THE PAST, PRESENT OR FUTURE. Section 4,887 of the Revised Statutes declares that a domestic patent expires with a foreign patent on the same invention if the date of the latter is prior to the date of issue of the domestic patent, and the attempt to substitute *application* for *issue* was SO DEVOID OF REASON that it never had an iota of chance of favorable consideration by the Supreme Court. . . . A statement, therefore, of the effect of the Bate case is that it affected nothing whatever—the decision merely registering the failure of an attempt to change existing law. The Edison telephone patents and the Edison lamp patent, for example, which expired in 1892 and 1894 respectively, were no less null before the decision than after it.

Now we know what's what, and the next time James C. Carter, J. J. Storrow, C. E. Mitchell, Wheeler H. Peckham, B. F. Bristow and Edmund Wetmore, and the United States Supreme Court want to know just what the law is they will please report at once to Pudd'nhead in his sanctum.

The Bate case was finally argued in Washington during the week ending November 17 last. It was decided on Monday, March 4. Between those two dates, *for nearly three months*, the business of a dozen lamp companies was suspended and several eminent United States Circuit Court Judges had refused to raise injunctions.

Yet according to our perspicacious contemporary the decision *affected nothing whatever*.

The most eminent counsel in the United States were employed for months on the case at an expense all told of over $50,000, and yet the contention was *devoid of reason*.

Oh, Pudd'nhead, O'Johnston.

Personal.

Mr. Wm. Lemont, one of the leading and most enterprising citizens of Fredericton, N. B., paid us a visit last week. He states that electrical interests are making steady progress in the Canadian provinces of New Brunswick and Nova Scotia.

Mr. Godfrey G. Luthy, of the Royal Electric Company, Peoria, who has been in the city for several days, has returned to the West.

THE TESLA OSCILLATOR.

In view of the recent destruction by fire of Mr. Nikola Tesla's laboratory, with all the apparatus therein contained, some of the mechanism most nearly completed and perfected that has gone has been given an additional interest. There is probably no device of Mr. Tesla's of recent date around which more interest has centered than the electrical oscillator, which he first exhibited before a select audience at the World's Fair during the occasion of the Electrical Congress.

Since those instruments were exhibited the mechanism has undergone a considerable change, not in principle but in detail, which has tended to make it more compact, more efficient and in every way better adapted to the peculiar requirements of experimentation in which Mr. Tesla has been engaged as well as to the everyday requirements of the commercial machine. To such an extent had his work been carried in this line that Mr. Tesla was about ready to put the apparatus on the market, and did in fact for some time previous to the fire have his oscillator in practical service in his laboratory.

Through the courtesy of the *Century Magazine* we are enabled to reproduce here an engraving of the latest type of this machine, made from the last photograph taken of it, which, now that the machine itself has been destroyed, will have additional interest for our readers. This picture was made to accompany an exceedingly well written article by Mr. T. C. Martin which appears in the April number of the *Century*, to which our readers are referred. Mr. Martin, as is well known, is Mr. Tesla's historian, and any statements coming from him in regard to Tesla's work are therefore authoritative.

The Tesla oscillator is a steam mechanism, but the "engine" part may be said to have disappeared, so far as that word implies an aggregation of fly wheel, governors, etc. On the one base were mounted two dynamos, or electro-magnetic generating systems, and a small steam chest. There were two pistons, which were vibrated by the steam 80 to 100 times a second. Each of the pistons carried an armature which was plunged reciprocally into the field of the magnets. Normally the engine was run with the two pistons in opposite phase, but they could be set by an independent device in any phase. Above the chest was mounted an independent little oscillator, which in some experiments controlled the steam admission, and made the vibration of the engine quite independent of the load.

This oscillator was operated with steam at 350 pounds pressure, when it needed no packing, as there was no leakage. It was also used at pressures down to the ordinary 80 or 100 pounds. It was used to light up a bank of 50 or more incandescent lamps, some arc lamps, and to run various motors, while it also furnished current for a variety of most interesting and novel experiments, all of them suggestive of new departures in the electrical arts, including phosphorescent lighting, the transmission of intelligence long distances without wires, the utilization of the earth's electrical charge, etc.

Copyright, 1895, by THE CENTURY CO.

THE TESLA OSCILLATOR.

For a $15,000,000 Mortgage.

In a circular asking the stockholders of the Edison Illuminating Company of New York for authority to create a mortgage of $15,000,000, figures are given indicating the larger growth of the company's business and earnings in comparison with the increase in capital invested.

The increase in net earnings in five years is claimed to be 537 per cent., while the capital was increased only 308 per cent. The mortgage proposed will authorize the retention of $8,500,000 bonds in the treasury for future use for new construction and acquisition, but they may not be issued to an extent exceeding $1,000,000 in any one year and the first issue shall not be made before January 1, 1896. Only $1,686,000 new bonds are to be issued immediately, to reimburse the company for final payments on its Harlem and Manhattan companies' purchase and to provide funds for the construction requirements of the present year. The stockholders will meet on May 1.

SOCIETY NEWS.

Prof. Crocker's Second Lecture at Columbia College.

The second of Prof. Francis B. Crocker's popular lectures on "How Electricity is Now Being Utilized" was delivered at Columbia College on Thursday evening last. The subject was "Alternating Currents" and was handled in a concise and comprehensive manner. Beginning with the fundamental principles, Prof. Crocker gave an elucidation of his subject that was quite clear even to laymen. The peculiar phenomena of alternating currents were demonstrated by a series of interesting experiments which were made more striking by contrast with direct current phenomena. Notwithstanding Prof. Crocker's well known predilection for the direct current, he did not hesitate to say that "the alternating current is of special importance, for it is certain to be the current of the future, if it is not already the current of the present." This endorsement was made with the qualification that, inasmuch as the future will witness the application of many electro-chemical processes, the utilization of the alternating current in these operations will be prohibited by the fact that the direct current is the only one by which chemical changes can be produced.

Mr. Freedman at the A. I. E. E.

At the rooms of the American Institute on West 38th street on Friday evening W. H. Freedman, E.E., president of the Electrical Section, in conjunction with the Henry Electrical Club, gave a very instructive talk on "Electric Railways." He traced the history and development of the art from the days of Davenport down to the present, illustrating his remarks by the use of lantern slides.

The next meeting of the Section will be held April 12, at which Prof. L. H. Laudy, first vice-president, will discuss the subject of "Meters."

The Walker Company Won.

The Union Depot Railway Company of St. Louis, through its general manager, Harry Scullin, has signed a contract for a 1,500 kilowatt generator with the Walker Manufacturing Company of Cleveland, Ohio. There were three bidders, the Westinghouse, General Electric and Walker companies.

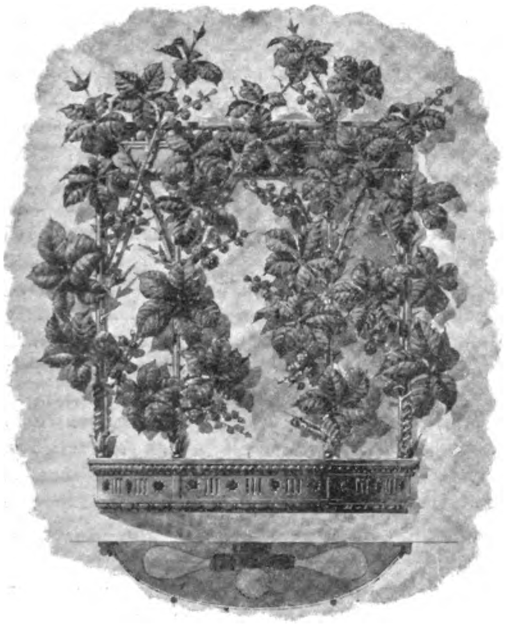
The Union Depot Railway Company have nearly 75 miles of single track. Their two power-houses are entirely equipped with G. E. apparatus and the 400 cars are all of G. E. equipment. They have lately bought 45 car equipments of the Walker type.

DECORATIVE LIGHTING.

A Fertile Field for Architects and Designers.

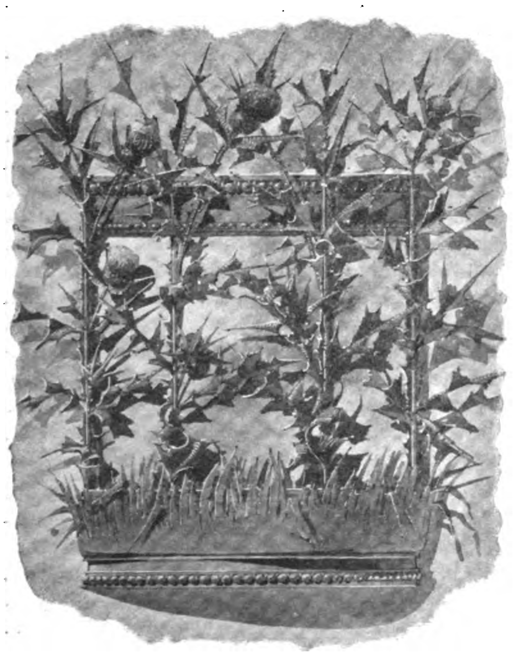
B. E. G.

The publication of Mr. Bernard's admirable article on "Church Illumination" in ELECTRICITY suggested a field of effort for fixture makers and others which has been so far scarcely cultivated at all. There are scores of large and richly designed places of worship in the country which could be rendered four-fold more attractive, without detracting in the least from the sacred character of the edifices themselves, by properly placed electric lights with artistic fittings, and by various effects from concealed lights. While the Catholic and Episcopalian forms of worship render the interiors of the churches of these denominations more distinctly available for the embellishment suggested, there is no valid reason why Protestant churches should not fall into line and adopt the means at hand for making the interiors of their houses of worship more attractive in being more beautiful.



1.—WALL ELECTROLIER.
Wrought Iron, Hammered Leaf.

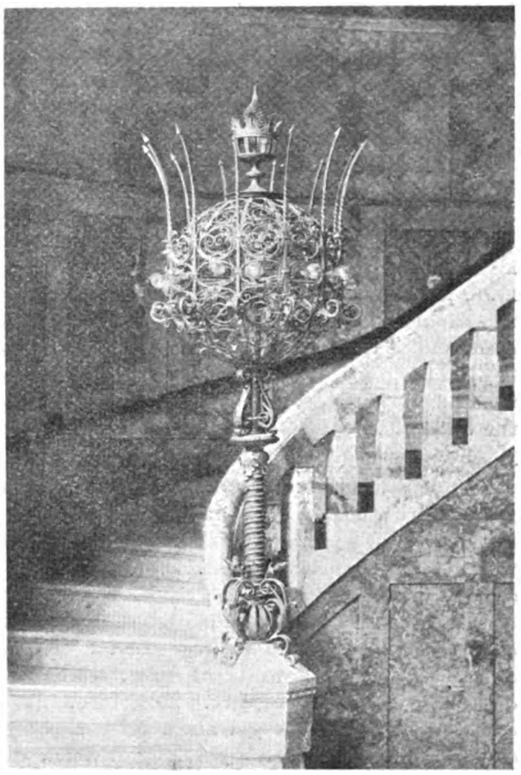
This is a field, however, particularly reserved for the genuine artist, and which amateurs would do better not to enter.



2.—WALL ELECTROLIER.
Wrought Iron, Hammered Leaf.

In the accompanying illustrations we are enabled to present for the consideration of architects and engineers suggestions as to what may be accomplished in the way of decoration for large public buildings or for private residences.

How few of the magnificent office buildings erected during the last few years have had the benefit of any taste or skill whatever in this line. Yet the difference in cost between an artistic plan of lighting and the suspension of ordinary arc lamps in large areas is not great. It is not the added cost, we think, which has stood in the way of further development in this direction, but the fact that the architects and engineers have paid little attention to it, and that the builders themselves rely on the former for suggestions of this nature.



3.—ELECTROLIER AND NEWEL.
Wrought Iron, Hammered Leaf, Bower-Barffed.

Of course the ornamental arc lamps of the period are a great improvement over the ugly original devices which were tolerated so long, but for really artistic effects the incandescent lamp must be chiefly relied on.

Fixture makers, we are sure, can extend their work in this direction to the enhancement of their own profits and to the public good, as everything which tends to make the surroundings of our daily life more beautiful, more artistic, is to the public good, raising us to a higher plane of civilization and culture.

The illustrations presented are taken by permission from *Ornamental Iron*, published by the Winslow Bros. Co., Chicago.

Good Chance for a New Plant.

At the annual election of officers of the Newburg, N. Y., Edison Company last week, the local element was completely frozen out of the directorate, and Mr. C. T. Hughes was chosen president, Henry W. Darling vice-president, H. M. Francis secretary, and W. H. Clark treasurer. The president comes from New York. The vice-president, secretary and treasurer hail from Schenectady. The fifth director resides in Canada, where he looks after the interests of the General Electric Company.

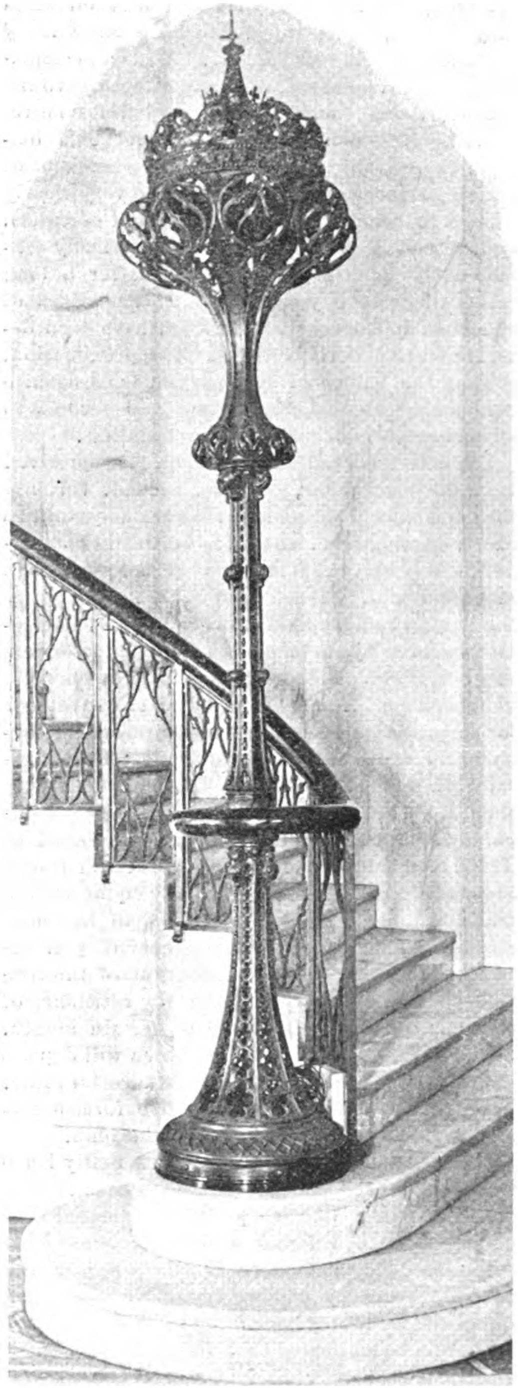
The arbitrary action of the G. E. people has aroused a storm of popular indignation. The newspapers of course are on the side of the local holders, many of whom are leading capitalists of the town. The plant was originally sold by Mr. Hughes several years ago.

It looks as though Newburg was ripe for the establishment of a new plant.

The Scientific Foundations of Electrical Engineering.*

BY F. G. BAILY, M.A.

There is probably no branch of engineering which is more intimately connected with purely scientific knowledge, and which has received more attention from scientific men than electrical engineering. The novel character of the forces which it employs, their intangibility and mysterious nature, appeal strongly to the imaginations of the uninitiated, and seem to set apart everything connected with electricity as a class of phenomena about which very little is known or understood. On the other hand, a certain amount of familiarity with the more usual phenomena, and the acquisition of several formulæ has produced in some minds a profound conviction of the truth of electrical theories, with an implicit faith in the accuracy of electrical measurements and the potency of calculation. While leaving the former attitude of mind to the gradual effect of familiarity, I wish to mention in this paper some of the limits to which we are



Decorative Lighting.
4.—ELECTROLIER AND NEWEL.
Statuary Bronze.

---

*Paper read before the Northern Society of Electrical Engineers, 11th March, 1895.

still subject, and some of the errors to which we are specially liable.

The most powerful aid to improvement, and the greatest source of confidence in engineering practice, is undoubtedly by accuracy of measurement of effects and quantities in units which are common to all branches of physical knowledge. It is, therefore, useful sometimes to examine our foundations and realize what they mean.

In accordance with its close connection with pure science, the units employed in electrical engineering have been based on the so-called "absolute" system of units—that in which the centimeter, gramme and second form the fundamental quantities, the definitions of which depend on the physical properties of certain portions of the universe. Physical science refers all its measurements to these three fundamental units, and recognizes no others. As these units are independent, all calculations based on them may be accepted as rigidly accurate and strictly comparable with one another. Abstract calculations are not, however, of much direct use to the engineer, and something more definite is required. Now the electromotive force of a battery, the current in a lamp, or the resistance of a piece of wire does not appear to be very closely related to grammes, centimeters and seconds, and, in fact, they can only be numerically estimated by indirect experiment. After a long series of extremely careful work, the values of electrical and magnetic quantities have been determined to a certain degree of approximation, so that the values of any particular resistance can be expressed in centimeters and seconds to an accuracy of ·01 per cent., or even less.

The electrical and magnetic units are derived from the centimeter, gramme, second, through the mechanical forces which the various quantities exert, starting from the force between two magnetic poles and the force on a magnetic pole in a magnetic field. Hence current is measured by the strength of the field it produces, and electromotive force by the motion of a conductor in a magnetic field. Resistance is defined as the ratio of these two. This system, however convenient for scientific purposes, does not lend itself readily to the reproduction of the units. In practical work it is important that the standard values should be readily reproduced and easily compared to others. On this account the Board of Trade have laid down that the practical standards, while being made as closely equal to the true absolute values as possible, shall be independent of them and independent of possible future more accurate determinations of the true values. The ohm is defined as the resistance of a certain quantity of mercury of certain length, and the ampere as a current which will deposit silver out of a certain solution at a certain rate. The volt is then the electromotive force necessary to drive one ampere through one ohm.

In accepting these definitions we really leave the centimeter-gramme-second system, and found another one very closely related but arranged on a different and more convenient principle. To what extent is this accurate, and to what accuracy can we compare electrical quantities on this system ?

It must be confessed that the measurement of electrical quantities has not the same accuracy as the measurement of the fundamental mechanical quantities, and the laws upon which they depend are not to be depended on to the same extent. The laws of motion laid down by Newton have an accuracy which may almost be regarded as absolute. We have no reason for doubting them. The standards of length and mass may conceivably alter in the course of ages, but there is no evidence of such a change having taken place. But the electrical units are not so firmly established. The electrical resistance of standard ohm coils has been found to vary to a small extent, but this unit is the most satisfactory one, and comparisons between it and others can be made with considerable accuracy, one part in 10,000 being easily obtainable. The standard current depends on Faraday's law of electrolytic action, and though this may be theoretically very approximately true, its actual truth is marred by secondary actions, which prevent an accuracy greater than one part in 1,000. The volt depends on this, and therefore no measurement of current or of electromotive force can be relied on beyond one part in 1,000.

This question of the limit of accuracy of measurement of the actual and relative values of quantities is one which is frequently ignored. There is no such thing as the knowledge of the absolute value of any quantity. We can only know its value to a certain approximation, and this should be definitely expressed by the figures used, and it is useless to try to push this limit beyond the limit of the standards. Sometimes this standard is very imperfectly known, e. g., the value of the unit of heat is not reliable beyond one part in 400 at the most.

Frequently, however, the number of figures intended to denote a value are not justified by the degree of accuracy of the experiments by which it has been determined. The accuracy of a result is the accuracy of the weakest part, like the strength of a chain. The determination of other values involved to a much greater degree of accuracy is mere waste of time, while the quoting of them is deceptive. How often does one see a reading on a galvanometer consisting of two figures expanded by a long division or by the use of seven figure logarithm tables into a result of some five figures. The last three figures are purely gratuitous, and are quite unreliable.

The same fictitious accuracy is often seen in the design of measuring instruments. It is not infrequently the custom to design voltmeters with an expanded scale over a short range, and to advertise accuracy of scale reading to $\frac{1}{10}$ volt at 100 volts, that is, an accuracy of one part in 1,000. This is merely the seven figure logarithm over again, it being useless to magnify the scale beyond the size where the errors due to friction and the effects of temperature and residual magnetism become appreciable distances on the scale.

Under this head I feel compelled to mention an instrument for which I have a great admiration, and which has recently been eulogized before another society. I refer to the potentiometer. The delicacy is very great, almost comparable with that of the Carey-Foster method of comparing resistances, the Whitworth measurement of length, and the measurement of mass by the chemical balance, and for comparative values taken at short intervals of time it is unrivalled in its own line. But for actual values it is like using a delicate balance with a set of letter weights, or a Whitworth machine with a common foot rule as standard. A delicate method of comparison is useless beyond the point of reliability of the standard, which in this case is one part in 1,000. Even this is by no means easy to attain. Such an accuracy on the silver voltmeter requires great practice and very careful work, while the Clarke cell requires just as careful handling. It is not an immutable thing like a gramme weight of platinum, crystal, or gilt brass, but it is generally used with as little regard for its peculiarities. Notwithstanding its large temperature variation, the worker ignores its previous condition, and with a light heart applies a thermometer and a table of corrections, as if the E. M. F. had some direct connection with the mercury in the thermometer instead of being related only by the very indirect and slow-acting conditions of solution or deposition of sulphate of zinc.

The essence of applied science is emphatically the power of measurement for the purpose of checking the accuracy of previously calculated or estimated designs and for investigating the properties of materials used, in order to obtain data for future work. We may divide experimental research into three classes. 1st, qualitative observation of the occurrence or non-occurrence of some phenomenon; 2d, comparative quantitative observation of the variations of a phenomenon with change of conditions; 3d, absolute quantitative determination of the value of a phenomenon. The first two classes include the bulk of scientific research, for the absolute value is frequently of minor importance and depends on the particular piece of matter used, while the changes in value are common to a large class of bodies and indicate physical laws. The determination of the absolute value of an important physical quantity to a high degree of accuracy is a matter of great difficulty and forms the object of some of the most laborious investigations. To a large extent, however, the engineer can only deal in absolute values, because he immediately wishes to compare the result with that given by some other arrangement of his machinery. With him the all-important question is by what method a certain result can be most economically obtained, using the word "economy" in its widest meaning. For instance, a physicist or chemist may be interested in the various processes in the production of mechanical energy by the consumption of coal. The effect of varying the supply of air to the fuel, the wetness of the steam, the result of altering the initial pressure, the expansion and condenser pressure, the surface condensation under different conditions and many other points are all problems of scientific interest and may be dealt with separately. But the engineer must take all of these points into consideration at once, make the best compromise that he can between conflicting requirements, and sternly require of each improvement that the resulting increase in efficiency shall not be swallowed up by the increase in cost of plant and labor. Finally he must compare the total result with that given by some other means of obtaining mechanical energy in order to make a final decision.

For this reason, therefore, the method of investigating engineering problems must to a certain extent differ from the purely scientific treatment. The scientist narrows the conditions of his problem and simplifies the phenomena until the result, though highly artificial, illustrates the action of a single law. For the engineer, on the other hand, it often seems difficult to avoid the combination of all the variables, and in consequence he hardly differentiates their individual effects, and does not always discern which of them are essential and where the point of weakness lies. That truly English panacea, a substantial factor of safety, is made to take the place of more precise knowledge, the additions being occasionally put in quite unnecessary places.

On the other hand, much time and energy are expended, especially by mathematicians, in elaborating hypothetical problems, the conditions being chosen to suit their method of analysis, and the desirability and even the possibility of realizing those conditions being disregarded. This has been especially the case with alternating current problems. It seems a field so evidently made for mathematical treatment of an interesting nature, and so impossible to attack by any less rigid method of reasoning, that one almost feels called upon to give up the use of such an unreasonable material as soft iron, and even to abjure the use of most dielectrics, in order to rest in the security of an analytical demonstration.

It is necessary therefore to beware of the spurious accuracy of the page full of mathematics just as much as the seven figure logarithms. It has been pointed out, but the caution is frequently ignored, that mathematics is like a flour mill. The quality of the flour turned out is not better than that of the corn put in, and if not ground with due care and precaution may be a good deal worse. If the data are unreliable, or if the proportion dealt with cannot be expressed as a mathematical function, the results can have but a very limited application. Examples of this are often met with in calculations of cost and efficiency, where wonderful coefficients and constants stand for interest, depreciation, labor, superintendence, load factors, commercial efficiencies, plant efficiencies and other quantities and values, which are familiar enough to the engineer, but of which the laws are only imperfectly known.

It must not be thought, however, that I wish to disparage scientific principles and methods in electrical or in any other branch of engineering. There is no other safe foundation, especially in electrical work. The agents and phenomena are so intangible and unusual that the old-time faculty of experienced intuition, by the light of which an engineer was supposed largely to work, is exceedingly difficult to cultivate and frequently leads the possessor startlingly astray. What we want is more appreciation of actual working conditions in our mathematics and a more scientific direction and greater breadth of applicability in our engineering experiments. This latter need is the weakest part of all engineering science and the most important. An isolated case of a machine which works well contributes little to knowledge. A similar case of one which works badly gives not much more information. But it is perhaps unreasonable to expect manufacturers to build a series of experimental machines, each differing slightly in one particular, to settle the absolutely best conditions, or if this is done, as has been sometimes the case, the world at large can hardly expect to have the benefit of the work presented to it. Moreover, workshops are not the best places for research, nor is engineering experimental work a pastime at which untrained players can get results of any value. It is easy to obtain some sort of result in experimental work; it is so difficult to attribute it to its true cause and to eliminate all side issues. From the nature of the case secondary actions crowd around the main point and but few men can have both time and ability for elucidating them. Much good work has been done in the factory, but, as stated above, it is generally of an unobtrusive nature. Much has also been done in physical and technical laboratories, and I venture to think that manufacturers, central station and consulting engineers will find that a greater amount of sympathy with these institutions and mutual assistance and collaboration with them will result in true economy to themselves and will greatly help to establish a firm scientific foundation for electrical engineering.

The value of a light attached to a buoy flung into the sea to save a life, says an English magazine, has been well proved by the Holmes chemical torch, which ignites when the water reaches the composition. A German electrician has recently brought out a new buoy lighted by an electric lamp of sixteen candle-power enclosed in bullseye lenses and protected by a cage of wire. The current is supplied by an accumulator of the "solid" or celluloid type forming part of the buoy and charged so as to maintain the light for no fewer than six hours. As the light can be seen for 2,000 yards in any direction, the buoy will be a useful aid at sea.

NOTES ON RECENT ELECTRICAL ENGINEERING DEVELOPMENTS IN FRANCE AND ENGLAND[*]—III.

DISCUSSION.—(*Continued.*)

Mr. M. N. Forney—There are some things contained in this paper in relation to the Heilmann locomotive which interest me very much. I might say in the beginning that I know very little about electricity, but I know perhaps something about locomotives. There are several statements in this paper which are urged in favor of the locomotive and which could hardly go entirely to the credit of the electric locomotive. For example, it is said that the Heilmann locomotive rests upon sixteen wheels, and on page 144 that Mr. Heilmann "is able to carry a larger boiler and hence does not have to crowd it to such a wasteful point." Now it is not quite clear to me why you are not able on an ordinary locomotive to carry as large a boiler on sixteen wheels as on an electric locomotive. An ordinary locomotive and tender is always carried on sixteen wheels although the weights are not exactly the same, the Heilmann locomotive being heavier. The electric locomotive must, in addition to the engine and boiler and other appliances, carry its electric machinery besides. So that it appears that the old steam locomotive has something to say for its side.

There is another statement on page 144 in which it is said that "probably at least one-third of the cost of maintenance of the roadbed and the locomotives for high speed service could be traced directly to this destructive hammer blow and side thrust." Now it would be interesting to know on what sort of evidence that statement is based. I confess that after being a student of railroad matters for a good while I have never heard that so large a proportion of the repairs of roadbed can be assigned to any such cause as that. It is very true that experiments have been made showing that some very destructive action occurs in locomotives in which there is an excessive amount of counterbalance. A good many cases have been quoted in which, it is said, that rails have been bent, and the experiments made at Purdue University also show that at very high speeds, with excessive counterbalance, the wheels raised up entirely clear of the rails. But it is also shown by the same experiments that there are substantially no injurious results when the locomotive is counterbalanced in a reasonable way.

On page 146 it is said that the cost of the Heilmann locomotive is $30,000. Now an ordinary passenger locomotive of the largest size can be obtained for about $10,000 to $12,000 at the present time. There would therefore be a difference of about $18,000 to $20,000 in favor of the present steam locomotive. I think hardly any prudent business man would venture to make an investment of that kind without allowing 10 per cent. on the extra cost to cover the interest and cost of replacing it. That would give you an excess of interest account for the Heilmann locomotive of $1,800 to $2,000. You may take it as a rough statement that a locomotive will burn per year about $2,500 worth of coal. I am taking a rough average through the country. As you have $1,800 to $2,000 excess of interest for the Heilmann locomotive, you would have to do the same amount of work with $500 to $700 worth of coal with the Heilmann locomotive that we are now doing with $2,500 worth on the steam locomotive.

I am entirely ignorant of the appliances used on the Heilmann locomotive, and there may be features there which would give a very great advantage in locomotive practice. But from the showing that is presented here it seems to me that there is a good deal still to be said in favor of the steam locomotive.

Dr. Cary T. Hutchinson—It may be interesting to give some information about a large electric locomotive which has just been finished by the Baldwin Locomotive Works. This locomotive has eight drivers connected rigidly by side bars, making a wheel base of 16 feet, the length over all being about 30 feet. The weight is 133,000 pounds uniformly distributed on the eight drivers, giving 16,700 pounds to each driver. There are four motors, one on each axle, the motors being built directly on the axle without springs of any kind between the armature and the axles.

The machine has a capacity, on a four hour test, of 1,000 H.P. at a speed of 35 miles per hour. The regulation is the series parallel. The motor being: 1st, all in series; 2d, two series by two in parallel; 3d, all four in parallel. There is also a resistance intended for use on first position in starting. The lowest speed, without resistance, is about seven miles per hour.

A test recently made at the Baldwin Locomotive Works showed an efficiency of more than 92 per cent. when operating 1,000 H. P.

The motors are designed so that they will work without sparking with full current in the armature at one half normal field strength. That is to say, they will operate at any speed from 35 miles per hour up to about 65 miles per hour at the same power, the drawbar pull varying inversely as the speed. At speeds below 35 miles per hour the drawbar pull is constant, the power, therefore, being directly proportional to the speed.

The smoothness and absence of vibration was very noticeable in the test referred to. The entire machine was supported on four jacks without bracings; when running with full torque there was scarcely any shaking.

Mr. W. L. Bliss—On page 144 Mr. Leonard says: "But regardless of an abundant supply of steam from the boiler, we find ourselves greatly limited in power for steam locomotive practice at high speed, because of the wire drawing of the steam and difficulty of properly exhausting when we run our locomotive at its highest speed."

On page 145 he states further: "The engine in practice," which I suppose is the engine driving the dynamo, "is varied in speed from 60 to 500 revolutions, and the strength of the generator field from zero to its maximum strength." I have made a rough estimate here as to what that speed represented. In the first place, on page 144, Mr. Leonard complains that the high speed of the steam locomotive causes wire-drawing of and difficulty in exhausting the steam, whereas these troubles are obviated in the Heilmann locomotive. He assumes, however, that in the Heilmann locomotive the prime mover runs up as high as 500 revolutions. I have made a little calculation on the margin. I remember that the Empire State locomotive No. 999 has 86 inch driving wheels. That would be a circumference of 22.2 feet. At 60 miles per hour the drivers would make 236 revs. per minute, which is less than one-half as fast as the Heilmann locomotive would be going to make the same speed on the assumption that the latter makes 60 miles per hour at 500 revolutions. If we go to 120 miles per hour (or 112 per hour, which is the record of the Empire State locomotive), we should not be running the same quite as fast as the Heilmann prime mover, so that I should think there would be no more difficulty with high piston speed and wire drawing in the Empire State than in the Heilmann locomotive, for the engines are evidently operating at nearly the same speed.

Mr. Richard Fleming—In connection with the cost per kilowatt of the European dynamos, I would like to ask Mr. Leonard why the cost of the dynamos is higher there than here. Are they more liberally proportioned, or is the workmanship so much superior to ours that they have to charge more for them? Why is it? I would also like to state in connection with the use of the three-wire system on alternating lines that in the winter of 1890-91 I built a small plant in the far West, in Washington, where I transformed from 1,000 volts in the primary to 208 volts in the secondary, using the Edison three-wire system. They were compelled to change from the regular continuous current three-wire system to the alternating and used the same wire. We used the standard Thomson-Houston transformer with primary windings in multiple and secondary windings in series.

Mr. Joseph Sachs—The remarks made by the previous speaker bring to my mind a similar instance of a small plant installed in 1889 in this city in the Lenox Lyceum, which was wired to be operated by the Edison three-wire system. Afterwards a small alternating plant was installed at the station of the New York Steam Company adjacent and two Westinghouse machines were put in, operated at 1,000 volts and the secondaries of the transformers operated at 50, were so employed as to operate all the three-wire Edison system in exactly the ordinary three-wire fashion. This was quite an original feature at the time, as not very much of this kind of work had been done at that date. I would also like to make a note of the line on page 135: "What is needed is a generator of electricity directly driven by, or preferably constituting a part of the revolving disk, and here is food for considerable thought." I wish to say that several friends of mine at the present time are at work on such a device, and it has often seemed to me that it would be feasible to devise some form of unipolar or very simple commutating machine which could be coupled to the shaft of a very high speed turbine, and although the element of friction, which is really the principal thing to be overcome in a case of that kind, is very severe, I believe that such a device can be operated. A self-contained dynamo and engine of that kind would certainly be the acme of simplicity and cheapness. Prof. Crocker may perhaps be able to give us some figures in regard to the coupling of unipolar dynamos at these speeds to turbines.

---

[*] H. Ward Leonard's paper read at a meeting of the A. I. E. E., February 27.

Prof. Crocker--I hardly think a subject of that magnitude can be considered a proper part of the discussion of a general paper of this kind, but I believe that some such device as you suggest can be made practicable. But it is such a large subject that it would require an evening for itself.

The President—Before calling on Mr. Leonard to close the discussion I wish to voice what I am sure are the sentiments of this meeting, by saying how much we have enjoyed this able paper, and how the value of the paper is evidenced by the very general discussion it has called forth.

I would like to say on my own part that I do not share Mr. Leonard's fear as to the evil effects of gigantic corporations, although I do not desire to be regarded as speaking unqualifiedly in favor of them. I do not think, however, that the statement made, that the practical development of engineering improvements is opposed by the gigantic corporations in the electric field is warranted by the facts. On the contrary, if I have read aright the history of progress of electrical engineering science in this country, it has not been in spite of the gigantic corporations but by reason of such corporations that such progress has been made. If here and there an inventor does not succeed in getting his particular system adopted by a corporation, he may, perhaps, naturally feel that such corporation stands in the way of its introduction. But we should not lose sight of the fact that these corporations are in the field for business and will be apt to buy anything that has real commercial value. It might be true, if all the corporations were represented by a single body, that such gigantic monopoly might absolutely discard anything of value. But when we remember that there are several, perhaps three or four or half a dozen, it is evident that a live company or corporation cannot fail to see the advantage of anything which possesses true merit.

I have shared the general surprise of probably some of you here in learning that the Heilmann locomotive, a locomotive that probably carries a central station with it, can show such favorable figures as it appears to regarding economy. It is a matter of great surprise to me, and I am rather disposed to think that a great deal of the supposed advantages possessed by the Heilmann locomotive will, in fact, be found to consist in an improvement of mechanical locomotive practice. If, however, it be true, what we have claimed for the great flexibility of electricity as a means of long distance transmission of power, will, it seems to me, to a very great extent be lost. It is a very interesting question, however, and I shall look to the solution of it with considerable interest. Of course, I recognize the question of speed as being in favor of the electric locomotive.

I will only say, in conclusion, as to Mr. Leonard's fear lest all able consulting engineers should be controlled by these gigantic monopolies, that he affords a notable instance of an able one who, I believe, has not yet been so controlled.

(To be continued.)

The Hogan Boiler Company.

On Tuesday, April 9, there will be a public exhibition of the Hogan boiler at the works of the company in Middletown, N. Y.

Trains leave foot of Chambers street at 9:15 and 10:30 A. M., returning to New York early in the evening.

The Trolley's Onward March.

It is announced that the New York Central Railway Company will equip the branch from Buffalo to Niagara Falls with the trolley system and that many of the contracts therefor will be signed this week.

This move is probably due to the fact that another company has planned for a new electric line between those points.

London Notes.

(From our London Correspondent.)

Transmission of Power by Electricity.

At the ordinary meeting of the Institution of Civil Engineers on March 5 two papers, dealing with the transmission of power by electricity, were read.

The first, on "Electrical Haulage at Earnock Colliery," by Mr. Robert Robertson, B. Sc., M. Inst. C. E., opened with an account of the general features of the colliery and of those of its seams into which electrical haulage had been introduced. The arrangements of the shafts and the capacities of the cage and coal-hutches were such that the daily output amounted to 1,200 tons. Details were given of the lengths and gradients of the main haulage roads in the Ell and Main coal seams and of the two steam hauling engines operating those roads on the main and tail and endless rope systems respectively. Electrical hauling engines had been introduced to drive endless ropes and to replace horse traction between the main haulage roads and the working faces.

The electrical generating plant comprised a dynamo for supplying power to the electrical hauling engines, capable at a speed of 620 revolutions per minute of an output of 100 amperes at 490 volts. It was driven from a shaft coupled direct to two single-acting Westinghouse engines, having cylinders 13½ inches in diameter, with a length of stroke of 12 inches, and developing together, when running at their normal speed of 350 revolutions per minute, 122 H. P. with a steam pressure of 50 lbs. per square inch. The electrical circuits were metallic throughout and the conductors were highly insulated, being sheathed also in iron pipes in the shaft and supported upon insulators in the workings.

The two electrical hauling engines, of which the main features were similar, were next described and illustrated. The motor of the engine in the Ell coal seam, when running at a speed of 770 revolutions per minute, developed 35 H. P. with a current of 76 amperes at a pressure of 400 volts. It was geared, through an intermediate shaft, to two pulleys with Hurd clips, each provided with a friction clutch and brake, by which the cables were driven at a speed of three miles per hour. The two cables were of stranded steel wire ¾ inch in diameter, and after passing over balance wheels placed in recesses near the engines operated circuits of 2,160 yards and 1,020 yards in length respectively. The cables were supported at intervals of about 30 feet along the roads by rollers 4½ inches in diameter, and at the corners were passed over wheels 5 feet in diameter, mounted upon vertical axes below the level of the rails. The gradients were so arranged at the corners that the trains of trucks could there travel without aid from the ropes. In the main coal seam a cable operated similarly a circuit 1,580 yards in length. The cables were driven continuously at a uniform speed, and the coal-hutches were attached to or detached from them by a Smallman clip.

The efficiency of the plant as compared with the horse traction which it had replaced was then considered. The electrical haulage system in the Ell coal seam was capable of a daily output of 400 tons. The daily output by horse traction had been 180 tons, and to increase this to 400 tons thirty or forty horses would have been required, a number which could not have been employed in the available space without confusion. The daily output of the electrical haulage system in the Main coal seam, which was not yet working at its full capacity, was between 150 and 200 tons.

The yearly working expenses of the two systems were compared, upon the results of one and a half years' working, and was found to be £4,180 and £1,990 by horse traction and by electrical haulage respectively, showing that an annual saving of £2,140 had been effected by the latter. The total cost of the electrical installation had been £3,500.

In the second paper—"Water Power Applied by Electricity to Gold Dredging"—by Robert Hay, M. Inst. C. E., an account was given of a plant which had been erected in New Zealand to utilize water power for generating electricity to be transmitted to motors operating a dredge in different portions of a distant river. The author pointed out that the transmission of water power by electricity, in well watered countries like New Zealand, rendered available deposits of gold in districts in which the scarcity of fuel would not permit of their being worked by other means. The plant described had been constructed for gold dredging in the River Shotover, the course of which was for the most part in rocky gorges through rugged country, accessible only by tracks cut down the leading spurs and gullies.

The source of the water power and the method of its application were then described and illustrated by a longitudinal section of the pipe line. The water was obtained at a creek one and a half miles distant from the dredging ground, and was brought by a race cut in the side of the hill, or, in places where the ground was not suitable, in a timber flume to a pressure tank at a level of 524 feet above the pipes at the generator house. From this tank to the Pelton wheel the water was carried in rolled steel pipes constructed in lengths of 19 feet 6 inches, bolted together by wrought-iron flanges riveted to the pipes.

The prime mover of the generating plant was a 4-foot Pelton reaction water wheel, upon the buckets of which the water, from a nozzle 1⅜ inches in diameter, impinged at a pressure of 228 lbs. per square inch. This wheel drove two series wound dynamos working at a normal speed of 700 revolutions per minute, each developing a current of 40 amperes at an electromotive force of 650 volts, or together nearly 70 H. P. The dynamos were coupled in series, and to guard against damage from abnormal increase of current a regulator was so arranged as to throw into the circuit an artificial load in case of the current becoming from any cause 3 amperes greater or less than its normal amount. The conductors, of a length of two miles, were of No. 4 S. W. G. bare copper wire, and were supported upon insulators carried by cross-arms upon old 40-lb. rails.

The current was conducted to two motors in the dredge, one for driving a centrifugal pump and the other for operating the buckets, winches and revolving cylinder. These two machines were duplicates of the dynamos and were coupled in series so that when the bucket motor was switched off the pump motor absorbed the surplus power by increasing the speed of the pump and causing it to throw more water.

The dredge was constructed for the most part of steel and was capable, when operating at a depth of 20 feet, of an output of 90 cubic yards per hour. The dredgings were delivered, through a revolving screen for separating the stones and coarser material, upon baize tables set at an inclination of 1 in 12. Two 10 ampere arc lamps lighted the dredge at night and were joined in multiple series with the motors, with suitable arrangements for their control. A table of particulars of the efficiencies of various parts of the plant was given. The cost of the installation and the weekly working expenses, £7,000 and £35 respectively, were also tabulated.

Cards are out for a reception and exhibition at the station of the Brooklyn Edison Company tonight (April 3).

A Move in the Right Direction.

The first steps have been taken to put feed water heaters upon a definite rating, and it is to be hoped that these steps will lead to reforms which every steam user knows are much needed. Feed water heaters, like boilers, have been rated in terms of horse-power, which for apparatus of this kind, as every one knows, have absolutely no meaning unless further data are specified. For instance, a boiler of a given size may with equal propriety be rated as 20 H. P., or 40 or 10, and unless the conditions under which it is operated are specified, none of these ratings means anything, simply from the fact that the boiler does not do any work at all and therefore the term as applied to it is fallacious. So with feed water heaters. If, however, in describing a boiler the grate area and heating area are given, the data are at hand for calculating the performance under any given conditions, and boilers are thus now so designated. The same method of rating of feed water heaters would seem to commend itself, and we are glad that the subject has been taken up by such responsible people as indicated by the following :

Astor House, New York, Jan. 26, 1895.

We, certain manufacturers of closed feed water heaters, in convention assembled, declaring—

That a better understanding among ourselves and also between each of us and our customers in the matter of rating of feed water heaters is much to be desired, do hereby resolve

That we believe that the only proper rating for feed water heaters is one which is based upon the square feet of heating surface contained in the heater. For the purpose of giving practical shape to this belief we do further resolve

That we hereby agree that for the future we will in each and every case in which we are called upon to make prices upon heaters, state the exact number of square feet of surface which we are offering : to give further effect to this action we resolve

That we will in each and every case state without reservation, both in our printed catalogues and in our specifications, the diameter of the tubes, the number of the tubes, the number of lineal feet thereof and the total square feet of heating surface in each heater offered.

Resolved further, that the secretary be requested to transmit a copy of these resolutions to every manufacturer of closed heaters in the United States.

And we hereby agree to live up to the spirit and the letter of the foregoing and to bind ourselves so to do by our signatures affixed below.

Resolved finally that the secretary be requested to invite all closed heater manufacturers of the United States to join this Association and to subscribe to the foregoing resolutions.

(Signed) The Taunton Locomotive Mfg. Company (makers of the Wainwright Feed Water Heater), Benj. F. Kelley & Son (makers of the Berryman Feed Water Heater), Wm. Baragwanath & Son (makers of the Baragwanath Feed Water Heater), The Goubert Mfg. Company (makers of the Goubert Feed Water Heater), The National Pipe Bending Company (makers of the National Feed Water Heater), Robt. Wetherill & Co. (makers of the Wetherill Feed Water Heater), Keystone Engine and Machine Works (makers of the Keystone Feed Water Heater).

FRANK A. THAYER, Secretary.
14 Church street, New York.

The Cincinnati and Dayton Electric Line.

The project of building an electric line from Cincinnati to Dayton via Middletown and Hamilton appears to be on a sound footing. The directors of the company are: L. C. Weir, president Adams Express Company; S. M. Felton, president Cincinnati Southern Railroad; W. A. Goodman, president National Lafayette Bank; A. Hickenlooper, president Cincinnati Gas Light and Coke Company; H. H. Hoffman, president Cincinnati Tobacco Company; O. C. Barber, president Diamond Match Company; George B. Cox, president Hauss Bro. Manufacturing Company; O. B. Brown, attorney-at-law, and H. B. Morehead, financial agent.

Mr. Hickenlooper says:

Our company will build a double track between Avondale and Dayton, going due north to Glendale, and from there northwest to Hamilton, and thence on to Dayton. Next week we will probably fix the date for beginning the work of construction. I do not know whether we will operate with a single or double trolley system. Can we compete with the railroads? Well, I rather think so. The line is so near straight that we will have an advantage in the matter of miles, and expect to make very nearly as good time as the railroads. But it is in the fare that we will be able to do most. We will carry people for about one-third the fare charged by the railroads.

BOOK REVIEW.

PROCEEDINGS OF THE INTERNATIONAL ELECTRICAL CONGRESS HELD IN THE CITY OF CHICAGO, AUGUST 21st TO 25th, 1893. Cloth. 8vo, 488 pp. $3.00. Published by the American Institute of Electrical Engineers, New York.

This book is the official record of the proceedings of the Congress and will be valued by all who wish to preserve in convenient form the many valuable and interesting papers presented at that time, as well as the decisions of the Chamber of Deputies which settled, for the time being at least, so many of the points at issue up to that time. Aside from its value as a work of reference, a book of this kind loses much of its value by such a long delay in issue, but in this case at least the delay seems to have been unavoidable by reason of the widely scattered residences of those whose co-operation was essential to its success. It were far better, however, that the publication should be late and *accurate* than that it should be earlier and inaccurate, and we believe that the delay has been warranted, in a measure at least, by the apparent extreme care and fidelity with which everything connected with the Congress has been collected.

There has been one very regretable omission, however, viz., that of Prof. Ayrton's elaborate paper on the Arc Lamp. The manuscript of this, through a most inexcusable and unfortunate piece of carelessness, was destroyed, and we are ashamed to say that the carelessness was that of an American.

While the present price of the book is $3.00, we are notified that this is subject to advance, doubtless in anticipation of libel suits on the part of some of the members of the Chamber of Deputies whose pictures are given in the frontispiece. This latter is simply awful. What will Mascart's descendants say when they see his picture? Rowland is all right if he wants to look that way, but we fancy that even Prof. Forbes would not be so unkind as to send him a valentine like this. Hospitalier looks as though he was saying "Oh mamma, see me now," and Carhart's picture reminds one of the picture entitled "Who Said Rats?" Preece resembles a Methodist clergyman of the Pike County type, or the Rev. Stiggins about to weep over the cruel jibes of Weller, Sr. Elihu Thomson—well the story is told of a good old Harvard professor who in his absent-mindedness was walking with one foot in the gutter and the other on the curbstone, and wondered what made him so lame. Thomson looks as though he were doing the same thing, but with his hand upon his heart was devoutly hoping he wouldn't be that way always. Mendenhall has a pose and expression recalling Ajax defying the lightning as he stands there with bared breast looking off into space of n dimensions. We fancy Ajax never assumed such a tantalizing pose, however—either this or the lightning was unusually good-natured. Leduc looks like Weaver of the *Electrical World*, but that is the fault of the camera, and he is not to blame. We remember seeing a picture once entitled "A Black Cat in a Dark Cellar." It was a nocturne in which the cat was invisible by reason of its surroundings. Voit's picture reminds us of this—he is invisible by reason of his surroundings.

LEGAL NOTES.

N. Y. Insulated Wire Co. vs. Westinghouse Electric Co.

Suit was brought last week in the Supreme Court by the New York Insulated Wire Company against the Westinghouse Electric Manufacturing Company to recover $35,411.51 alleged to be due as a balance for the wiring work on the World's Fair Building, and an attachment was secured against the property of the latter company in this State.

Later the attachment was set aside by Justice Beekman upon the claim of the Westinghouse officials that they have a defence to the action, and that the procuring of an attachment against the property was a spiteful attempt on the part of the Insulated Wire Company to do the Westinghouse Company an injury.

In the suit of the Citizens' Electric Light Company against the city of Jacksonville, Fla., involving the question of commercial lighting, Judge Call decided that the city had a legal right to put in an electric light plant and to furnish commercial lights to its inhabitants.

The Montgomery County (Pa.) Railway Company, operating a trolley line, sued the Pennsylvania Railroad Company to secure the right of way at crossings along the route of its railway and gained a favorable decision in the lower court. The case was appealed and the Pennsylvania Supreme Court has reversed that decision, holding that the Street Railway Act gave no right of eminent domain, and that as the trolley lines are incorporated under that act they have no power to construct their roads where the taking of property is incident or necessary to it without the consent of the property owners. The decision injuriously affects $50,000,000 of capital invested in trolley lines over the State, and many of the long distance projected lines will have to be abandoned or compelled to confine themselves to highways until relief is secured from the Legislature.

Judge Green, of the U. S. Court at Trenton, N. J., has refused to grant the injunction sought by the American Graphophone Company restraining the Edison Phonograph Company from operating under the Edison patents. Similar suits were brought in New York, Ohio and other States. The decision of the United States Court at Trenton will, it is thought, govern the decisions in the other States.

Judge Wheeler has ordered Receiver C. S. Mersick, of the Ansonia Electric Company, of Ansonia, Conn., to use part of the money paid for the concern by Franklin Farrel for a 10 per cent. dividend for the creditors, the rest to go to the receiver. An additional 15 per cent. will be paid later.

Electric Snow.

The story of a most remarkable snow storm is told by Lieut. John P. Finley, one of the best-informed meteorologists in the United States, who encountered the storm in making an ascent of Pike's Peak. He says the storm could best be described as a "shower of cold fire." In reality it was so charged with electricity as to present a scene more easily imagined than described. At first the flakes only discharged their tiny lights on coming in contact with the hair of the mule on which the lieutenant was mounted. Presently they began coming thicker and faster, each flake emitting its spark as it sank into drifts of the snow or settled on the clothing of the lieutenant or the hair of the mule. As the storm increased in fury and the flakes became smaller each of the icy particles appeared as a trailing blaze of ghostly white light, and the noise produced by the constant electric explosions conveyed an impression of nature's power which Lieut. Finley will never forget. When the storm was at its height and each flake of snow was like a drop of fire, electric sparks were shaken in streams from the lieutenant's finger tips, as well as from his ears, beard and nose, and a wave of his arms was like the sweep of flaming sword blades through the air, every point of snow touched giving out its little snap and flash of light.—*New York Tribune.*

General News.

What is Going on in the Electrical World.

Monroe, Mich.—The council has passed an ordinance revoking the franchise of the Toledo, Monroe and Detroit Electric Railway Company.

Flushing, Mich.—At the late election it was voted by a large majority to bond the village in $20,000 for a waterworks and electric light plant.

Warsaw, Ill.—Wilcox & Son, of Oskaloosa, have bought the local electric light plant from E. B. Hillman & Co., of Peoria, who established the plant.

Bloomfield, N. J.—The 10 per cent. reduction in wages which took place at the Sprague Electric Elevator Works last fall has been restored to the men.

Pittsburg, Pa.—The contract for the construction of an electric railway from Pittsburg to Johnstown has been let by the Second Avenue Traction Company.

Trenton, N. J.—The bill authorizing cities of over 50,000 population to construct and maintain electric light plants has passed the House and is now before the Senate.

Mauston, Wis.—The Mauston Improvement Company, of which J. T. Heath is president, intends to put in electric lights and a telephone system here at an early day.

St. Paul, Minn.—Thomas Lowry, owner of the Selby Avenue cable line has decided to change that line to an electric and extend it to Minneapolis over the Marshall avenue bridge.

Oregon, Ill.—The officials of the Rock River Electric Railway have decided to go to work at once on the new road.—There is talk of building an electric road from Oregon to Amboy.

Gloversville. N. Y.—The route for the proposed trolley railroad from Gloversville to Broadalbin has been surveyed, and as sufficient funds have been raised there is no doubt of the road being built.

Fort Wayne, Ind.—Murray Hartnett has been appointed receiver for the Orr Bros.' Electric Manufacturing Company. The company was incorporated about a year ago with $10,000 capital.

Lancaster, Wis.—The Lancaster city council has granted to Edward Pollock an exclusive franchise for an electric light and power plant upon condition that it shall be in operation within six months.

Chatham, N. Y.—Bids will be received at the office of the city clerk until noon on the 8th day of April for lighting the streets of this village. Eighty-five incandescent lights or more, of 25 candle power, are required.

Guthrie, O. T.—The local electric light plant is now in the hands of J. Sam Brown, who has paid off the mortgages on the plant and will make improvements in the way of new machinery and give an all night service.

Herkimer, N. Y.—The application of the Mohawk, Herkimer and Ilion Railroad Company for a change of motive power from horses to electric trolley on their street line has been granted by the State Railroad Commissioners.

Peoria, Ill.—The Peoria General Electric Company has applied to the city council for permission to erect poles and string wires for the purpose of furnishing light, heat and power to the city and its inhabitants.

London, Ont.—The street railway company have secured permission to change the motive power of their road from horses to electricity. Henry A. Everett and E. W. Moore, of Cleveland, O., are the principal owners of the road

Stoughton, Mass.—The capital stock, $12,000, of the company that proposes to build an electric railway between Stoughton and Canton has been subscribed, a board of directors elected, and work on the line will begin as soon as practicable.

Medford, Wis.—Prominent business men and taxpayers have petitioned the council to order an election to get the public vote on the question of bonding the city in the sum of $5,000 for the purchase of an electric light plant to be owned and operated by the city.

Lockport, N. Y.—The council has granted a franchise for an electric street railroad in this city to C. A. Johnson, of New York. The city discontinues none of the pending actions against the old company until Johnson either fails to perform or complete his contract,

Oshkosh, Wis.—J. K. Tillotson of the Wisconsin Interurban Railway Company states that contracts have been let for twenty-six miles of rails to build the interurban line from Oshkosh to Kaukauna, besides fifteen miles of road to be built in the city of Oshkosh.

Wilmington, Del.—It is reported that all the funds needed for the West Chester and Wilmington Electric Railway are arranged for. The route is via Talleyville. As soon as the Legislature grants the charter there is nothing to prevent the commencement of work at each end.

Winona, Minn.—Receiver S. B. Livermore, of the Winona General Electric Company, has filed with the clerk of the United States Court a statement showing the financial standing of the company. The assets are $147,607.15 and the liabilities $504,610.42, which includes $270,000 of bonded indebtedness.

Frankton, Ind.—The town council has granted to Congressman elect Charles L. Henry a ninety-nine-year franchise of the streets for electric street railway purposes. Mr. Henry proposes to put in a line from Anderson to Elwood, passing through Frankton, and connecting at Anderson with the Indianapolis-Marion line.

Niagara Falls, N.Y.—The first great dynamo is set up in the power-house of the Cataract Company and is ready for operation, only awaiting the completion of the switchboard. The second dynamo is completed and after undergoing the requisite tests at the works of the Westinghouse Company at Pittsburg will be taken apart and shipped to the Falls.

Warren, O.—Col. D. M. Yeomans, of Kinsman, says there are prospects that the projectors of the electric road to connect that village with Chagrin Falls will consolidate with the Cleveland Suburban Electric road, which contemplates constructing lines to many northern Ohio towns, among them Chagrin Falls. The Kinsman-Chagrin Falls road will run through Bloomfield and Burton.

Milwaukee, Wis.—The *Sentinel* states that the number of men engaged in electrical pursuits in this city reaches into the thousands, that electricity is a factor in nearly every branch of business, and that millions of dollars are invested in electrical enterprises here. Over 50,000 incandescent lights and a proportionate number of arc lights enable the inhabitants to get around and see all there is to be seen after nightfall.

Athens, Ga.—The charter of the Tallesee Shoals Electric Company is being prepared. The capital stock of the company will be $50,000, with the privilege of increasing it largely. The enterprise will develop fully 1,200 H. P., which will be furnished cheaply to the manufacturing interests here. The Tallesee shoals are eight miles from Athens, and are one of the best water powers in the State.

Atlantic, City, N. J.—It is reported here that a syndicate of New York and Atlantic City capitalists have formed a company, which is capitalized at $4.000,000, to build an electric railway from New York to this city. If the scheme proposed goes through, the road will be in operation next summer. It is understood to be the same company which is building electric roads in and about Baltimore and Washington, and is now extending them northward to Philadelphia.

Seneca Falls, N. Y.—The Seneca Falls and Cayuga Lake Railroad, including the roadway from Ovid street to Cayuga Lake park, and all the property and rights of way of the company, will be sold here by the sheriff on the 18th inst. —It is understood that the electric railroad companies between Geneva and Seneca Falls have been consolidated under the name of the Geneva, Waterloo, Seneca Falls and Cayuga Lake Traction Company.

Chattanooga, Tenn.—Henry S. Ewing, special commissioner, has filed a deed of the property and franchises of the Chattanooga Electric Light Company to the Chattanooga Light and Power Company, the consideration being $250,000; the latter company has filed a deed of trust to the Old Colony Trust Company as trustee to secure an issue of $300,000 in bonds of denominations of $1,000 each, payable in gold coin in thirty years, and bearing 6 per cent. interest per annum.

Rochester, N. Y.—The Rochester. Charlotte and Manitou Railroad Company is the name of the company organized to take the place of the Grand View Beach Railroad Company, which went into the hands of a receiver last fall. The capital stock of the new company is $100,000. The directors of the company are: Michael Doyle. Louis Werfield, Charles W. Briggs, Valentine Fleckenstein, Otis H. Robinson, Emmett H. Craig, Martin Beatties, George L. Brown and Jacob Odenbach.

Logansport, Ind.—The Logansport city council has revoked the right of the Jenney Electric Light Company and the Logansport Electric Light and Power Company to furnish electricity to private consumers. The former has operated here for ten years under a contract which recently expired, while the latter exists under a special ordinance which the Supreme Court is said to have declared illegal. Both companies are ordered to remove all poles and wires from the streets within ninety days.

Sedalia, Mo.—A convention of superintendents of water, gas and electric light plants in Missouri was held here recently to perfect a permanent organization in the interest of the three branches of business. Nearly all of the plants in the State were represented. The organization, to be known as the Missouri Water, Gas and Electric Association, was perfected by the election of the following officers: President, W. E. Walton, Butler; vice-president, James A. Montgomery, Sedalia; secretary, C. F. Strohm, Nevada; treasurer, R. D. Wirt, Independence.

Lake Charles, La.—The town council recently referred the application of the embryonic Electric Railway, Heating and Telephone Company for a charter to a committee which is noted for hostility to new enterprises. When this action became known there was a general feeling of disappointment, and one irate citizen was heard to remark: "The people want improved methods of light, heat, communication and travel, and the fear that the electric cars may frighten a grass-fed pony or startle some cow into swallowing her cud will not deter them from demanding it."

Brooklyn, N. Y.—Electric lights are now in successful operation on the Bridge cars. Current is supplied by means of an ordinary trolley pole which is automatically reversed at either terminus. There are ten 16 C P. incandescent lights to each car, or 480 in all, 48 cars being the maximum number used at present.—An ordinance limiting the speed of trolley cars in the city streets to eight miles an hour has been adopted by the board of aldermen.—The specifications for the new lighting contract were published in the city papers of the 26th ult.

Louisville, Ky.—The Pennsylvania Railroad Company will soon test electricity as a motive power on the local accommodation trains running on their road between Louisville and New Albany. If the test proves successful electricity will likely be introduced for running accommodation trains on other parts of the system.—The Louisville Railway Company is transforming its cars on the Sixth street line into motor cars and trailers. Mules have heretofore furnished the motive power. Other lines in Louisville not yet electrically operated are to be changed in the near future.

Sacramento, Cal.—The *Bee* states that W. W. Felts, of this city, "has succeeded in developing a continuous electric light from a primary battery. He claims also that his battery is a perfect electrolyte and polarizer combined. Mr. Felts says that a continuous electric light from a battery has been heretofore considered almost impossible. Bunsen's system of primary battery is only certain for three hours at a time, whereas he claims that his battery will run for one month without cleaning or replenishing. He refuses to allow anybody to inspect his battery."

Buffalo, N. Y.—The New York Central Railroad Company intends to introduce the trolley system on its road between Buffalo and Niagara Falls as soon as the plans are ready. The power to operate the trains will be supplied by the Niagara Falls Power Company. Special cars of the observation pattern will be put on the road so as to give passengers a clear view of the scenery at the Falls. Sufficient power will be applied to give the cars the same rate of speed as at present, the fares will be reduced, and the comfort of passengers increased by the absence of cinders, smoke and other inconveniences of a steam road.

Atlanta, Ga.—The finance committee of the Exposition has approved Mr. H. M. Atkinson's plans for supplying electric lights and power. "The plans," says the *Constitution*, "contemplate the lighting of the Exposition grounds in the most brilliant manner. At night the park and buildings will be as bright as day. The Electrical Building and the flower garden, which are to be located inside the enclosure now used as a race track, will be particularly bright with lights. The Electrical Building will be a perfect blaze of glory and will shine to heaven."—The franchise for the electric line of the Atlanta Electric Railway Company in this city has been approved by the mayor, and the company has now the right to go ahead and build its line.

Detroit, Mich.—The Rapid Railway Company, the proposed electric line to run between Detroit and Mt. Clemens, has filed with the city clerk a chattel mortgage for $300,000 running to the Finance Company of Philadelphia. The company will hold the mortgage in trust for the holders of an issue of $300,000 worth of bonds. The mortgage covers the right of way in Hamtramck and Grosse Pointe townships, in Wayne County, and in the townships of Warren, Erin and Clinton, in Macomb County, franchises in Mt. Clemens and a traffic arrangement with the Detroit and Erin Plank Road Company on Gratiot avenue and the Citizens' Street Railway Company of Detroit. The bonds of the company are to run for twenty years at 5 per cent. Ex-Judge C. J. Reilly, as president, and Charles M. Swift, as secretary of the new company, signed the mortgage. Similar mortgages will be filed with the township treasurers of the several townships crossed.

Albany, N. Y.—Among the bills recently introduced in the Assembly was one appropriating $50,000 to establish a State board of gas and electric light commissioners, to be appointed by the Governor, the commissioners to have the right to annually inspect the business of gas and electric lighting companies.—A bill has been reported favorably from the Assembly Cities Committee which provides that at the next general election held in this State there shall be submitted to a vote of the duly qualified electors of each city of the first class the question of the ownership by such city of the franchises within its boundaries of all street railroads, whether operated on or below the surface of the street, and including also elevated railroads, and irrespective of the motive power which may be used on such railroads.—The bill authorizing the Canandaigua Electric Light Company to operate throughout the towns and villages in Ontario and Wayne counties has passed both branches of the Legislature and become a law.—The Senate committee on judiciary is giving consideration to a bill which is designed to convey in fee simple a mortgage on a good slice of the State to a company denominated the Maritime Canal Company of North America, which desires to be legally empowered to construct a $200,000,000 canal to unite the St. Lawrence and Hudson Rivers. The company, among other privileges too numerous to mention, desires to have a telephone and telegraph monopoly, the right to operate vessels of every sort and engage in a general real estate and transportation business. The most prominent men named in the bill are Henry G. Burleigh, Smith M. Weed, of New York State; "Sam" Allerton, the millionaire wheat manipulator of Chicago, and D. H Burnham, the builder of the World's Fair.

Telephone and Telegraph.

C. L. Downey has been authorized by an ordinance of council to maintain a system of telephones in Carbondale, Ill. It is understood that connection will be made with an exchange in Murphysboro.

The Harrison Telephone Construction Company for Kentucky and Tennessee has filed articles of incorporation at Louisville. The capital stock of the company is placed at $100,000. The business of the corporation is the construction and operation of telephones, and the principal office is to be in Louisville.

State control of telephone companies is the object of a bill now before the Massachusetts Legislature, and the Committee on Mercantile Affairs has given hearings to the advocates for and against the measure. The telephone companies are strongly opposed to it.

The trustees of Edgewater, S. I., have given the Automatic Telephone Company a franchise to establish its system in Edgewater.

A telephone company has been organized at La Crosse with local capital. The rates they propose are $30 a year for business telephones and $18 for residences.

The Wolf River Telephone Company of Orihula, Wis., recently incorporated, will put in a local exchange and construct a line from Orihula to Weyauwega via Fremont. The officers of the company are: Clemens Schmidt, president; Joseph Vogt, secretary, and A. L. Hutchinson, treasurer.

The citizens of Carbondale, Pa., are about to organize a company for the establishment of a telephone exchange. Parties who are prepared to furnish a complete and reliable system can obtain further information upon application to A. P. Trautwein, secretary of the Board of Trade.

The town of Calhoun, Ky., is now connected by metallic circuit with Evansville, Ind., and Nashville, Tenn., and will likely be in line with New York City the coming summer.

The Phœnix Telephone Company and the American Telephone and Telegraph Company have asked the council of Bayonne, N. J., for franchises to put in their telephone systems in that town. The company now operating through Bayonne is meeting much opposition because of its high rates.

The East Tennessee Telephone Company is making preparations to extend its lines from Chattanooga to Jasper, South Pittsburg and Bridgeport, and will shortly make connections by which Chattanooga will be able to communicate by the long-distance system with Knoxville and with Atlanta, Ga.

E. B. Monroe has applied for a franchise for a local telephone service at Warsaw, N. Y.

As a result of the telephone war at Frankfort, Ind., between the Central Union, the Strowger system and the Stethephone, the rates have been cut to a low figure. The Central Union makes the latest cut, and, besides, proposes to replace the old wire with the best quality of copper for long distance between Frankfort and Indianapolis and between Indianapolis and Lafayette.

A dispatch from Laporte, Ind., states that "the Elkhart Telephone Company, which will be a competitor of the Bell corporation, has been organized under the laws of Indiana. The board of directors includes R. B. Campbell, general manager Baltimore and Ohio Railroad Company, Baltimore, Md.; H. E. Bucklen, president Elkhart and Western Railroad Company, Chicago, Ill.; Charles Selden, superintendent of telegraph Baltimore and Ohio Railway, Baltimore; O. N. Lumert, Elkhart, Ind.; Joseph Claybaugh, Indianapolis, Ind.; W. F. Ranfiel, Frankfort, Ind. The company claims to have unlimited capital at its command."

The Indiana Harrison Telephone Company promises to begin the work of construction for its new system at Terre Haute in a few weeks. It expects to start into business with 600 subscribers.

The following statistics derived from the Bell Telephone Company's annual report are interesting. The report contains very full statistics of the business done for the ten years (1884-94). Instruments in the hands of licensees December 20, 1894, were 582,500 against 325,574 in 1884 and 566,491 in 1893; a gain for the past year of 16,015. This is a gain in increase of 2,244 over the increase of 1893, but 24,298 less than the gain in 1892, which was the banner year of the whole ten years. The year 1894 shows an increase less than any year since 1884 with the exception of 1893, the lowest previous record of increase being 23,478 in 1886. Miles of wire on poles increased the past year 17,332, and underground 27,610. Total miles of wire increased 43,194. The longest increases in miles underground have been: Boston, 2,841; Cleveland, 2,801; Detroit, 1,080; Jersey City, 1,720; Louisville, 2,080; Newark, N. J., 2,348; New York, 7,728; Washington, D. C., 1,083. The estimated number of exchange connections daily in the United States, made up from actual count in most of the exchanges, is 2,088,152, or a total per year of about 670,000,000. Not including the cost of current repairs and renewals, the companies operating under Bell licenses have expended during 1894, upon extensions of lines and apparatus, $4,138,000, and for buildings to accommodate their exchanges $411,000, making, with the amount reported last year, a total of investment in telephone property in the United States of $77,500,000.

The German Department of Telegraphs has been carrying on an investigation with a view to determining what effect the telephone wires in cities have on atmospheric electricity; i. e., whether the danger from lightning is increased or decreased by the presence of the miles of wires now necessary in cities in which the telephone is extensively used. The result of the investigation has been to show that the wires tend to weaken the severity of thunderstorms and to decrease the danger from lightning. From information received from 340 cities with telephone wires, and from 560 without them, it appears that the danger of damage by lightning in the two classes is as 1 to 4.6.

The Cumberland Telephone Company is extending its lines so as to connect Columbia, Tenn., with Lewisburg, Mooresville, Petersburg, Hampshire, Lipscomb and Frierson.

The Central Union Company has reduced its rates at Indianapolis to $60 a year and up for business houses within a mile radius and $42 for residences within that radius.

A charter has been granted by the Hustings Court at Staunton, Va., to the Mutual Telephone Company. The officers are R. S. Tuik, president; W. L. Oliver, vice president; Edgar M. Furkhouser, secretary and treasurer.

H. J. Edwards and associates have petitioned the common council of San Jose, Cal., for permission to establish a telephone system in that city. The company is composed of local capitalists.

The Bell Telephone Company, beset by competitors or competing projects in almost every town and city in the country, is rapidly reducing its rates, generally to a figure about two thirds of former rates, but when rivalry is pressing fifty per cent. or more is struck off.

At St. Joseph, Mich., the Gilliland Telephone Company of Chicago secured a franchise by offering to charge only $24 a year for the use of telephones in business houses. The Bell Company, which for years has been charging $48 a year, now announces a reduction to $18 for the same service.

The Strowger Automatic Telephone Company is making arrangements to establish its service in Milwaukee. The company has erected telephones in the Hotel Pfister and made connection with a 'phone in the Federal Building. The service does away with the necessity of operators or "hello-girls," the switchboard working automatically.

At Lockport, N. Y., the Bell Telephone Company has reduced its scheduled prices about ten per cent., and it is said this reduction will apply to all places in Western New York with the exception of Buffalo and Rochester.

The Laclede Electrical Company has 200 patrons pledged at Kokoma, Ind., and promises cheaper rates than the Bell Company, which has just reduced its charges 50 per cent.

The common council of Ithaca, Mich., has granted the Gratiot County Telephone Company a franchise to erect poles and string wires.

At a meeting of the projectors of the Home Telephone Company at Mobile, Ala., a few days ago, the capital of the company was fixed at $40,000, and the entire amount was subscribed. James K. Glennon, A. S. Lyons, P. J. Lyons, D. R. Burgess, A. H. Spira, W. H. Fitzpatrick, Henry Piser, Adam Glass and A. S. Benn were elected directors.

The ordinance granting a franchise to construct a telephone system in Philadelphia to the Drawbaugh Telephone Company failed of passage in the common council.

The Union Telephone Company, of Union, S. C., has been granted a charter. The president and treasurer is W. D. Arthur. Directors: G. H. Oetzel, W. E. Thompson, W. W. Nicholson and W. D. Arthur.

A telephone exchange is to be established at Tampa, Fla., by a new company. The present service there is unsatisfactory. Ocala, Fla., will have a complete telephone system in operation in a few days.

A home telephone company having been arranged for at Emporia, Kan., a few days ago, the Missouri and Kansas Company as soon as it heard the news made a cut of 25 per cent in its rates; nevertheless the organization of the new company was determined on and it guarantees a still lower rate.

Rome and Americus, Ga., will shortly be linked to Atlanta by telephone. The building of the line to Rome is the first step toward telephone connection with Chattanooga, and that means a step toward connecting Atlanta with Knoxville, Memphis, Cincinnati and ultimately Chicago and the Northwest.

The Wisconsin Telephone Company (Bell) has determined to immediately reduce its rates about 25 per cent. throughout the whole State, with the exception of Milwaukee.

A telephone company composed of business men has been organized in Sacramento

Cal., to compete with the Bell Company. Arrangements have been made with the California Telephone and Construction Company for the use of the Columbia instruments and system, of which that company is owner of the rights on the Pacific Coast.

The Direct Cable Company announces a reduction in its rates to South Africa, but those of our readers who have dealings with the Dark Continent will still be obliged to use greatly condensed phraseology in their dispatches if they wish to leave any bequests for the promotion of civilization among the heathen at that end of the line. The new rates per word are appended: Cape Colony and Griqualand West, Cape Town, $1.48; British South Africa, $1.58; Natal Durban, $1 48; all other offices, $1.52; Orange Free State, $1.52; South African Republic (Transvaal), $1.52; British Bechuanaland, $1 52; Bagamoyo, $1.52; Dar Es Salaam, $1 52; Mombassa, $1.48; Imperial British East Africa Company's offices, $1.58; Zanzibar, $1 48.

COMMERCIAL PARAGRAPHS.

The Metropolitan Electric Co. are finding very ready sales for their new Carbon Open Circuit Battery that they recently put on the market.

The Electrical Installation Company.

The Electrical Installation Company, Chicago, of which Mr. L. E. Myers is president, announce the removal of their offices to Suite A, 1116 Monadnock Building, where they have largely increased facilities.

Phœnix Rubber Insulating Paint.

Messrs. Morris & MacCurdy of Indianapolis report an encouraging demand from all parts of the country for their new Phœnix Insulating Paint, and that those who have used it so far are emphatic in their praises. The company have erected a large warehouse and are now prepared to fill orders in any quantity at once.

Agencies are being established in every trade center.

The Mather Electric Company's Sales.

The Mather Electric Company of Manchester, Conn., report the sale through Messrs. H. B. Coho & Company, their New York contractors, of one 30 K. W. and two 50 K. W. direct-connected generators of their new type for Grace Chapel, Fourteenth street, New York City. Armington & Sims engines will be used.

The Walker Company is Coming to the Front.

The Walker Manufacturing Company, Cleveland, Ohio, closed the following contracts between March 1 and March 22, 1895:

Burhorn & Granger, 136 Liberty street, New York City, two 25 K. W. direct-coupled lighting generators.

Union Depot Railroad Company, St. Louis, Mo., forty-one double car equipments, eighty-two 30 H. P. steel motors.

Pittsburg Traction Company, Pittsburg, Pa., one double car equipment, two 30 H. P. steel motors.

Pittsburg, Crafton and Mansfield Passenger Railway Company, Pittsburg, Pa., one double car equipment, two 50 H. P. steel motors.

Federal Street and Pleasant Valley Passenger Railway Company, Pittsburg, Pa., two double car equipments, four 30 H. P. steel motors.

Suburban Rapid Transit Street Railway Company, Pittsburg, Pa., one double car equipment, two 25 H. P. steel motors.

Schuylkill Electric Railway Company, Pottsville, Pa., four double car equipments, eight 25 H. P. steel motors.

Chicago City Railway Company, Chicago, Ill., forty-nine double car equipments, ninety-eight 25 H. P. steel motors.

F. E. Snow, receiver Adrian City Electric Belt Railway Company, Adrian, Mich., one 60 kilowatt belted generator, three single car equipments, 25 H. P. steel motors.

Premier Motors and Batteries.

The following extracts from a personal letter recently received from Mr. M. R. Rodrigues, 19 Whipple street, Brooklyn, show an encouraging condition of the business in his line and are interesting:

"Trade has picked up wonderfully in the past month, and I have several orders for large quantities of our No. 2 Battery. Several outfits of motors and batteries have been shipped South (South America) through my export agents with whom I have written contracts. One special outfit went out to-day to Iquique, Peru, and also our No. 2 Cells to operate a kinetoscope. The Pacific Coast and Southern business hold about the same, and just now we have many inquiries regarding Fan Motors from there.

"Our leaflet, 'Where the Profit Comes In,' is ready for the trade only. This sheet gives our prices and also our cast-iron terms.

"This week we have put in a machine to turn out work that heretofore had to be contracted for, and before long I hope to make many improvements in the construction of the Premier Motors and the Premier Batteries.

' . . . I am pleased to see in your paper occasional notices of the Brooklyn Electrical Society. At present I have not much time to devote to it, but it is a good thing and deserves some credit. We have many earnest workers in it, and there may be something of interest coming from it when the laboratory is in working order. Two of the members have wired the place and the Edison Company of Brooklyn will turn on the 'juice' at an early day."

RECENT COMPANY ELECTIONS.

Consolidated Traction Company, Jersey City, N. J. Directors: Edward F. C. Young, John D. Crimmins, Peter A. B. Widener, Alexander J. Cassatt, Clement A. Griscom, Frank Thomson, Michael R. Shanley, Jeremiah O'Rourke, Thomas F. Ryan, George F. Perkins, Abram Q. Garretson, William L. Elkins, Elisha B. Gaddis, Thomas Dolan and Joseph B. Sandford.

Stoughton, Canton and Sharon Electric Railway Company, Stoughton, Mass. President, Hon. Elisha C. Monk: treasurer, Henry W Britton. Directors: Alfred Upham, Henry L. Johnson, Charles Tenny, Melvin Upham, George Mantle, A. M. Bridgeman, F. C. Monk.

INCORPORATIONS.

The Binghamton General Electric Company has filed a certificate of reduction of its capital stock from $400,000 to $280,000. The certificate is signed by Edmund O'Connor, Geo. W. Dunn, Geo. F. O'Neil, Geo. C. Bayless, Geo. W. Davenport and J. H. Roberts.

Ayer Electric Typewriter Company, Concord, N. H.—to manufacture electric and other typewriters; sell, buy, lease patents and machinery. Capital stock, $300,000. Promoters: Chester M. Sprague, Claremont, N. H.; Chas. A. Herbert, Concord; Henry E. Adams, Boston, Mass.

The Capitol Electric Engineering Company, Lansing, Mich.—to manufacture and sell electrical supplies, etc. Capital stock, $5,000. Promoters: A. Robinson, Geo. L. Robinson, E. P. Kinney, all of Detroit, Mich.

Chicago Western Coal and Mining Company, Chicago, Ill.—to manage, operate and conduct the business of mining and selling coal and other minerals; construct, maintain and operate plants, power houses and all the necessary appliances for producing electricity for light, heat and power. Capital stock, $500,000 Promoters: Edw. W Russell, Frank H. Russell, Lawrence Browne.

The Harrisburg and Cumberland Railway Company, Harrisburg, Pa.—to build and operate an electric railway from New Cumberland to Riverton, Whitehill and Shumanstown, Pa., with a branch to Newmarket. Capital stock, $36,000. Directors: Joseph J. Baughman, New Cumberland, president; S. M. Hertzler, Eberly's Mills; Joseph Kaufmann, New Cumberland; W. L. Gorgas, S. J. McCarrell, Frank R. Leib, Levi Brandt, F. P. Snodgrass, S. W. Flemming, Harrisburg.

The Multiphase Motor Company, New York City—to manufacture electric motors, machinery and appliances. Capital stock, $200,000. Directors: Alfred S. Brown and Watson D. Schram, of New York City, and G. W. Gardenier, of Nyack, N. Y.

The Automatic Telephone Company of Wisconsin, Chicago. Capital stock, $500,000. Incorporators: J. Harry Theobald, William T. Whipple and Maurice Rosenfeld.

The Snyder Electrical Company, Cleveland, Ohio—to manufacture and deal in chemicals, electrical and plating machinery and supplies; specialties of every kind; machinery and tools. Capital stock, $5,000. Promoters: Edward Snyder, Chas. E. Watson, M. M. Zellers, Geo. A Bunke, A. V Cannon.

The Enbalm Conduit Trolley Company (incorporated in W. Va.), New York, N. Y.—to acquire, manufacture, own and sell all sorts of machinery and inventions and construct and equip steam and electric railways, etc. Capital stock, $5,000,000. Promoters: Glenn S. Smith, Brooklyn, N. Y.; Oscar A. Enbalm, Clarence E. Sherin, New York City.

The Dover Electric Light and Power Company, Dover Plains, N. Y.—to carry on the business of lighting cities, towns and villages by electricity, and sell electricity for heat and power. Capital stock, $10 000. Promoters: Adolph Reimer, Catharine Reimer, Dover Plains; J. C. Muick, Brooklyn, N. Y.

The Providence Electric Thermostat Company, Kittery Maine—to manufacture and deal in heat and damper regulators. Capital stock, $100,000. Promoters: Lorin M. Cook, Frank M. Burrough, Providence, R. I.; Burton S. Cowles, Meriden, Conn.

The Kelsey Electric Railway Specialty Company, New Haven, Conn.—to manufacture electrical supplies and specialties and car supplies, hardware and machinery. Capital stock, $20,000. Promoters: Frank N. Kelsey, Chas. L. Wright, Wm. W. Miner, New Haven.

The Morage Valley Railroad Company, San Francisco, Cal.—to build and operate railroads in Contra Costa County by steam, electricity or other motive power; lease purchase and sell railroads. Capital stock, $500,000. Promoters: Angus A. Grant, Albuquerque, N. M.: Archibald J. McDonald, San Francisco: John T. Williams, Oakland, Cal.

The Lock Haven Traction Company, Lock Haven, Pa.—to operate passenger railways by cable, electrical or other means. Capital stock, $10,000. Promoters: Chas. A. Bragg, H. M. Mitchell, Geo. Breed, Philadelphia.

MOONLIGHT SCHEDULE FOR THE UNITED STATES.

ELECTRICAL PATENT RECORD.

LETTERS PATENT ISSUED MARCH 26, 1895.

ELECTRIC RAILROADS AND APPLIANCES.

536.250. Adjustable Switch for Trolley Systems. Montraville M. Wood, Chicago, Ill. Filed July 14, 1894.

536,256. Electric Railway-Switch. Rollin A. Baldwin, South Norwalk, Conn., assignor to the Fitch-Excelsior Switch Company, of New Jersey. Filed Oct. 24, 1893.

536,275. Supply System for Electric Railways. Charles E. Emery, Brooklyn, N. Y. Filed March 15, 1894.

536,374. Conduit Electric Railway. Frederick S. Davenport, Jerseyville, Ill. Filed Jan. 28, 1895.

DYNAMO ELECTRIC MACHINERY.

536,226. Magnetic Separator. James D. McKinnon, Portland, Oreg. Filed Aug. 7, 1894.

536,438. Electric Mining-Machine. Edmund C. Morgan, Chicago, Ill. Filed July 18, 1894.

536,439. Armature for Electric Machines. Edmund C. Morgan, Chicago, Ill. Filed July 18, 1894.

TELEPHONE AND TELEGRAPH APPARATUS.

536,233. Telephone System. John I. Sabin and William Hampton, San Francisco, Cal. Filed Nov. 9, 1894.

536,382. Telephone Exchange System. Silas W. Holman, Boston, Mass. Filed March 24, 1894.

536,420. Telegraphy. Patrick B. Delany, South Orange, N. J. Filed Nov. 19, 1894.

536,481. Telephone. Jonathan D. Price, Chicago, Ill. Filed July 30, 1894.

536,559. Relay. Cyprien R. J. Willot, Paris, France. Filed Nov. 24, 1893.

SIGNALS AND SIGNALING APPARATUS.

536.210. Electrical Signaling Apparatus. William E. M. Jackson, San Francisco, Cal. Filed June 8, 1893.

536,271. Electrical-Signal and Switch-Operating Apparatus. Justin Dutrey, New Orleans, La. Filed July 19, 1894.

536,467. Electric Signal System. Webster Gillette, New York, and Alexander S. Williams, Long Island City, N. Y.: said Gillette, assignor to said Williams. Filed Oct. 30, 1894.

536,547. System of Electrical Signaling for Railways. Charles Seiden, Baltimore, Md. Filed Dec. 26, 1894.

MISCELLANEOUS.

536,184. Method of Applying Insulation. Frank E. Case, Schenectady, N. Y., assignor to the General Electric Company of New York. Filed June 21, 1894.

536,221. Electric Switch. Charles J. Miller, Philadelphia, Pa. Filed Jan. 19, 1895.

536,266. Electric Switch. Cummings C. Chesney, Pittsfield, Mass., assignor to the Stanley Laboratory Company, same place. Filed Jan. 17, 1895.

536,311. Fusible Cut-Out. James J. Wood, Fort Wayne, Ind. Filed Dec. 27, 1894.

536,319. Method of Insulating High-Tension Coils of Transformers. August Schneller, Aalanderveen-Alfen, and Willem J. Wisse, Haarlem, assignors to Henry Tindal, Amsterdam, Netherlands. Filed Dec. 27, 1894.

536,411. Velocipede Provided with Electrical Communicating Apparatus. Raphael H. Wolff, New York, N. Y. Filed Aug. 18, 1894.

536,478. Combination Electrical Meter. Herschel C. Parker, Brooklyn, N. Y. Filed Jan. 9, 1895.

536.530. Electric-Current Regulator. Charles M. Jordan, Washington, D. C. Filed Feb. 13, 1895.

536,535. Electric Brake. Edward D. Lewis, Savona, N. Y. Filed Nov. 12, 1894.

RE-ISSUE.

11,481. Closed-Conduit Electric Railway. William Lawrence, New York, N. Y., assignor to the Lawrence Electric Company, same place. Filed March 26, 1894. Original No. 516,631, dated March 14, 1894.

ELECTRICITY.

VOL. VIII. NEW YORK, APRIL 10, 1895. No. 13

ELECTRICITY

Published every Wednesday by the

ELECTRICITY NEWSPAPER CO.

B. E. GREENE, PRES'T. L. J. MONTGOMERY, SEC'Y.

PUBLICATION OFFICE:

6 Park Place - New York

EDITORS: NELSON W. PERRY.
BURTON E. GREENE.
R. H. WILLOUGHBY.

BUSINESS MANAGER, - - JOHN L. GANS.

SUBSCRIPTION RATES:

UNITED STATES, - - - - $2.50
IN CLUBS OF FIVE OR MORE, - - - - - $2.00
FOREIGN COUNTRIES, - - - - - - $4.50
SINGLE COPIES, - - - - - - 10 CENTS

ADVERTISING RATES:

As ELECTRICITY reaches all classes interested in electrical work, its value as an advertising medium can be readily appreciated. Rates will be sent on application.

Changes for advertisements should reach the office not later than the Saturday preceding the date of publication.

ENTERED AT THE N. Y. POST OFFICE AS MAIL MATTER OF THE SECOND-CLASS.

TRADE SUPPLIED BY
THE AMERICAN NEWS COMPANY,
THE WESTERN NEWS COMPANY,
And their Agencies in all Principal Cities.

EDITORIAL NOTES.

ELECTRICITY *states upon authority that up to the hour of going to press no agreement of any nature has been made between the Westinghouse and G. E. companies. That any agreement can be made is growing more and more improbable.*

* * *

Storage Battery Possibilities. The mail box of the newspaper which has achieved prominence along with a reputation for sturdy truth-telling and good judgment contains many interesting inquiries. Most of them are perhaps best answered by private correspondence. Occasionally a constituent asks something the answer to which is of public interest. We believe this to be the case with the following:

To the Editor of ELECTRICITY.

Dear Sir: Having recently been solicited to purchase some stock in a storage battery concern, and knowing that you are unusually well posted on the commercial possibilities of such undertakings, I would esteem it a favor if you will advise me what your opinion is. Is there sufficient demand for the product to make success possible?

Yours truly,

New York, April 8. INVESTOR.

Answering the last question first, yes. We suppose there might be a gross business of $250,000 a year for a well-managed concern in this line to be built up within two or three years. It might reach $1,000,000 in five years. At present the first figure is much above the value of the total output in this country. A company, therefore, going into business on the square, without a ballooned capitalization, ought to make a reasonable success.

So far the experience of the capitalist in storage battery ventures has been disastrous because he has been led to expect impossibilities. The storage battery promoter in years back has been a species all to himself. He has claimed that with *his improved* system the laws of nature were turned over, and that any kind of work possible for a steam engine direct could be better done by the storage battery as an intermediary agent. Hence the road has been strewn with wrecks, large amounts of money lost, hopes blasted, and investors disgusted. Whereas if the promoter had told the truth for the past ten years, as would have been to his best interests, the application of storage batteries, in *proper* places, would have been ten times what it is to-day.

It has now come to a point where the entire notion is in dispute almost everywhere, and all this hostile feeling has got to be overcome. It can be beaten down only by the frankest truth-telling. Continued deception will but further retard legitimate development.

Of course, however, continued deception, if practised in an artistic manner, may sell stock.

* * *

The Religious Press and Electro-Medical Frauds. It has become an axiom among promoters of questionable projects that the religious press of all class publications is the most easily satisfied to accept for pay the advertisement of their wares. Humbugs and frauds which even the daily press rejects as unfit for its columns are often greedily sought after by the editors of religious papers of easy conscience simply because of the financial returns which they bring. Many of the papers of this class seem to draw the line only at such advertisements as greengoods, lotteries and assignations, and then only because these have already been officially declared illegal and their insertion would subject them to the penalty of the law and a forfeiture of mail privileges. These papers by their conduct hold religion up to ridicule and should be disavowed by the Church which they pose as representing. Fortunately not *all* of the religious papers are of this class, and there are a few whose names we have mentioned from time to time that conscientiously endeavor to keep their advertising pages as pure as the gospel they preach. Such papers are an honor to the press and the cause which they espouse and have done much to remove the ill-repute into which their confreres as a class have fallen.

The occasion for these remarks is the announcement in the New York *Evening Post* of last week that "The Rev. Dr. William H. DePuy, assistant editor of the *Christian Advocate*, will retire the first of May, to devote himself to a literary work in which he is interested."

It will be remembered that Dr. De Puy has figured as one of the most blatant indorsers of the Electropoise, and that wherever his name has been used in that connection it has also been used in connection with his assistant editorship of the *Christian Advocate*—thus virtually implicating that paper in his endorsement. Our attention was called to the fact that Dr. De Puy's endorsement was that of the individual and not of the paper with which he was officially connected, and it was argued that so long as the individual performed his editorial duties satisfactorily to the editor-in-chief it mattered not what his private beliefs were.

We replied that while that might be strictly true in some cases, it certainly should be a matter of concern to the editor-in-chief when those private beliefs were of such a nature and published in such a way as to involve the good name of his employers. We are glad, therefore, that our view has been accepted as the correct one, and congratulate the paper for having decided to relieve itself of an incubus that not even so strong and correct a journal as the *Christian Advocate* can carry without contamination. The religious paper, like Cæsar's wife, should be beyond suspicion, and now that Dr. De Puy has withdrawn to literary pursuits he may pursue his puffing of the Electropoise unhampered, and at the same time without dragging down into dishonor with himself a publication which is and ought to be the repository only of the good and true. The Electropoise killed Dr. De Puy.

* * *

Patents and Combinations. If the electrical combination which has been talked of as an offensive and defensive alliance on patents needs any further discussion, a study of the full text of Judge Baker's recent decision at Indianapolis furnishes food for thought.

The National Harrow Company had brought suit for infringements of their patents against an independent manufacturer and asked for an injunction, which was refused. An abstract of the decision appears on another page. It will be noticed that infringement was not denied by the defendants. They rested their whole case upon the contention that the plaintiffs were a combination to control prices and hence had no standing entitling them to the assistance of the Court in enforcing their claims. This was the view taken by the Court, and the words of the decision are clear and emphatic.

Judge Baker is a man of high standing in his profession, whose decisions are looked upon with great respect by the judges in other circuits. It is fair to suppose that his opinion will be sustained by the higher courts.

While the intention of the framers of our patent laws was unquestionably to confer a monopolistic privilege upon the inventor, it is equally certain that they did not comprehend the possibilities for evil of the trade combinations which have come into being in the last twenty years. The monopoly of an individual patent-holder in his property is necessary and operates for the public good. The monopoly intended in trade combinations like the National Harrow Company, and the General Electric Company is not for the public good but for the public injury. Such combinations are rarely if ever of benefit to the inventor himself. They are hindrances in the way of development, barring all progress to whatever extent they can. They are created for the purposes of oppression and operate to prevent the man of small capital from enjoying his natural rights. They create a dangerous weapon in the hands of unscrupulous promoters and schemers which it is impossible to suppose was intended by the founders of our Government to bestow when giving protection to the actual inventor or to his legitimate backers.

It is to be hoped that our constituents will read Judge Baker's decision carefully, that they will study closely the status of electrical patents, and ask themselves what would be the chances for winning on any possible plan for patent litigation by a combination of any character against the smaller concerns.

They should moreover read Electricity thoroughly each week. They will here find many incontrovertible truths laid before them and before the public in clear and intelligible language.

In the harrow case, *infringement* was not denied; the validity of the patent was not questioned.

What electrical patent would come into court with half as good a showing? The *validity* of any electrical patent of importance is open to serious question, and an unjust campaign of litigation against the smaller concerns would be stubbornly fought at every point.

Notwithstanding Judge Lacombe's remarks in the Sawyer-Man case, when the Westinghouse contention that the G. E. Company was a trust and attempting an abuse of its patent privileges was laid before him, it might now be found that even he has got additional light by this time upon the fundamental principles of common law.

* * *

The Tesla Motor in the Machine Shop. In this issue we give the first paper by Mr. Perry on the new Westinghouse Electric and Manufacturing Company's shops, fitted throughout with Tesla two-phased motors, which cannot fail to interest our readers. Since it has been announced in the papers that a preliminary test of one of the great Niagara generators was made last week, the subject of the utilization of the two-phased currents which are to be generated assumes new interest, and Mr. Perry's article is therefore most timely. Those who are contemplating the erection of factories at Niagara have questioned the ability of this system to adapt itself to all the varied requirements of their demands. The Westinghouse plant answers these questions in a most positive manner, for with the single exception of electrolytic work almost every conceivable class of work is already being done successfully without the rectification of the current, and with this rectification, which is also exemplified in these same works, even electrolytic work is rendered entirely feasible. At East Pittsburg the generators are of the same general type as those at Niagara, viz., they produce two-phase alternating currents of exactly the same frequency as do the latter. The Westinghouse shops might therefore be hitched directly on to the Niagara circuit and continue in operation as now without the change of a pulley, a motor or a tool. They will therefore serve as a most important object lesson, not only to those contemplating removal to Niagara, but to other users of power having two-phased currents at their disposal. Aside from all this, these new works undoubtedly constitute the most complete electrical shops in the world of any kind, and the only ones using the two-phase currents for all operations.

In the first paper Mr. Perry confines himself to a general description of the plant. In the second he will describe its operation.

Our review of what is being done at Pittsburg has exceptional interest at this time from the fact, and it is a fact, that in the discussions of a patent agreement between the Westinghouse and G. E. interests, the latter have admitted that the Westinghouse Company has an undoubted legal right to actual proprietorship in these methods of alternating current transmission. It is admitted that the monocyclic system exploited by the G. E. Company is directly an infringement of the Tesla patents owned by the Westinghouse Company.

In the disappointment of Mr. Tesla at the delay in placing some of his later work before the public in commercial form, there must be a measure of satisfaction in realizing that his earlier work is proving all that he claimed for it practically and that the world recognizes that he is entitled to the credit.

In obtaining control of this system, the Westinghouse Company exercised exquisite foresight, and they are entitled to the full measure of practical benefit.

Under the Searchlight.

Views and Opinions on Timely Topics.

In view of the report that Mr. F. P. Fish has retired from his salaried connection with the G. E. Company, is it too much to expect that he will come forward and tell what he knows as to the purchase of the charter of the G. E. Company in this State. What day was it that a G. E. employé, now in Europe (?), went over to New Jersey to pay out the money? How much did he pay? Was Mr. Fish an active or a passive agent in this matter? The money being paid in New Jersey, where was the crime committed? Is the charter of the company, which can be proved to have been obtained by criminal methods, still valid?

Mr. Fish has contemplated a libel suit against Electricity. Now that he is again a free man, why don't he bring it?

* * *

And why does not Mr. Coffin himself defend his reputation? Is he waiting for an exposé of Northwest G. E.?

* * *

Taking time by the forelock, many of the independent manufacturers have already come together for consideration, and a strong combination for the defence of patent suits brought by the G. E. or any other combination is a foregone conclusion.

* * *

The Fort Clark, Ill., Railway, in which the

G. E. Company holds $177,000 of stock, has been allowed ten days in which to pay a claim of $297,583.36. In default, a decree of sale will be issued.

* * *

GENERAL ELECTRIC.

Preparing the Public for Another False Statement.

(From the Boston News Bureau.)

A great deal has been heard about the patent account of the General Electric Company. As a matter of fact the so-called patent account is the item of "patents and franchises $8,159,264," which has been unchanged since the organization of the General Electric Company, and its value at the present time has not been so seriously impaired as the records of the patent department and law courts might lead one to believe, as the licenses and franchises from that account still pay the company about 5 per cent., or $400,000, on its total capitalization, and in some years about $500,000 has been received.

The last annual report of the General Electric Company showed a book value of $59 per share, including this patent and franchise account, whose valuation amounted to $26 per share. Therefore at $27 per share (lowest price March 4 at 25⅝) General Electric was sold for $6 per share less than its book valuation with the entire patent and franchise account eliminated. This book value a year ago of $59 per share was after the revaluation which wiped off the company's books $14,600,000.

The foregoing is so peculiarly Coffinesque in its tone that its authorship is unquestioned.

It may be accepted as official notification that the $8,000,000 patent account is not to be scaled down in the forthcoming report.

The statement that the item of $8,159,264 "has been unchanged since the organization of the G. E. Company" is not entirely correct.

The statement filed at the Stock Exchange May 31, 1892, when the G. E. Company was organized, showed this account to be as follows :

T.-H. patents	$338,354.29
T.-H. Int. Company patents	286,110.99
Edison Company patents	332,551.22
*Stock of Edison Electric Light Company	3,826,099.25
*Stock of Sprague Electric Company	680,000.00
Total	$5,463,115.75

*The only value claimed for this stock was in the patents owned by the companies.

Eight months later, when every effort was considered necessary to make a false showing in order to avert a collapse, this account had been marked up as follows for the first annual report:

Edison patents	$4,239,168.32
T.-H. patents	3,389,352.07
T.-H. Int. patents	530,743.63
Total	$8,159,264.02

Thus, although these patents were decreasing in value rapidly, they have been marked up since the organization of the company just $2,696,148.27.

Since the issue of the last report the company has been beaten on two of its most valuable patents—the feeder and main and Thomson regulator—and the lamp patent has expired by limitation.

Perhaps the *News Bureau* does not know what the "royalties" are. We would suggest that, in order to prove Mr. Coffin's case for him, our contemporary should call upon him for information showing how many Edison licensees are still handing over any proportion of their additional issues of stock, and how the total for the year 1894 compared with the year 1893 or 1892.

These increases of stock of Edison licensees are the only royalties worth considering in fixing the value of the patent account.

* * *

The Best System Will Win.

(From the New York Sun.)

In the rivalry between the electric and the steam railroads in Connecticut, the Legislature of the State ought to refrain from interference. If the electric lines are injuring the business of the steam lines it must be because they enjoy economic advantages not possessed by the other. The cheaper and more serviceable of the two powers will surely win in the end, whatever be the legislation enacted in regard to it.

A TALE WITH A MORAL.

A few years ago two sturdy young farmers drove into the town of Eau Claire, Wis., to go to the circus. As usual the town was full—also most of the people. By afternoon, John and Bill had acquired two distinct varieties of jags. The former was quarrelsome, the latter happy as a king. Several times Bill interfered to save his friend when he was about to get into a fight. Finally there was trouble in earnest, and John was in it. Bill rushed in, grabbed his partner by the collar, and yanked him out. Then John struck Bill, and all was different. Bill landed with his right and left simultaneously, and John fell to the floor with Bill sitting on his wishbone, saying, as he finished the job : "Strike me, will ye—biff-biff. I'm your friend, —— ——ye (biff-biff)—the best friend ye ever had (biff)."

As Jack Bunsby would say, the bearings of this observation lie in the application of it.

* * *

THE Federal courts at Little Rock, Ark., are still busy with street railway litigation, and Mr. H. G. Allis is on deck to make it uncomfortable for his enemies.

* * *

WHERE, oh, where, is Mossback Westover? Has he been playing woodchuck during this long and dreary winter ?

* * *

A DIRECTOR of the G. E. Company who never has taken kindly to the methods adopted to get his name into the list, nor to the "green goods" game which has been played on the public, has promised to ELECTRICITY a statement of his views just as soon as his official connection with the concern is ended. It is not a long time to wait, and we think we are safe in assuring our readers that we will present a clearer story of the enterprise, with critical estimates of the men interested, than has yet appeared. It will be authentic, discriminative and just.

* * *

WE all know that rats desert a sinking ship, and ELECTRICITY knows that several gentlemen holding good positions in the G. E. Company are making other business arrangements.

* * *

BEFORE the reform administration in Brooklyn complete their labors of purification they ought to call some of the G. E. hustlers in to tell what they know about railroad matters in that town. Of course some of them are in Europe—or elsewhere—but they can't stay away forever. We wonder if there is any connection between their being in Europe and the matters referred to ?

* * *

THE St. Johnland lighting plant would be another nice job to investigate. Curtis & Dean might, under proper pressure, tell what they know of this.

* * *

WE suppose that in the late negotiations between the Westinghouse and G. E. companies the astute and brainy secretary of the latter company has exercised a commanding influence.

* * *

IT is not too much to suppose that Mr. H. M. Byllesby, who knows a good deal about the wrecking of the Northwest G. E., and who might be inclined to tell his story some day, will soon hold a high position in the G. E. Company.

* * *

MR. CHARLES W. PRICE of the *Electrical Review* has been in the South for two weeks recuperating after a severe attack of the grip.

* * *

THE last number of the *Electrical Review* was the most interesting which our contemporary has issued in several months.

THE G. E. Company now propose to accomplish by slaughtering prices what they failed to accomplish by years of litigation—clear the lamp field of all competitors. They will lose their money and their fight the same as before.

* * *

Was the Canadian Delegate There?

The following clipping from the *Canadian Electrical News* for March will be read with some amusement by those who really attended the Cleveland Convention :

> There was a larger Canadian representation than usual at the National Electric Light Association Convention held in Cleveland on the 19th, 20th and 21st of February. Among those who attended from Canada were Messrs. John Langton, Frederic Nicholls and J. K. Kammerer, of Toronto ; J. W. Taylor, Peterboro'; Frank Badger, Montmorency, Que., and J. A. Corriveau, of Montreal. The total attendance at the Convention numbered about 800. "It was the first of the American Conventions that I had attended," said one of the Canadian delegates, "and I was so disappointed that I am not in the least anxious to attend another. I had polished up my mental apparatus to the greatest possible degree, in anticipation of coming in contact with the brightest intellects of the continent. Judge of my surprise to find the discussions of the tamest character, and largely monopolized by sales agents of the various manufacturing companies for advertising purposes. One whole day was taken up with the discussion of the monocyclic system. I was surprised that the President of the Association made no effort to limit the discussion so as to allow time for the consideration of other subjects of general interest to the electrical fraternity. Mr. Nicholls' paper on 'The Lighting of Large Cities,' for example, received no discussion whatever. I consider that our Canadian Electrical Association can give the National Association pointers as to how to manage a successful Convention. The Canadian Association is noticeably superior in point of the ability of its members to present intelligibly their views upon the subjects up for discussion, and in their knowledge and observance of parliamentary practice."

We are sorry that the Canadian delegate was disappointed in the caliber of the intellects with which he came in contact, and also in the character of the discussions, which were not wild enough to meet his views. What did he expect—war paint, tomahawks, revolvers and bowie knives? But as to facts: he is so far astray as to lead to the supposition that he mistook the basement of the Hollenden for the Convention hall. As matters of fact, the discussions were *not* monopolized by sales-agents; one whole day was *not* taken up in the discussion of the monocyclic system, unless from 3 to 5:30 P. M. is called a whole day by Canadians, and Mr. Nicholls did *not* have a paper on "Lighting of Large Cities"—that was merely a topic for discussion. Unfortunately, the discussion did not amount to much, but just wait until the Canadian Association meets. We can then get pointers as to how to conduct such things, and perhaps do better ourselves in the future.

FIRE AT THE CROCKER-WHEELER FACTORY.

The Crocker-Wheeler Electric Company works, near Ampere station, at East Orange, N. J., were partly destroyed by fire on Sunday last. Over $100,000 worth of motors and dynamos, which were stored in the main building, were ruined, together with about $50,000 worth of machinery. The total loss will amount to about $250,000. The company is insured.

It was feared that the flames would spread to the office building, and all the books, drawings, etc., were removed.

Two hundred men are thrown out of employment by the fire. The company will rebuild at once, and the stoppage in the business will be of brief duration.

Correction.

We were incorrect in reporting last week that Judge Beekman had set aside the attachment obtained by the New York Insulated Wire Company against the Westinghouse Company's property in this State in the action brought for balance claimed to be due on the World's Fair contract. Messrs. Brayton Ives and Marcellus Hartley gave bond for $40,000 to secure the claim, pending final settlement.

RECEPTION AT THE BROOKLYN EDISON STATION.

That a central lighting station may be made a beneficent agency in other ways than that for which it was avowedly constructed has nowhere found a happier illustration than in the Brooklyn Edison station under the able management of Superintendent W. S. Barstow, President Ethan Allen Doty, and Secretary Royal C. Peabody.

From the very start these gentlemen have realized the potentiality for good which their station has placed in their hands, and they have been foremost in enlightening the minds of the community as they have been in illuminating its buildings. In them the cause of education has found a ready friend.

When the enlargement of their establishment was decided on, the plans included a very unusual feature, viz., a large lecture room where experimental demonstrations of electrical phenomena could be given from time to time as occasion offered. While this feature was primarily intended for the benefit of their employees, experience has shown that it has by no means been limited in its accommodations to them.

When the electrical section of the Brooklyn Institute was temporarily without a home, this lecture room with all the varied facilities of the great station was placed at its disposal. When, later, the Brooklyn Electrical Society was organized, composed of earnest young men, who met around from house to house for the purpose of improving their electrical education, these gentlemen saw the germ of a good thing and encouraged it in every way in their power. They took them in and gave them a home in this same lecture room until the society became strong enough to make a home for itself, and when the new quarters were procured gave many evidences of their continued interest in the shape of equipment of their new laboratory.

Last week the Edison Company inaugurated a new step in the educational scheme by which its benefits were extended more directly to the general public than had previously been possible. The new step consisted in affording to the public an opportunity of seeing not only one of the very finest electrical stations in the land, but also the manifold and varied applications of the electric current to the uses and comfort of man.

To the average layman the interior of an electric light station is a *terra incognita;* it is the abode of mystery through whose portals he may not pass. There is usually no *open sesame* to these portals, but last week this was afforded by handsomely engraved invitation cards sent for Wednesday evening by the officers of the company to their friends and patrons, and for Thursday evening by the employees to their circle of immediate friends and admirers. On the first occasion the officers as hosts were ably assisted by their employees, and on the second the employees as hosts were as ably assisted by the officers.

The mere opportunity to visit the station would have been sufficient to call out a large attendance, but on this occasion it had been announced that among the specialties on exhibition there would be the following: Electric piano, electric ice-making, electric cooking, electric motors, electric pumps, electric dumb-waiter, electric medical apparatus, electric forge, illustrations of the street lighting system; and from before 8 P. M. until 11 the throng of ladies and gentlemen continued almost undiminished in numbers.

The Otis electric elevator carried the expectant visitors to the third floor, where the operating offices of the company, brilliantly lighted, were open for inspection. In some of these the various testing and measuring instruments used by the electrician were exhibited and their mysteries explained by untiring young gentlemen. In another room the endeavor was made to make clear to the customer the beauty and infallibility of the electric meter by which his bills are rendered monthly, and the delicacy of the chemical balance by which the deposited zinc was weighed was illustrated by a charming young lady to the crowds that gathered around her.

In the passageway leading to the lecture room had been erected a narrow platform upon which were shown electrical curling-irons for the ladies, radiators and cooking utensils, goose-irons, glue-pots, etc., etc., illustrating the adaptation of electricity to the domestic arts of heating and cooking, electric motors of the Lundell, Crocker-Wheeler and C & C types, illustrative of the application of the current to power; and in this connection was shown a Quimby electric elevator pump, which consisted of a combined electric motor and rotary pump, forcing water into a small glass tank near the ceiling. The complete apparatus, including automatic switching apparatus and all, just as it is installed in connection with the ordinary hydraulic elevator, was shown in miniature in operation.

Above these exhibits, along the wall, were shown a profusion of the latest designs of incandescent lamps and shades, in colors, frosted and clear, illustrating the artistic adaptation of the electric light.

Passing into the lecture room, the first exhibit to meet the eye was the mechanism of a full-size electric elevator of the well-known A. B. See Manufacturing Company's type. This, having all its working parts exposed to view, proved perhaps more interesting to the electrical engineer than to the layman, but the extreme ease with which its every motion was controlled by the attendant could not fail to attract the attention of even the layman, and its great simplicity and economy were manifest to all.

Next in order were two extensive exhibits of electro-therapeutical appliances showing the benign applications of the electrical current to the healing art. These exhibits were made by the Monarch Company and Messrs. J. C. Vetter & Company.

Electric cooking was practically illustrated along the south wall of the room, where Mrs. Lempke showed the roasting of meats and the baking of cakes to a most appreciative audience.

In another corner of the room was the electric piano, whose keys, touched by unseen hands, gave forth classical as well as popular strains to the admiration of all present. We noticed among the most attentive listeners around this piano an unusually large proportion of young ladies—doubtless from the Packer Institute. Probably these were thinking how beneficent the mission of electricity would be if only electrical pianos could be made to do their "practising" for them at the Institute.

Passing down a narrow iron stairway, the visitors were ushered upon the regulating gallery of the power room. Here a birdseye view was had of the great engines and dynamos and other mechanisms that are essential to the production of the electrical current, and to many this was the most marvelous sight of the evening. In the gallery itself was the long, silent distributing switchboard, by which the currents in all parts of the city are controlled, with its accessories, the rheostats and indicating instruments. Below—so far down that it almost made one dizzy to look at them—were the two great engines of 1,500 H. P. each, with their dynamos, nearly as silent as the switchboard itself yet sending out thrills over miles and miles of wire into every precinct of Brooklyn as well as providing current for the wonderful applications just witnessed.

And yet one more thing was best seen from this gallery—the great 15-ton electric traveling crane, erected by the Morgan Engineering Company of Alliance, Ohio.

This spanning the great power hall, nearly 65 feet in length, traveled the whole length of 100 feet, and on its own surface bore a carriage or buggy which traversed it longitudinally. Suspended from the center of this great span, in a little cab hanging in mid air, 30 or 40 feet from the floor, stood the motor man, who by pulling this lever or that directed this mighty mechanism so that the hoisting apparatus could be brought over any piece of machinery on the floor. It was by means of this great crane that the enormous engines and dynamos were lifted as a mother does a child and placed in their present position. It is by means of this crane that they will be taken apart should they at any time require repair, and it will be by means of this same mechanism that other great engines and dynamos will be installed when the rapidly increasing demands for current render them necessary.

Descending from the gallery to the ground floor, the visitors passed by the great dynamos and engines, and thence to the open space not yet required by the demands on the station. Here was viewed a small refrigerating apparatus erected by the De La Vergne Refrigerating Machine Company—this, too, operated by an electric motor; hence indirectly they saw the process of manufacturing ice by electricity. As if to add contrast to the uses of electricity, side by side with the ice machine was exhibited the waterpail forge, fully described some months ago in ELECTRICITY. Here the anomalous condition was observed of raising iron bars to a welding heat by simply immersing them in a pail of water.

Nearby were shown and explained the Edison conduit system, by which all of the electrical currents from this station are distributed over Brooklyn, and also the time mechanism employed in the new ornamental arc lampposts, by which, on somewhat the same principle as the alarm clock, the lamps may be turned on or off at any predetermined hour.

From this last inspection the visitors passed out into the street if they so desired, but many returned by the electric elevator to the third floor and inspected again the interesting features which they had first seen.

This occasion was one for mutual congratulations—for congratulation among the residents of Brooklyn that they had had the opportunity of witnessing such a comprehensive display of the possibilities of electricity, among the Brooklyn Edison Company that their efforts were so highly appreciated by such an intelligent constituency.

A Hollander has invented a process of sterilizing milk by subjecting it to the passage of an alternating electric current. All micro-organisms taken up by the milk from the air, etc., are permanently destroyed by the electric current. This germ-killing quality of the electric current does not hurt the milk, but a longer experience only will teach us whether this system can be applied to large quantities with the proper result.

The Faraday medal of the Chemical Society of London has been conferred upon Lord Rayleigh in recognition of the investigation which has led to the discovery of argon. The previous recipients of the medal are Dumas, Canizzarro, Wurtz, Helmholtz and Mendelejeff.

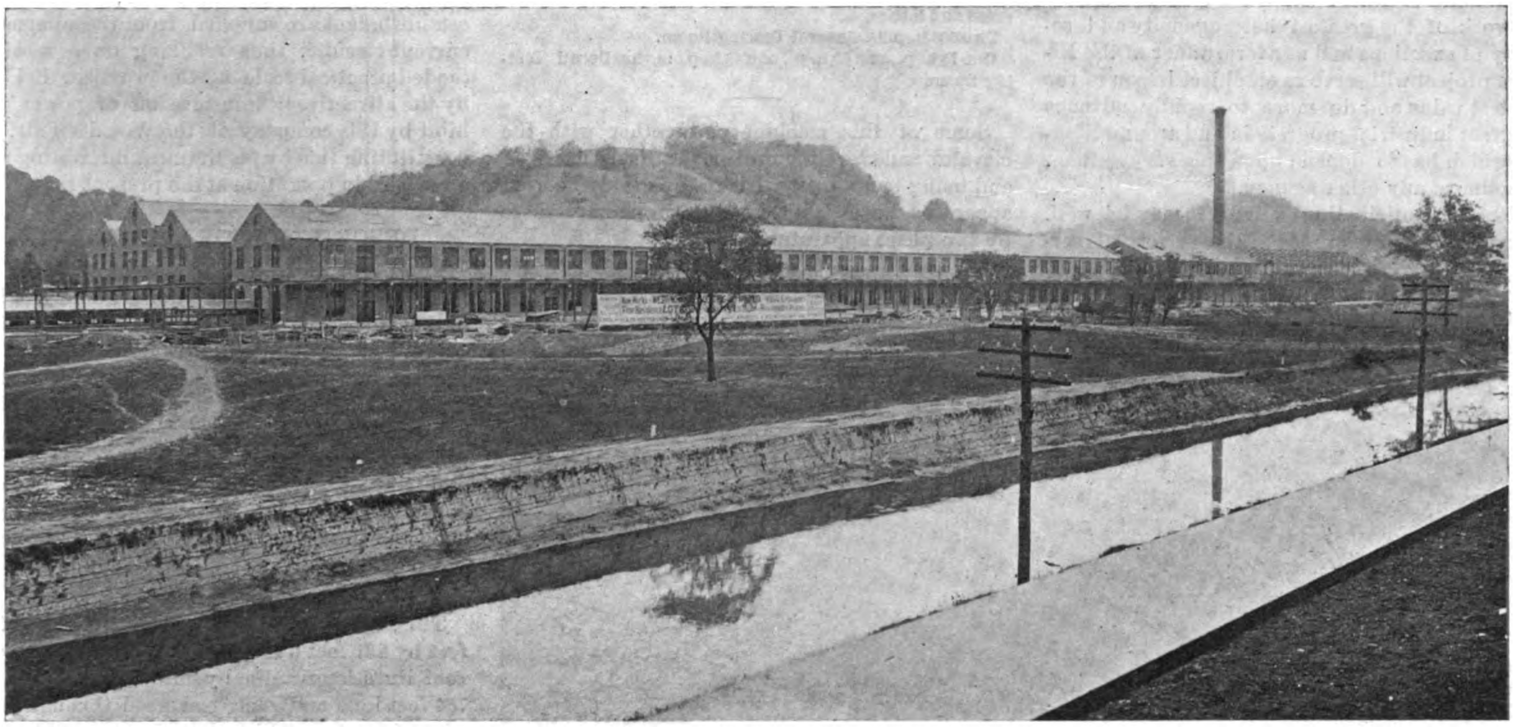

FIG. 1.—WESTINGHOUSE ELECTRIC AND MANUFACTURING COMPANY'S PLANT, BRINTON, PA.

The Tesla Two-Phase System.

Extensive Use at the Westinghouse Works, Brinton.

The New Plant Fully Equipped with Alternating-Current Apparatus—The Most Important Installation Thus Far Attempted.

BY NELSON W. PERRY, E. M.

For many years it was a matter of reproach to the electrical industry that the manufacturers of electrical apparatus who zealously urged its adoption in all other industries failed to use it in their own. While recommending their wares to others they used them not themselves, except in a few isolated cases where small electrical apparatus was erected in the works to show to prospective purchasers that it would run under favorable circumstances. On the conservative business man the claims of superior economy, efficiency and convenience made for electrical methods produced rather the opposite effect to that intended when he saw in these great establishments the same methods in vogue which their proprietors were urging him to discard in his own.

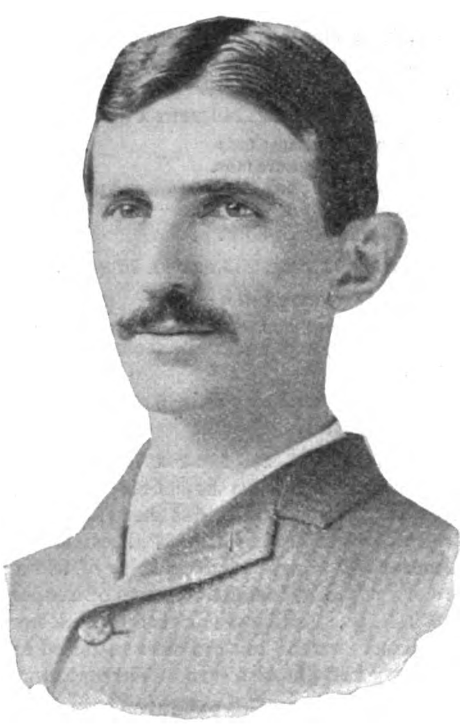
Gradually, however, things changed, and the electrical manufacturer began himself to follow the advice which he had so long been giving to others.

Direct current methods are the oldest, commercially speaking at least, and first reached a perfection leaving little to be desired; and for some years past several of our largest electrical companies have been distributing power throughout their works by electrical means instead of by long belts and shafting, and have driven almost all of their tools either directly from direct current motors or from short lines of shafting driven locally in the same way.

Next in point of time came the simple alternating current which seemed to present possibilities for the future which would relegate direct current practice to the rear. For incandescent lighting purposes and long distance transmission *per se* it seemed all-sufficient almost from the invention of Gaulard and Gibbs, but for motor service it proved inadequate to the demands. Early in the history of the art alternating current motors of good efficiency had been constructed, which, when once brought up to speed, would do good work, but from that day to this, notwithstanding the persistent efforts of the best talent, a simple alternating current motor that could be started and stopped and reversed while under load, and thus fulfil all the requirements of commercial practice, has not been built.

From time to time claims have been made that this has been accomplished, but the test has never verified the promise. Not until the invention of the polyphase motor by Nikola Tesla, in which two or more simple alternating currents differing in phase were employed, was the alternating current adapted to the demands of commercial power practice.

Although Tesla's seven earliest patents were issued on May 1, 1888, followed by four others during the same year, the value of the polyphase system was not generally realized until 1891, when the Frankfort-Lauffen experiment attracted world-wide attention to its merits. Both before and since that date, however, many modifications of Tesla's method had sprung into existence whose claims for utility were strongly urged by their respective promoters, and the history of the direct current method from the manufacturer's standpoint was repeated. Although extraordinary claims were advanced for these systems, and latterly numerous successful installations had been made, the manufacturer himself neglected them in the equipment of his own shop. With one or two exceptions, while the manufacturer of alternating current apparatus equipped his factory with electrical power apparatus, it was of the direct current type, which his own wares were professedly intended to supplant by reason of their superiority.



NIKOLA TESLA.

There were often more or less valid reasons for this seeming inconsistency, but the public knew them not, and from this circumstance, perhaps, more than any other has looked upon polyphase systems with lack of confidence, if not suspicion.

The greatest difficulty that the manufacturer has had to contend with in replacing an established system by a new one, has been to adapt the speeds of the new motors to the old pulley relations—either this had to be done or the pulley relations had to be adapted to the new motor speeds, either of which would involve an expense scarcely warranted by the results.

But when the Westinghouse Electric and Manufacturing Company began equipping their magnificent new works at East Pittsburg they were hampered by neither of these considerations, and were left entirely free to choose that system which they thought promised the best results. This company being the owners of all the Tesla polyphase patents, had for years been recommending the system to their patrons as universally applicable for general power distribution; and they have given evidence of their faith in the system by equipping their new works throughout with it.

This plant, which is now described for the first time, though not yet complete, forms the most interesting installation of polyphase apparatus thus far made, for several reasons. In the first place, the same type of apparatus, the same method of distribution and the same frequency of alternation of current (3,000 per minute) are employed as are to be used at Niagara. Its sufficiency for all the multifarious demands of these large works is therefore a demonstration of its sufficiency for all the demands that can be made upon it at Niagara. Furthermore, it is the first practical demonstration of this on a sufficiently extended scale to settle the matter beyond question. In the second place it is the first demonstration on a practical scale of the system to machinery and work of the greatest heterogeneity and severity of exactions and as a forerunner of the Niagara project will serve as an object lesson of the greatest value and do more to rapidly advance the great industrial progress in and around Niagara, which has to depend upon this very system, than almost any other agency.

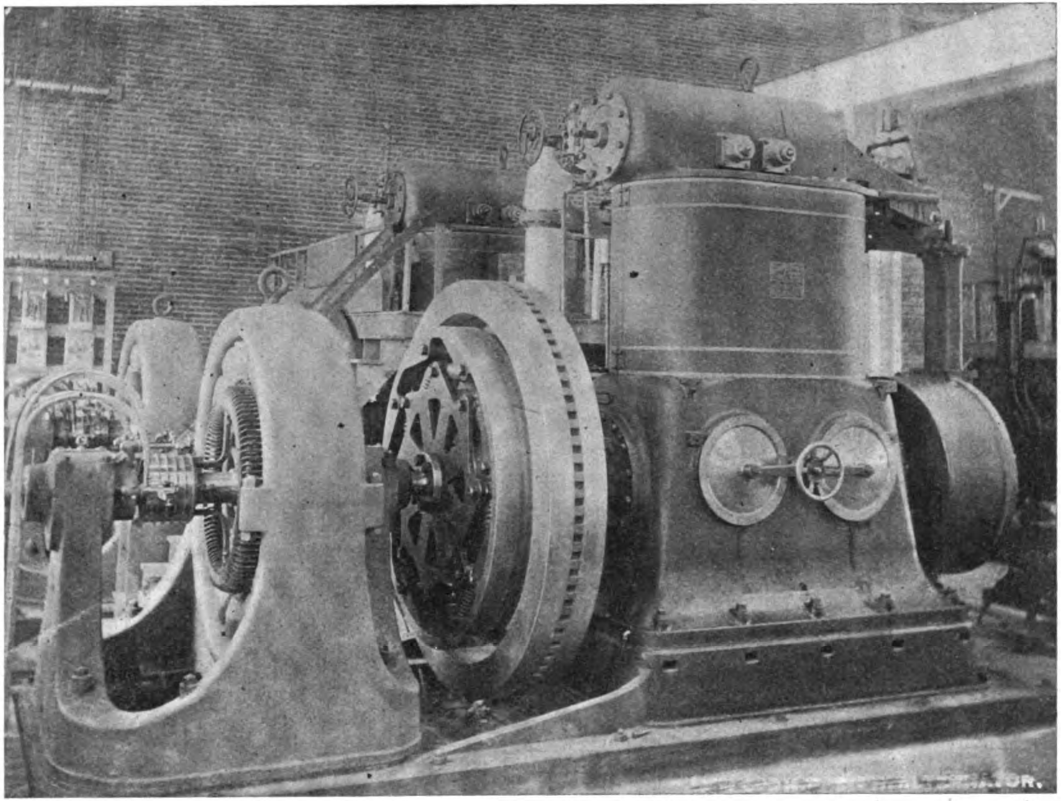


FIG. 2.—TWO-PHASE GENERATORS FURNISHING POWER AND LIGHT TO THE WESTINGHOUSE SHOPS. 500 H. P. UNITS.

Although anticipating a little, it may be well, in order to convey an idea of the variety of service that this system is supplying in the Westinghouse works, to catalogue the apparatus it is now driving.

PRESENT INSTALLATION.

Main Machinery Building, 754 feet long by 235 feet wide.

SMALL GENERATOR DEPARTMENT—MACHINES BELOW 100 H. P.

Ground Floor—

Two 40 h. p. motors each, driving planers, drill presses, lathes, etc., to the number of about 100 machines.

Galleries—

One 30 h. p., driving about 40 screw machines of various sizes.

Two 30 h. p. each driving 40 tools of various kinds in Too Department.

One 40 h. p. driving about 40 tools of various sizes in Commutator Department.

One 20 h. p. driving about 25 or 30 tools in Brush-holder Department.

One 30 h. p. driving about 60 tools in Controller Department.

One 20 h. p. driving about 15 tools in Converter Department.

One 20 h. p. driving 15 punches and various tools in Mica Department.

Four 20 h. p. driving 200 winding lathes.

Six 40 h. p. driving fans for heating.

Making 20 motors of an aggregate of 620 h. p. already installed in this building.

There still remain to be installed in this building the following motors:

One 30 h. p. to drive 3 Ingersoll milling machines.

Two 30 h. p. in Railway Motor Armature Department, each of which will drive some 40 tools, lathes, etc.

One 15 h. p. in Motor Armature Winding Department.

Two 30 h. p. in Motor Machinery Department, each driving some 30 heavy tools, boring mills, lathes, drills, etc.

One 30 h. p. to drive 3 boring mills, one 122 inch by 35 inch lathe, two 72 inch radial drills, two large planers.

One 30 h. p. to operate planers, boring mills and drill presses.

Three 20 h. p. to drive large planers, boring mills, drill press and lathes.

Two 500 h. p. in General Testing Room.

One 75 h. p., one 60 h. p., one 40 h. p. in the Detail Testing Room.

Some of this machinery, together with the elevator and traveling cranes, is already installed and being temporarily driven by direct current apparatus, but it is intended to supplant all these by two-phase apparatus.

WAREHOUSE, 76 FEET X 754 FEET.

Motors already installed—

Four 20 h. p., each driving some 40 tools.

Two 30 h. p., each driving some 45 tools.

Two 40 h. p., each driving fans for heating purposes.

Making 8 motors of 220 h. p.

CARPENTER AND CABINET SHOP, 192 FEET X 60 FEET.

100 h. p. in small units, all direct current at present, but to be replaced with two-phase motors.

BLACKSMITH SHOP, 242 FEET X 82.6 FEET.

Two 20 h. p., on exhaust fans.

Two 10 h. p., on pressure fans.

One 20 h. p., driving two large shears and punches and 5 smaller tools.

Total—5 motors of 80 h. p.

POWER HOUSE, 206 FEET X 76 FEET.

At present this contains—

Two 500 h. p. direct connected alternating current (two-phase) and two 500 h. p. direct connected direct current machines.

The full complement will be 3 units of 500 h. p. each of each kind.

PUNCH SHOP, 258 FEET X 76 FEET.

Two 30 h. p., each driving 40 odd punching machines.

Recapitulating, we find that there are at present installed and in operation 37 alternating current motors of an aggregate capacity of 980 h. p. There are yet to be installed 16 more of a capacity of 1,390 h. p., besides several hundred horsepower direct current motors now installed to be replaced by two-phase alternate current motors.

It will be seen from this catalogue that the new plant constitutes by far the largest installation of polyphase motors that has heretofore ever been attempted and that these motors are doing almost every conceivable class of service except electrolytic work. In addition to this, all of the lights, both arc and incandescent, for the whole establishment are supplied from the alternating current circuits, thus realizing on a most extended practical scale all the promises held out by the attractive "transmission of power" exhibit by this company at the World's Fair, and constituting this by far the most interesting plant anywhere in operation at the present time.

DESCRIPTION OF THE PLANT.

The site of the Westinghouse Electric & Manufacturing Company's new shops, which has been christened East Pittsburg, is 12 miles from Pittsburg, on the Pennsylvania Railroad. The buildings at present erected and occupied are seven in number, and in the order of size are the main machine shop, warehouse, punch shop, blacksmith shop, power house, carpenter shop, and temporary brass foundry. All of these are substantial brick buildings except the carpenter shop and the brass foundry, which are of corrugated iron.

THE MAIN MACHINE SHOP.

This, by far the largest, covers an area of 754 feet by 231 feet 6 inches, and is divided by the roof lines longitudinally into three aisles, each 754 feet long and each traversed throughout its whole length by railroad tracks connecting with the main line of the Pennsylvania Railroad. The main aisle is unbroken from floor to roof and traversed throughout its length by a 30-ton electric crane. Here all the heavy machine work and large generator erecting is carried on. The side aisles are both divided midway of their height by floors, under which in each case is a 10-ton electric crane with a 754-foot runway.

On the ground floor of the north aisle are located the motor armature winding, fitting, and assembling departments and storerooms, and in the south aisle are found the small generator department, small generator armature winding and assembling departments and more storerooms, and the entire eastern quarter of the three aisles as general testing rooms for the classes of work done in their respective western portions.

On the second floor of the north wing, beginning at the west and going east, are the screw department, tool and storeroom, brush-holder department and railway equipment rooms, and similarly situated in the south wing are the wire storeroom, winding and insulation department, mica department, detail testing room and converter department.

Each of these longitudinal sections of the building is traversed by line shafting divided into numerous sections, each of which is belted to an individual two-phase motor situated on the floor, and from which are belted the various tools and machines already enumerated. This plan of transmission from motor to tool is observed throughout the various buildings and need not be again referred to. It may also be stated here that with the exception of three small steam

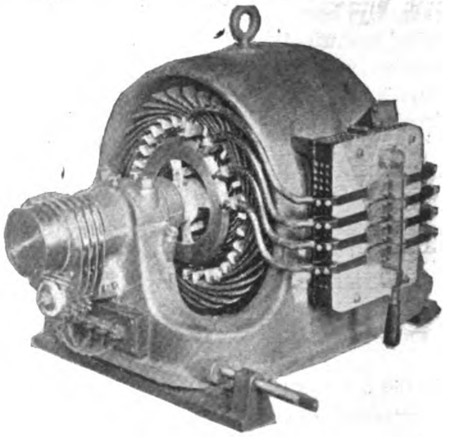

FIG. 3.—TESLA 50 H. P. TWO-PHASE MOTOR. OLD STYLE SWITCH. NEW STYLE COLLECTOR BRUSHES.

hammers for copper forging, in the blacksmith shop, every piece of machinery in the establishment is electrically driven.

THE WAREHOUSE.

Directly south of the machine shop is a building of equal length, but only 76 feet 2 inches broad, whose entire first floor is occupied as a warehouse, in which all finished and returned material is stored for further disposal. For the handling of this material there are two 10 ton electric cranes with runways extending the entire length of the building.

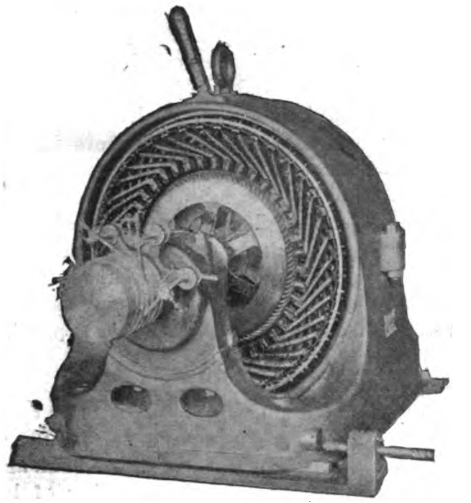

FIG. 4.—TESLA 50 H. P. TWO-PHASE MOTOR. NEW STYLE SWITCH RING. OLD STYLE COLLECTOR BRUSHES.

The second floor is connected by five bridges with the second floor of the south wing of the machine shop thus practically making the two one. The west end of this floor is devoted to the general offices of the administrative, engineering and draughting departments and the eastern end to the instrument department, including meter, arc lamp and switchboard equipments.

THE POWER HOUSE.

East of the warehouse, and separated from it by a passageway 52 feet wide, is the power house. This is 206 feet long by 76 feet 2 inches wide, and devoted in its western part to the engines and dynamos and two hand-operated overhead cranes and in its eastern part to the boilers. The latter are Pierpoint boilers of 2,500 h. p., and there is room for an equal number more. These boilers are equipped with the Roney mechanical stoker. The fuel is delivered from cars on an elevated track direct into large iron hoppers from which it descends as needed to the grates without manual handling of any sort. The present engine and dynamo equipment consists of two 500 h. p. Westinghouse compound engines directly connected by means of two standard Westinghouse flexible couplings to two 500 h. p. two-phase Tesla generators, and two similar engines connected in the same way to two 500 volt multipolar direct current generators. The foundations are all ready for one more 500 h. p. unit of each kind.

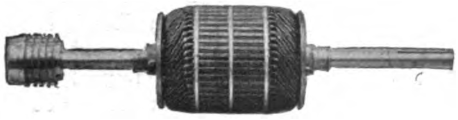

FIG. 5.—TESLA 10 H. P. MOTOR. ROTATING PRIMARY.

PUNCH SHOP.

Fifty feet to the east of the power house and on the same lines is the punch shop, 258 feet long by 76 feet 2 inches wide. Upon the ground floor are the shearing and heavy punching machines, and storage for sheet iron. In the extreme east end are the annealing ovens. The second story is devoted exclusively to the machines for punching armature disks, converter and other shapes for laminated structures.

Running along the north fronts of the warehouse, power house and punch shop is a surface railroad track connecting with the Pennsylvania Railroad's main line, and along the south walls an elevated track by which shipments to and from the second stories of the buildings are made.

TEMPORARY BRASS FOUNDRY.

Just north of the punch shop is a one-story corrugated iron building, 40 feet by 242 feet, used as a brass foundry, and north of this is the

BLACKSMITH SHOP.

This is a substantial brick building covering an area of 242 feet by 82 feet 6 inches. These last three buildings complete the extreme eastern tier of buildings, as do the machine shop and warehouse the western.

Through the center of the building runs a track for local transportation purposes. There are already erected and in operation within this building twenty-five forge fires, and there are fifteen more to be installed. The blast for these forges is supplied by two 10 h. p. two-phase motors. Over each fire is suspended a large sheet-iron hood to collect the smoke and other products of combustion, and these are connected with a system of flues in which a strong draft is created by exhaust fans operated by two 20 h. p. Tesla motors. There are also two large Allstatter combined shears and punches and some smaller tools operated by one 20 h. p. motor. Besides these there are three small steam hammers for forging copper bars of the largest size used in dynamo construction.

CARPENTER SHOP.

The carpenter shop, 60 by 192 feet, lying east of the machine shop, is a one-story corrugated iron building, fully equipped for the purpose. In the 65 feet space separating the machine shop from the warehouse is located the

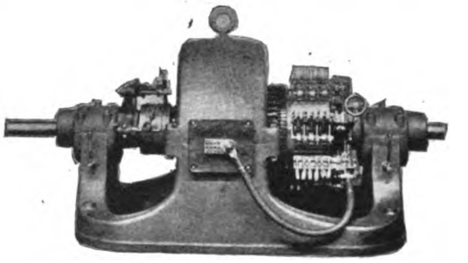

FIG. 6.—TESLA ROTARY TRANSFORMER.

COIL-BAKING AND OIL STORAGE HOUSE,

which is a small brick building, 182 feet 10 inches long by 27 feet 4 inches wide, devoted to the purposes indicated in its name. On the roof of this has been constructed a light, airy room in which the thousands of blue prints used by this great establishment are prepared.

(To be continued.)

Personal.

Mr. W. A. Stadelman, a gentleman who is pleasantly remembered by a good many people in the trade through his former connection with the Sprague Company, is now established in the Havemeyer Building as New York agent for the Elwell-Parker Company and the Brown Hoisting and Conveying Company of Cleveland. These companies have a first-class line of apparatus to offer the public, and we look for a large increase in their business through the New York office. Mr. Stadelman, it will be remembered, distinguished himself at the time of the Cape May Convention by saving from drowning a young lady who had been carried beyond the lines while in bathing.

Mr. J. H. Rhotehamel, president of the Columbia Incandescent Lamp Company, has been in the city for several days.

Mr. F. S. Terry of the Sunbeam Lamp Co., Chicago, is in New York this week.

A PIONEER IN ELECTRICITY:

Sir Francis Ronalds, F. R. S.

BY JOHN SYME.

[The following piece of history, originally published in our English contemporary, *Lightning* (September 1 and 8, 1892), has been republished in pamphlet form by Messrs. Simpkins, Marshall, Hamilton, Kent & Co., Limited, London, and will be of interest to those of our readers who have followed the articles already published in ELECTRICITY on the early history of the telegraph.—ED.]

Wheatstone and Cooke in England and Morse in the United States receive the popular honors, and in their generation received the substantial rewards due to men who first on the largest scale demonstrated to the public satisfaction the utility and practicability of the working of the electric telegraph. Their labors entitle them to honor. No material reward could ever adequately repay them for the benefits which they have conferred on humanity by their discoveries.

But many men of science, in patience, in humility, with many a vision floating before them of what was coming, had laboriously plowed and sowed in the field in which these distinguished and, as the world reckons it, more fortunate men ultimately reaped the harvest. The labors, successful experiments as well as failures, of these earlier workers are apt to be wholly forgotten; but they were none the less necessary in the evolution of the invention which long ago revolutionized modern commerce, which may be said to have created the modern newspaper, and which links together the nations of the world.

Of these pioneers, who for love of science devoted their lives to it, none more richly deserves a niche in the corner of the Temple of Fame devoted to electrical progress than the venerable man, Sir Francis Ronalds, F. R. S. Ronalds had not the practical businesslike qualities—what in common parlance is nowadays known as "push"—but a comparison of dates will clearly show that twenty years before Wheatstone and Cooke or Morse had patented their improvements in the telegraph, indeed while the first two were respectively lads of 12 and 14 years of age, Ronalds had sent messages over eight miles of overhead wire of his own construction, and had laid and worked a serviceable underground line of telegraph of sufficient length to demonstrate the practicability of communication by telegraph between long distances.

Details of the construction and working of these lines are given in an interesting and now somewhat rare little volume entitled "Descriptions of an Electrical Telegraph and of Some Other Electrical Apparatus," published in 1823—i. e., fourteen years before Wheatstone and Cooke patented the improvements with which their names are identified. Plates I and II are from the careful drawings which appear in that little volume illustrative of Ronalds's methods. The experimental line, overhead wires eight miles long, was erected in the year 1816 ("amid many scoffs and jeers and a few imputations of insanity," says Ronalds pathetically in a letter to a friend which now lies before me) in the garden of the house at Hammersmith now occupied by Mr. William Morris, the distinguished poet and well-known Socialist, the house being in 1816 occupied by Ronalds. Quite recently a plain tablet, or inscribed slab, commemorating the fact that in this garden the first message on any wire of really considerable length was successfully sent, has been placed with the consent of Mr. Morris on one of the walls of his house.

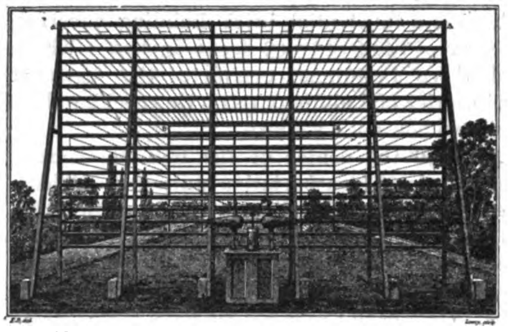
In Ronalds's essay, "Descriptions of an Electrical Telegraph," published in 1823 (and the date is important), he describes his overhead wire as follows: "Upon a lawn or grass-plot at Hammersmith I erected two strong frames of wood, A and B, Plate I, at the distance of twenty yards from each other, and each containing nineteen horizontal bars. To each bar were attached thirty-seven hooks, and to the hooks were applied as many silken cords, which supported a small iron wire (by these means well insulated), which (making its inflexions at the points of support) composed in one continuous length a distance of rather more than eight miles. When a Canton's pith ball electrometer was connected with each extremity of this wire, D and E, and it was charged by a Leyden jar, F, both electrometers appeared to diverge suddenly at the same moment; and when the wire was discharged, by being touched with the hand, both electrometers appeared to collapse as suddenly. . . . When the spark was compelled to pass through the gas pistols, C, and anyone closed his eyes, it was impossible to distinguish more than one explosion, although both pistols were discharged." He was thus able to demonstrate to three of the senses—sight, feeling and hearing—that through eight miles of wire there could be practically instantaneous transmission of electric signs. (See Plate I.)

His next step was to dig a trench in the same garden 525 feet long and 4 feet deep. "In this," again to quote his essay of 1823, "was laid a trough of wood, 2 inches square, well lined in the inside and out with pitch, and within this trough thick glass tubes were placed, through which the wire ran." Plate II, Fig. 1, shows a section of the trough, tubes and wire, from which it will be seen that the different lengths of tube did not touch each other, but that at each joint, or rather interval, other short tubes were placed, of just sufficient caliber to admit the ends of the long ones, together with a little soft wax, which effectually excluded any moisture from insinuating itself between them, and also allowed a little play or motion for the contraction and expansion which variations of temperature produced. For in the first attempts, when hard cement was used, the tubes were apt to break with changes of temperature. "The trough was then covered with pieces of wood, screwed upon it while the pitch was hot; they also were well covered with pitch, and the earth then thrown into the trench again."

His method of reciprocal communication was thus devised: "A light, circular brass plate, divided into twenty equal parts, was fixed upon the seconds-arbor of a clock which beat dead seconds. Each division was marked by a figure, a letter and a preparatory sign. The figures were divided into two series, from one to ten, and the letters were arranged alphabetically, leaving out J, Q, U, W, X and Z. Before or over this disk was fixed another brass plate . . . which had an aperture of such dimensions that, whilst the other disk was carried round by the motion of the clock, only one of the signs upon it could be seen through the aperture at the same time. In front of this pair of plates was suspended an electrometer of Canton's pith balls from a wire which was insulated, communicating with a cylindric electrical machine of only six inches diameter and with the above described buried wire." A second electrometer and clock were placed at the other end of the buried wire adjusted to go as nearly as possible synchronically with the first. "When the wire was charged by the machine at either end the electrometers at both ends diverged; when it was discharged suddenly at either station they both collapsed at the same instant; and when it was discharged at the moment when a given letter, figure and sign on the lower plate of one clock appeared in view through the aperture, the same figure, letter and sign appeared also in view at the other clock; and that by such discharges of the wire at one station, and by noting down the letters, figures or signs in view at the other, any required words could be spelt and figures transmitted."

Ronalds thereafter proceeds to suggest a code or telegraphic dictionary of great ingenuity to economize both time and discharges; and suggested sundry methods by which injury to a damaged wire could be successfully and readily located.

Much of the essay is occupied with popular objections to the introduction of the telegraph, difficulties which experience long ago has proved to be baseless. One objection in these early days frequently raised was the liability of the subterranean wires to be injured by an enemy or by mischievously disposed persons. After considering various practical methods of meeting this danger Ronalds quaintly says: "If they still succeed in breaking the communication by these means, hang them if you can catch them, damn them if you cannot, and mend it immediately in both cases."



A and B: Strong frames of wood erected in 1816 in Ronalds' garden, twenty yards apart; nineteen horizontal bars, supporting eight miles of insulated wire. C: Two air pistols. D and E: Extremities of wire. F: Leyden jar

PLATE I.

He also in this essay predicts with extraordinary foresight the immeasurable public utility to which the electric telegraph may be applied. "Why should not our kings hold councils at Brighton with their ministers in London? Why should not our Government govern at Portsmouth almost as promptly as in Downing Street? Why should our defaulters escape by default of our foggy climate? Let us have electrical conversazione offices communicating with each other all over the kingdom."

This, it must be remembered, was written when the sprawling arms of the semaphore were the swiftest messengers of news in public use, however urgent the occasion.

One of the stations of this garden line of wire (the longest, if not actually the first which up to that time had been seen in England) was situated in a room over Ronalds's stable, and the other at the end of the garden in a tool-house. The wire was buried under the gravel walk. Nearly half a century later there was dug up in the Hammersmith garden several yards of copper wire, a glass tube with the copper wire in it, and one of the joints with a short glass tube; the wooden trough and pitch had become almost as hard as drain-tile. It seems a pity that this interesting relic, which on being found was placed in the Pavilion Museum at Brighton and was later in the possession of Mr. L. Clark, M. I. C. E., along with the original dial-plates used by Ronalds, both of which were procurable, did not find a place on the stand devoted to historic relics of the progress of the science at the Electrical Exhibition at the Crystal Palace in 1892. Ronalds's wire and dial-plates were in active work, as we have said, in 1816; whereas the earliest exhibit at the Crystal Palace was Cooke and Wheatstone's needle instrument of 1837.

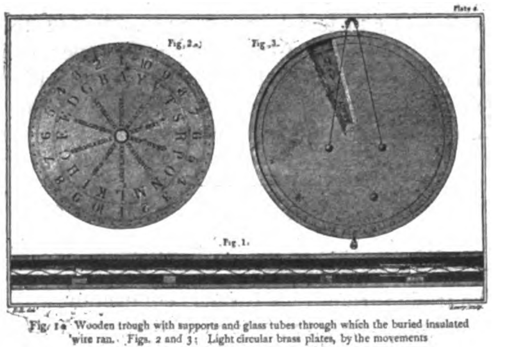


Fig. 1: Wooden trough with supports and glass tubes through which the buried insulated wire ran. Figs. 2 and 3: Light circular brass plates, by the movements of which messages were read.

PLATE II.

The most advanced ideas in science of one generation often become the commonplaces of the next. Sir F. Ronalds's methods have been, of course, greatly improved by his successors in the same field, but to him belongs the honor of being one of the most noteworthy pioneers in the science that, since his early labors, has revolutionized modern life.

His experimental eight-mile overhead wire and his underground telegraph had proved not merely the possibility but the practicability of sending messages over long distances as early as 1816; while Wheatstone and Cooke's apparatus was not patented until 1837.

It is rather a curious fact that Sir W. F. Cooke's father was a surgeon living at Brentford at the date of Ronalds's residence and experiments at Hammersmith, and that Ronalds showed him and explained minutely to him the working of his telegraph. In the controversy which sprung up between Cooke and Wheatstone in 1854 as to the invention of the electric telegraph, Wheatstone says: "Mr. Cooke's principle (the principle of reciprocal communication) was no novelty, . . . having been developed completely and effectively by Mr. Ronalds in his telegraph, the description of which was published as early as 1823." There is good evidence also that Wheatstone himself as a lad of 15 was present at some of the principal experiments in the garden at Hammersmith.

It is not, of course, here sought to assert that Cooke and Wheatstone were not men of great original ability and deserved the honor which they lived to enjoy in connection with their labors, but it is contended that Ronalds paved the way for them. His ideas were in the atmosphere. Ronalds described his invention, as we have stated, but he never took out a patent. It was not until 1837 that a patent was granted to Wheatstone and Cooke for "improvements in giving signals and for sounding alarms in distant places by means of electric currents transmitted through metallic circuits."

England's most rapid method of getting public news from distant places in the days while Ronalds was quietly at work in the Hammersmith garden, was, as I have said, by the semaphore, an arrangement at once costly and clumsy. In fogs, and at night, no communication could be sent. Mr. Frost, librarian to the Society of Telegraph Engineers, states that during three years the semaphore from the Admiralty could not be used, owing to atmospheric disturbances, on 323 days, and that the annual cost for the working of the semaphore between London and Portsmouth alone was £2,000.

Ronalds, conscious of the public importance of his invention, offered it to the Government of the day. Mr. Frost, in his short sketch of Ronalds which forms the introduction to the Ronalds Library Catalogue, publishes the correspondence. It is certainly interesting and instructive, giving a little insight, on the one hand, to the character of Ronalds, and, on the other, a glimpse of the crass dullness and incapacity of the official mind to grasp the fact that the world is moving.

Ronalds sent the following note to Lord Melville, then First Lord of the Admiralty:

> "Mr. Ronalds presents his respectful compliments to Lord Melville, and takes the liberty of soliciting his Lordship's attention to a mode of conveying telegraphic intelligence with great rapidity, accuracy and certainty, in all states of the atmosphere, either at night or in the day, and

at small expense, which has occurred to him whilst pursuing some electrical experiments. Having been at some pains to ascertain the practicability of the scheme, it appears to Mr. Ronalds and to a few gentlemen by whom it has been examined, to possess several important advantages over any species of telegraph hitherto invented, and he would be much gratified by an opportunity of demonstrating those advantages to Lord Melville by an experiment which he has no doubt would be deemed decisive, if it should be perfectly agreeable and consistent with his Lordship's engagements to honor Mr. Ronalds with a call; or he would be very happy to explain more particularly the nature of the contrivance if Lord Melville could conveniently oblige him by appointing an interview.

"Upper Mall, Hammersmith, July 11, 1816."

At first Lord Melville seemed disposed to grant an interview—indeed made an appointment; but ultimately Ronalds received the following letter from the Secretary of the Admiralty:

"Mr. Barrow presents his compliments to Mr. Ronalds, and acquaints him with reference to his note of the 3d inst. that telegraphs of any kind are now wholly unnecessary, and that no other than the one now in use will be adopted.

"Admiralty Office, 5th August, 1816."

If any individualist desires an argument to hurl at the head of a Socialist opponent here is one ready to his hand. Yet Mr. Barrow (afterwards Sir John) lived to write the article on "Telegraphs" in an edition of the "Encyclopædia Britannica."

The immediate result of the correspondence was to throw back research and experiment of electrical science in England for twenty years, and to deprive the nation of the benefits of the invention for that period. Ronalds had to endure the disappointment of most men who are twenty years ahead of their generation.

In 1842 he was appointed superintendent and director of the Kew Observatory under the auspices of the British Association. During this period he invented many important instruments which have had direct and important bearing on electro-meteorological science. His labors in this direction have their place in the Philosophical Transactions of the Royal Society and in the Reports of the British Association.

In 1844 he was elected a Fellow of the Royal Society. The following extract from his will is thoroughly characteristic of the generosity and fine sense of honor of the man:

"I bequeath to the President, Council and Fellows of the Royal Society the sum of £500, in trust, for the augmentation of the Wollaston Fund, and in recognition of the advantages I derived when Honorary Director of the Kew Observatory from grants which I received from that Fund in aid of my not unsuccessful inventions of photographic instruments for the registration of terrestrial magnetism, atmospheric electricity and other meteorological phenomena."

It was not until Ronalds had reached his 83d year, on the recommendation of Mr. Gladstone, that the tardy honor of knighthood was conferred on him "in acknowledgment," as Mr. Gladstone wrote, "of his early and remarkable labors in telegraphic investigations."

To the Society of Telegraph Engineers he bequeathed a fine library of rare, curious and valuable books, collected all over Europe during his long life, of works bearing on electricity, magnetism and the electric telegraph, and with this collection Mr. Frost tells us that among other unpublished MSS. he has left the heads of a proposed "History of Electricity," which it is to be hoped will yet see the light. His book entitled "Descriptions of an Electrical Telegraph" (1823), the first edition of which is now scarce, from which I have quoted, is particularly interesting as being, I believe, the first English book on the electric telegraph.

Ronalds was a man of great originality, whose modesty, amounting to diffidence, did much to hide his real merit from the world. Had he been a pushing, thick-skinned man of business, doubtless the public monuments and the material fortune that many men who have done less for science have attained would have been his. He was content to do his share of the world's work quietly, modestly, and with a single eye to the promotion of scientific knowledge without regard to any personal rewards. Such men deserve to be honorably remembered when the history of any great movement comes to be recorded.

ELECTRIC CURRENTS OF HIGH PRESSURE AND PERIODICITY.*

BY A. A. C. SWINTON.

The experimental effects that I propose to show this afternoon are all produced by utilizing the disruptive discharges of Leyden jars to give electrical impulses of comparatively considerable magnitude as regards energy but of exceedingly short duration as regards time.

As is well known, if a Leyden jar be discharged through a stout copper wire forming a circuit of small resistance, a surging of the electrical charge is set up, with the result that the electric current which passes through the wire is of the nature of a gradually dying-away oscillation. The action may, indeed, be compared to what occurs when a pendulum, immersed in some viscous fluid, is suddenly released from an inclined position and swings backwards and forwards with a gradually decreasing amplitude of oscillation until it comes to rest; or we may make the analogy more exact by comparing the effect to a loaded spring bent aside in a resisting medium and then let go. The pliability of the spring corresponds to the capacity of the condenser, its displacement to the electrical charge, the load or inertia to the self-induction of the circuit, and the viscosity of the fluid to the resistance of the circuit.

Thus the total duration of the discharge of a Leyden jar varies with its electrostatic capacity, being longer for large jars than for small. At the same time, both the duration of the discharge and the rate of oscillation are dependent upon the resistance and self-induction of the discharging circuit. In apparatus of the kind that we employ the conditions are exceedingly complex, and consequently calculations as to the duration of the discharge, or as to its rate of oscillation, must necessarily be only approximate. The total duration of the discharge itself can, however, be fairly accurately measured experimentally by means of a revolving mirror, and I think you may take it as tolerably correct when I tell you that the total duration of each discharge of the batteries of Leyden jars that we have here, and are going to use, is about $\frac{1}{50000}$ of a second. It has been further calculated that, with the conditions that we are working under, the rate of oscillation should be about 200,000 complete periods per second, so that apparently we get about four complete oscillations in each of our discharges.

Our jars are charged by means of an alternate-current dynamo machine, which has a frequency of approximately 100 complete alternations per second. The jars are charged and discharged at each half-period, consequently one in each $\frac{1}{200}$ of a second. The duration of the discharge is, as already mentioned, $\frac{1}{50000}$ of a second, and consequently, if we devote our attention merely to what is taking place in the discharging circuit, there are intervals between each discharge of $\frac{249}{50000}$ of a second, during which intervals there is no current passing at all.

Fig. 1 shows this from a diagrammatic point of view. Only four discharges are shown, and it has unfortunately not been possible to show the intervals between them to scale, as, if shown on the same scale as the discharges, each of which on the diagram occupies 10 inches, the intervals ought to be no less than 208 feet.

It has been usual to call oscillatory currents produced in this manner "high frequency" or "high periodicity electric currents." I am not sure with whom the term originated, but I think it was with Mr. Tesla, to whose investigations in this particular branch of electrical science we all owe so much. I am bound to say, however, that the term seems to me to be a very unfortunate one, as though the periodicity is decidedly high during each discharge, the discharges are of so very short duration, and are spaced by such comparatively long intervals, that the average frequency is really not high at all; in fact, in the experiments I am about to show you, the average frequency appears only to be about 800 a second as against 100 a second, the periodicity of the alternator supplying the original current.

Further—and what I am now going to say is, I believe, in direct contradiction to the orthodox view—it does not appear to me that any high frequency at all is necessary to explain the effects produced. All that is necessary is that the electric current should be delivered in impulses of exceedingly short duration, in which the current and voltage rise from zero to enormously high maxima, and fall again to zero with exceeding suddenness. The defects are, in fact, due to the rapid rate of change.

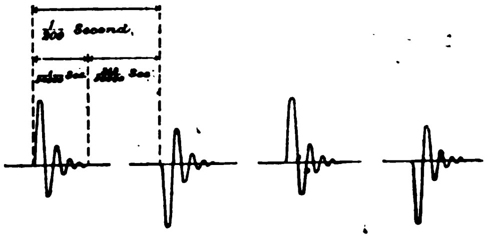

FIG. 1.

Now, oscillatory or pulsatory currents of the description that I have mentioned behave in many respects in quite a different manner from continuous or ordinary alternating currents. This is due to the fact that while with ordinary alternating currents the effects of impedence, induction and electrostatic capacity are comparatively small, unless we take special means to render them operative, with our oscillatory currents these effects are comparatively enormous, and show themselves whether we will or not.

To take first of all the case of impedence. We have here a thick copper wire bent into a U-shape, which would conduct an ordinary alternating current with practically no impedence at all. We have it connected, as shown in Fig. 2. We start with a 100-volt alternating current of the ordinary description, which passes through the primary of an induction coil. From the secondary of this coil we obtain some 20,000 to 30,000 volts. This high pressure current charges the Leyden jars at each half-period up to a point where the air resistance across the spark gap is broken down, and a disruptive oscillatory discharge takes place. In this manner we obtain an oscillatory discharge of electricity through our U-shaped piece of copper wire. In order to let you see the effect of the impedence, I will connect these incandescent lamps across from one leg to the other of the U-shaped wire. You will observe that though short-circuited by the wire, which has enormously less ohmic resistance than the lamp filaments, the latter incandesce brightly. The oscillatory current, in fact, does not take the path of least ohmic resistance, as might be expected, but the shortest path—i. e., that of least self-induction and impedence. By sliding the lamps up and down we can make them burn more or less brightly, and by choosing suitable positions we can make lamps varying in voltage from 20 to 100 volts all burn with uniform brightness.

---

* Contribution to the Professional *Papers* of the Corps of Royal Engineers, Chatham, Eng.

Again, oscillatory electric currents such as those with which we are dealing have much more powerful inductive effects than ordinary alternating currents.

We have here two circles, each consisting of a single convolution of thick copper wire. One of these circles has a 20-volt 5 C. P. incandescent lamp connected to the two ends of the wire, and the other circle is connected as was the U-shaped wire in the last experiment, so that we can send oscillatory discharges through it. We will hold the two circles facing one another about 6 feet apart and turn on the current. As you see, the lamp filament is gradually becoming red hot, showing that the oscillatory current passing through the one circle is inducing an electric current in the other. If we bring the circles nearer together the light becomes brighter, and with an interval of 2 feet the lamp is fully incandesced.

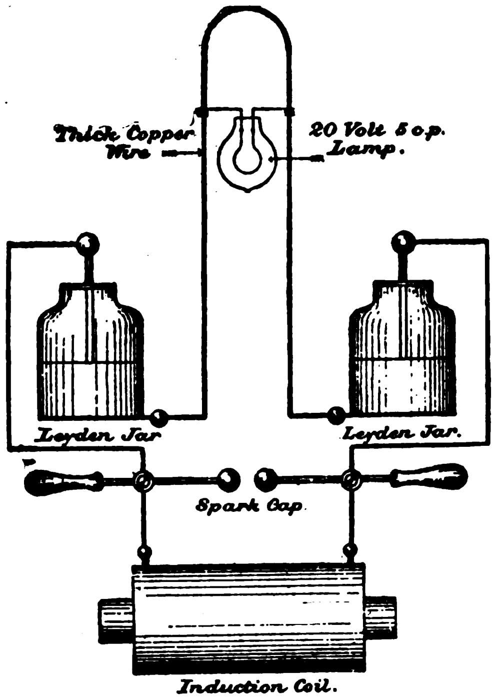

FIG. 2.

One of the most striking facts in connection with these oscillatory currents is the small physiological effect that they appear to have on the human frame. As is well known, the discharge of a good-sized Leyden jar, if taken direct, occasions a most violent shock to the system, and may, indeed, be sufficient to destroy consciousness for a time, or even to cause death. The current from a medical magneto machine, or even a small induction coil, is sufficiently unpleasant for most people, while that from an alternate current dynamo giving 1,000 to 2,000 volts is used for official electrocution in the United States of America, and has been the cause of more than one death in this country. The electric currents employed in medicine rarely exceed a few thousandths of an ampere, muscular fixation and other unpleasant results being usually produced when more than 10 to 20 milliamperes of continuous, or two to six milliamperes of alternating or interrupted, current is passed through the body.

We have here an ordinary 5 C. P. 100-volt lamp, which, with continuous or ordinary alternating current, requires about one-fifth of an ampere or 200 milliamperes to bring it to full incandescence. This is, of course a much greater strength of ordinary current than anyone could bear for a moment. We will incandesce this lamp with current conveyed through the bodies of two persons. The connections are as shown in Fig. 3, and as you will observe, there is no connection between the lamp and the other apparatus except through the arms and bodies of the two operators. As you will see, the lamp filament is brought up to full incandescence when we turn on the current.

Various theories have been propounded to account for the harmlessness of these currents. Some have supposed that the human body acts not as a conductor, but like a condenser with regard to the passage of alternate currents, forgetting that were this the case the impedence offered to oscillatory currents would be very small, and the application of high voltages, such as I have been using, would consequently be serious. Some, on the other hand, have imagined that it is all a question of the nerves, which they assume to be, as it were, tuned only to respond to alternations of comparatively low periodicity, and being unaffected by those above a certain range, as is the eye to luminous waves above the frequency of violet light.

The real facts of the case seem to be that wherever these oscillatory currents are harmless it is simply for the reason that the quantity of electricity they transmit in any given time is too small to do any injury. Leaving on one side those physiological effects from which the burning and disruptive action produced in the tissues traversed are clearly due to the internal production of considerable quantities of heat, the physiological effects of electric currents seem most probably to be due to chemical decomposition—in fact, to electrolysis. Now the amount of electrolytic effect in any given time is, of course, proportional to the quantity of electricity—that is to say, to the number of the coulombs passed in that time. What, therefore, can be more natural than that the physiological effects of electric currents should, within limits, be proportional to the coulombs of electricity passed.

It will, however, be said that in the lamp experiment I have just shown you the current in the lamp must have been one-fifth of an ampere, and that, consequently, whatever the description of the electric current—continuous, alternating, or oscillatory—one-fifth of a coulomb was passed through the arms and bodies of the operators during each second that the lamp was lighted.

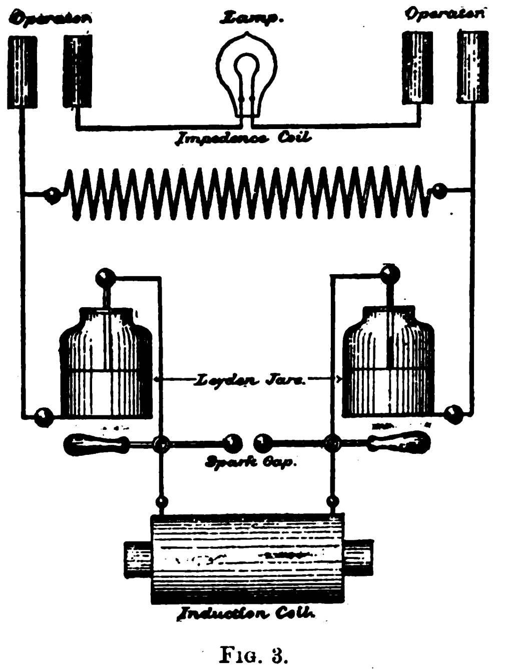

FIG. 3.

A little consideration will, however, show that this is by no means the case. In the first place, as has been shown by Lord Kelvin, oscillatory currents which rise and fall between minimum and maximum very rapidly do not flow uniformly through the section of a conductor. They tend to keep on the surface, and given sufficiently sudden fluctuations, may only be, as it were, skin deep. Applying this to the filament of our lamp the effect is to increase its resistance, since only a part of the section of the filament acts as a conductor. The filament might, in fact, be a hollow tube instead of a solid wire. We have ample sufficiency of available voltage, and though the strength of the current may be small, the resistance being high there is a sufficient expenditure of watts to raise the filament to incandescence. The lamp, in fact, ceases to be a 100-volt lamp taking one-fifth of an ampere, and becomes, may be, a 1,000-volt or even a 10,000-volt lamp, taking only a tenth or a hundredth of that amount of current.

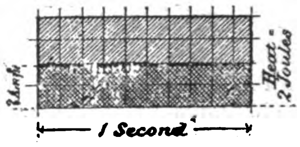

FIG. 4.

Steady Current.—Assumed resistance equals 1 ohm; assumed quantity, 2 coulombs; time equals 1 second; ∴ current equals 2 amperes; ∴ heat generated equals 2 joules.

There is also another point to be borne in mind. The current is delivered in impulses of exceedingly short duration. If we turn to Fig. 4, the double-cross shaded portion of the figure represents a current of two amperes flowing for one second of time. The area of this portion thus represents two coulombs of electricity. If we assume that this current is being passed through a resistance of one ohm, the heat generated in the resistance will clearly be equal to two joules. So much for continuous current. If we now turn to Fig. 5, we have a similar quantity of electricity—namely, two coulombs—passed through a similar resistance of one ohm; but instead of sending the current through continuously for one second, we will suppose it to be sent through in four pulsations, each lasting for one-tenth of a second, with intervening spaces of one-fifth of a second of no current at all. In order to pass our two coulombs within the second under these conditions, the average current during each pulsation will have to flow at the rate of five amperes, and the amount of heat generated, being proportionate to the square of the current, will be one and a quarter joules for each pulsation. The total heat generated during the second will, therefore, be equal to five joules, as against the two joules generated when we employ a steady current. Conversely, of course, the same quantity of heat can be generated in a given resistance and in any given time with a pulsating current with a less quantity of electricity than will generate this quantity of heat in the same

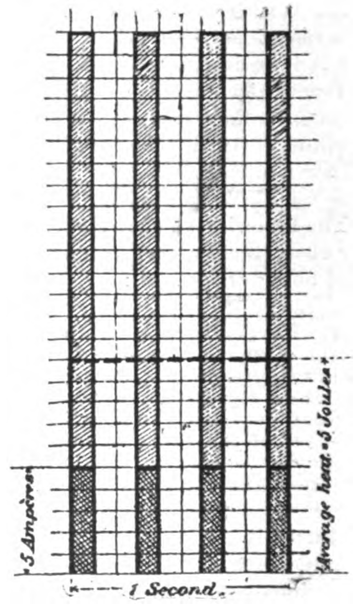

FIG. 5.

Pulsating Current.—Assumed resistance equals 1 ohm; assumed quantity equals 2 coulombs; total time equals 1 second; duration of each pulsation, one-tenth second; then average current during each pulsation equals 5 amperes, and heat generated equals 5 joules.

time with a steady current. Further, the shorter the duration of the impulses the smaller is the quantity of electricity necessary, so that when we come to impulses of such exceedingly short duration as $\frac{1}{50000}$ of a second, such as we have been using in our experiments, the quantity of electricity necessary to produce the amount of heat required to incandesce our 5 C. P. lamp must be exceedingly small indeed.

So far we have been dealing with what I may term "primary oscillatory currents"—namely currents that are derived directly from the Leyden jars without transformation. We will now try the effect of a step-up transformer which is contained in this box, and is entirely immersed in resin oil, in order to prevent sparking and the dissipation of energy by leakage either in the shape of conduction or brush discharges. The arrangement of the connections may be shown in Fig. 6.

We are now dealing with oscillatory discharges having a potential difference that may be measured in hundreds of thousands of volts, and, as you will notice when the light is put out, the brush discharge effects are very striking. If I present my hand to one of the terminals of the coil sparks shoot out to my fingers. These sparks cause a painful pricking, but if I take a piece of metal in my hand and present it to the terminal I can take a violent discharge of sparks practically without any sensation. If I take hold of one terminal of the coil with one hand, which I can do without hurt, and present the other hand to the outside of the box of oil containing the coil, streams of sparks issue from my finger tips. Again, having hold of one terminal I can draw sparks from any body having electrostatic capacity, such as another person or any metallic body, merely by bringing my free hand, or for that matter my foot or any part of my body, near to them.

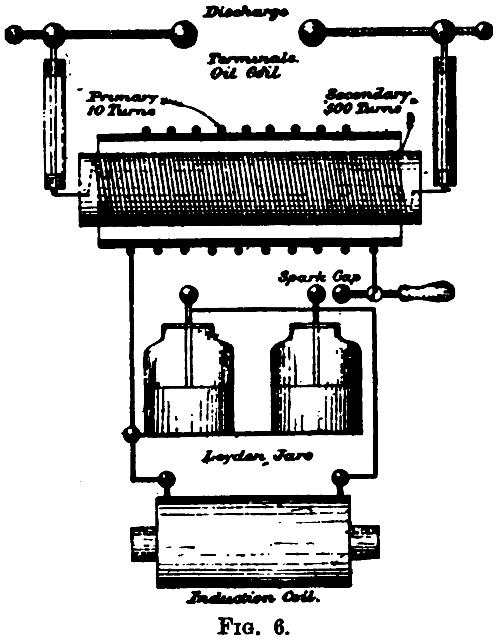

FIG. 6.

The high-tension oscillations have also marked electrostatic inductive effects. We will show this by attaching a tin-plate to each of the two terminals of the coil. We have here two other tin-plates, between which an incandescent lamp is connected. When we bring these latter plates within a foot or 6 inches of the others, the lamp incandesces brightly. We can also incandesce a lamp filament by connecting one lamp terminal to one coil terminal and merely touching the other lamp terminal with a piece of metal held in the hand. The operator can stand upon an insulated stool, it makes no difference, as the effect is due not to any circuit being established, but to the electrostatic capacity of the operator's body. The electricity in fact merely runs in and out of the operator through the lamp, and thereby incandesces the latter.

Pretty effects can be shown by passing the high-tension discharge through a piece of wood, the sparks finding their way through the substance of the material, and lighting it up with a dark red color. Or a piece of glass, one side of which is covered with tinfoil, may be placed between points connected to the terminals of the coil. As will be seen, the discharge spreads out in fiery streamers over the glass with a loud roar. By substituting a dry photographic plate for the glass we can obtain photographs of the discharge taken with its own light. I have had lantern slides made of photographs produced in this manner, and, as you will see, they give very beautiful effects. The figures produced by positive electricity are irregular, somewhat resembling the rivers on maps. Those produced by negative electricity are, on the other hand, beautifully curved, and are like feathers or palm branches. Oscillatory discharges show both positive and negative figures combined.

The oscillatory electrostatic stresses set up in the neighborhood of the coil will also produce luminosity in vacuum tubes. If I wave the tubes rapidly you will notice the discontinuity of the light, which is due to the intervals of time between the succeeding groups of oscillations. I have here a cylindrical vacuum tube, outside of which is wound a few turns of thin wire in the form of an open spiral. I connect one end of this wire to one terminal of the coil, and you see two luminous spirals twisting in and out of each other. One is the wire, which glows with a dark purple color, the other is a species of ghost produced by molecular bombardment inside the tube.

The luminosity of wires can, however, be shown on a larger scale. We have here two circles of wire, a large and a small one. We will connect them respectively to the two terminals of the coil, and place them concentrically in one plane. When we switch on the current and lower the gas you will see that both wires glow brightly, while the interval between them is filled with streamers of purple light; or we can connect these two parallel wires which reach to the other end of the lecture hall, and which become luminous throughout their entire length.

These are all the experiments I have to show to you this afternoon. These phenomena may not in themselves have any immediate useful application, but they are in many ways very instructive. In addition, the essence of science is the correlation of facts, and the further we pry into the secrets of nature the more we are likely to achieve useful results.

A Chicago inventor has devised a mail-carrying arrangement which has favorably impressed the postal authorities, and if successful will do away with the lumbering mail wagons in city streets, as mail will be carried on trolley cars running on wire cables strung over the roofs of houses. A test will be made in Chicago at an early day, the city council having granted the inventor permission to string his wires. The cost of construction is put at $250 a mile. A description of the motor and carrier by the inventor is as follows: "The whole arrangement weighs 32 pounds. The motor alone weighs 18 pounds and its strength is ¼ horse-power as proved by actual tests. It will be operated by a single wire without a return circuit. All parts of the carrier except the motors are made of aluminum. The cars are detachable from the frame, and can be taken out and changed in ten seconds. The motors will climb an incline of 20 per cent. The speed is regulated before the carrier is started on its trip by a simple attachment. It will run no faster down grade than up. It cannot jump off the wire even at a speed of 100 miles an hour. It runs on a four-inch sheave wheel with deep flanges. The wheel is furnished with ball-bearings. The power required to operate the carriers at a speed of 60 miles an hour is exactly the same as is required to run an ordinary arc light. A current of 110 volts is used. A heavier cable is used than is necessary to sustain the weight as a measure of safety."

Notes on Recent Electrical Engineering Developments in France and England*—III.

DISCUSSION.—(*Continued*).

The President—I will call now on Mr. Leonard to close this discussion.

Mr. Leonard—I have so many points to answer that I hardly know where to begin. If I inadvertently embraced far more in the scope of my paper as regards central stations abroad than I should have done, I regret it, and I can see upon reflection that there is cause for criticism if I have made remarks that are so sweeping as to involve stations which I did not see. In saying that undoubtedly we have the best three-wire central station plants in the world, I judged largely by my familiarity with those in this country by observation, and those abroad which I have not seen, by published descriptions. But one point which I wish to mention is, that I do not consider that any conclusions can be arrived at in judging the matter by the question of how many watts are delivered to the customer per pound of coal. The coal in the cost of the central station energy is less than 10 per cent.. It may possibly be that such stations abroad may show better results than ours as judged by the statistics compiled by the National Electric Light Association. But I hardly think this would necessarily be a criterion either, because we all know the care with which statistics are prepared by foreigners, and especially Germans, and we also, most of us, would be inclined to doubt whether all of the best of our United States stations had submitted full, detailed and accurate figures as to their production to the committee that published the results in question. There are a great many points concerned in what I would consider the best three wire plants which are not at all covered nor rubbed out by the question of the watts produced per pound of coal, and among them are the question of the perfection of distribution of pressure, the question of kilowatt hours produced per annum, per dollar of capitalization, and especially the question of how much earnings the station is making per dollar of investment, in which latter two points I am quite confident, although I have not the figures to back up the statement, that we are ahead of the European practice. I was very much surprised to hear one of the speakers state that the load factor of the New York Edison central station was 34 per cent., and I am almost forced to conclude that we differ as to the definition of load factor, for I had occasion personally to secure unquestionable returns in 1890 from the central stations in Chicago, Brooklyn, New York, Philadelphia and Boston, and at that time those stations averaged about 40 per cent. for the load factor and the New York station was the best of the lot, and I can only explain any such falling off as is represented by the present low factor of 34 per cent. as due to the taking on of too many of those fluctuating loads like elevators. As regards the question of the load factor again, I happened to be with the president of the Chicago Edison Company on my visit abroad, and while there he received complete statistics from Chicago in regard to the operation in December, and the load factor there during December was over 50 per cent. The speaker perhaps did not understand that my remarks were limited as regards the quotation as to the load factor in London in the month of December, in which, of course, the load factor is higher than would be ordinarily the case.

Another speaker spoke of 28 pounds per kilowatt hour not being correct relative to 15.7 pounds per indicated horse-power hour. I think these figures will bear scrutiny, and I call attention to the fact that the first one was in feed water per kilowatt hour in useful electric energy and not horse-power hour, and the second is per indicated horse-power hour.

As to the argument which has been presented by more than one, that while the Heilmann locomotive has a larger boiler there is no reason why similarly a steam locomotive should not have a larger boiler, I beg to say that while I do not profess to have any very great amount of knowledge on that subject, I have given some considerable attention to it of late, and have noticed the comments and the writings of a good many persons who claim to be very well versed, and apparently are, judging by their papers and by their standing, and the impression that I have derived is that there has been reached, very closely, a limit in the size of the steam locomotive boilers, that to make and place a larger boiler upon a locomotive to-day leads to such difficulties in many other ways as to be practically prohibitive, and I can only wonder, if they can run with a steam boiler sufficiently large, why they burn twice as much coal as we do with stationary boilers. There seems to be no question that they do burn more coal to produce a horse-power, and it is due to the fact that they do have too small a boiler and crowd it too hard. If they can, why don't they put on a bigger boiler ?

---

* H. Ward Leonard's paper read at a meeting of the A. I. E. E., February 27.

As to the cost of batteries, engines, etc., relative to each other, the figure of $107 per kilowatt, I think it is quite close to the mark of present practice, and I will say that in discussing this question with one of the best posted men in England, after considerable argument and figuring on his part, he stated that the cost of batteries, such as they made, would be $175 per kilowatt. As to the cost of engines, boilers and generators, I am satisfied if any such figure as $100 per horse-power has been quoted, that it must have been intended not to cover the boiler, engine and dynamo merely, but possibly the value of the real estate and buildings, etc., which they represent also, and which I have not included in my figures, as there is no doubt but that large boilers, engines and dynamos can be procured, not only at $50, but I believe at considerably less per kilowatt.

A criticism was made as to the suggestion of placing the batteries upon the consumer's premises instead of in the station. I think the speaker has lost sight of the fact that the only argument in favor of placing the battery in the position which I suggested was to enable the customer to obviate the necessity of calling upon the central station for those large spurts of energy which he required, with its consequent high cost, due to small load factor, at the rates I named. Placing the batteries in the central station would not correct the disturbance of lights or the drop in the conductors affecting other consumers, nor could the station afford to give to the customer such a low rate when these variations in the customer's load are still in existence as he could if it was a constant current supplied to that customer for twenty-four hours per day. I must say that knowing the general views of American central station managers about storage batteries, I thought it would be rather in consonance with their ideas if they could get a customer to buy the batteries and maintain them.

As to the $300 per kilowatt, that $300 per kilowatt represents not, of course, merely the boilers, engines and dynamos, but it represents the underground system which is very expensive per kilowatt, also the real estate and buildings, and possibly the usual percentage for the franchise, patents, etc.

I had no intention of impressing my hearers with the idea that the European practice was ahead of ours at the present moment. In fact, my opening clause stated that I was in doubt as regards the matter. But I did point out that they were making more progress than we were in this country in trying new methods, new apparatus and new combinations, diverging from the old beaten paths; and I consider that practice due to the fact that there are so many concerns over there which are considered first class and are almost always in any competition which arises. In this country when a large central station plant is to be installed, as we all know, it is not competed for by 25 or 30 concerns the majority of whom are engineers who understand the entire construction of the work and manufacture the apparatus in addition, but generally the plants are built by the people themselves, by some one of their employes, merely purchasing the apparatus from some one or two or three manufacturing concerns.

As to the question of dynamos and motors and the argument that we have, as I thought, better dynamos and motors than they have abroad, I can only say that I think the best reason for this is that there are no patents on them which even the smallest concerns are afraid of, and therefore we do have active competition from the smaller concerns which do not have large capitalization due to patents and heavy fixed charges, which necessitate the large profits of corporations such as I was commenting on.

The point as to the batteries not having been properly estimated by the fact that three and one-tenth watts was assumed, is not correct. The lamps were assumed at three and one-half watts per candle. Even if for the sake of argument it be assumed that the battery will cost $80 or $90 per kilowatt as against $50 for engine and boilers and dynamos, it would not affect the conclusion materially.

The argument was advanced that we ought not to consider the elevator as being a kind of load that was detrimental in its present state, because it is running all day long. But that does not alter the fact that if it does run all day long it only has a load factor of five per cent., and the revenue of that per kilowatt is only $181 per year, even at 30 cents per kilowatt hour, and that it will come on and be on the top of the peak of your maximum load. As an instance of that, I have a practical figure of an elevator which does require about 30 kilowatts to start it up, and its bill is $75 per month, and it does come on the top of the peaks at the maximum load.

(To be continued.)

No Standing in Court.

Trade Combinations are Dangerous to the Peace and Good Order of Society.

Judge Baker's Decision in the Harrow Trust Case.

The following is an abstract of Judge Baker's recent decision at Indianapolis, refusing an injunction against an acknowledged infringer of patents owned by the Harrow Trust :

"So far as I can perceive, the complainant is organized to receive assignments of the legal title of harrow patents, to grant back licenses to assignors to use and enjoy the same, to collect from each member of the combination or trust $1 as a license fee for each harrow manufactured and sold, to regulate and control the price at which harrows may be sold by the members of the combination, and to prosecute and defend all suits involving the alleged infringement of such assigned patents.

"It seems to me that such a combination is illegal, and that its purposes are violative of sound public policy. The common law forbids the organization of such combinations composed of numerous corporations and firms. They are dangerous to the peace and good order of society and they arrogate to themselves the exercise of powers destructive of the right of free competition in the markets of the country, and by their aggregate power and influence imperil the free and pure administration of justice.

"Complainant says that its title to the patent in question is valid, and that it has a lawful right to its protection from invasion by a stranger, regardless of the objects and purposes of the combination which it represents. On the other hand, the defendants contend that to give its title protection would be to give aid to the unlawful purposes of the combination. In suits at law it is doubtless true, as a general proposition, that a wrongdoer will not be permitted to dispute the legal title of one in possession of money or property by showing that the title thereto was unlawfully acquired, or that the owner intends to apply it to an unlawful use. I have strong doubts whether this rule ought to apply to a suit in equity, where nothing but clean hands and a good conscience will move the court to act. The combination represented by the complainant is not illegal in any other sense except that the law will not lend its aid to the accomplishment of its purposes. The common law does not prohibit the making of such combinations. It merely declines after they have been made to recognize their validity by refusing to make any decree or order which will in any way give aid to the purposes of such combinations. It seems to me that the court connot sustain the present bill without giving aid to the unlawful combination or trust represented by the complainant. The question is not free from doubt; but in case of doubt I feel it my duty to resolve it in such a way as will not lend the countenance of the court to the creation of combinations, trusts or monopolies. They have already grown to alarming proportions, and courts, to the full extent of their powers, ought to discountenance and repress them."

What the Public has Waited for.

A Formidable Rival to the Bell Telephone Company.

Money, Men and Methods are All Right.

The Standard Telephone Company, of 68 Broad street, New York, announces that it is ready for business throughout the United States. The capital of the concern is $10,000,000. Its board of directors is made up of Thurlow Weed Barnes, president; John A. Brill, president of the J. G. Brill Company, car builders, of Philadelphia, Pa.; Carl F. Baker, of the hardware, steel and iron house of H. Baker & Co., of New York; John W. Candler, formerly Representative, railroad president and merchant, of Boston, Mass.; George Crocker, of San Francisco, Cal.; Henry Merz, president of the Heller-Merz Company, manufacturers of colors, of New York; Allen T. Nye, promoter of the company; Manning C. Palmer, president of the Syracuse National Bank and Electric Light Company, of Syracuse, N. Y.; Felix Rakeman, of Bulch & Rakeman, of Boston; John E. Searles, secretary and treasurer of the American Sugar Refining Company, better known as the Sugar Trust, of New York; Charles T. Strauss, of Charles T. Strauss & Brothers, importers of lace, of New York, and Louis Windmuller, of Windmuller & Roelker, of New York.

The company proposes to make a rate of $25 per subscriber in New York City. Local companies with State rights have already been organized in New York, Boston, Philadelphia, Jersey City, Washington, Cleveland, Indianapolis, Detroit and many other cities.

It is said the plan of operations will be similar to that of the Bell people. A large number of politicians in various localities have been interested.

It looks as though the enterprise was the first one in the field with all the facilities for conducting a successful business in opposition to the Bell Company.

It will have the public in its favor from the start, and not alone because it offers cheaper service, but because of the rascally methods of the Bell people in the Patent Office, where they committed what has been judicially characterized as "grand larceny from the people of the United States."

Receiver for the Mather Co.

The Reorganization Not Successful.

On Saturday last, Mr. Charles M. Jarvis, of the Berlin Iron Bridge Company, and one of the directors of the Mather Electric Company, was appointed receiver of the latter company.

About two years ago the Mather Company compromised with its creditors, paying, we believe, about 40 cents on the dollar.

Although the leading stockholders are men of large wealth, the company has not had anything like enough capital to work on. It seems to have been the intention of those in control to use long credits in place of working capital until such time as it was certain that a further investment would pay.

The creditors of the company are entitled to every dollar of their claims, and we presume they will be paid in full. Indeed it is not apparent how the concern could go on again on any other plan.

Truth Expressed in Poetic Language.

"ELECTRICITY is a beneficent fairy who, with infinite tenderness, now offers to open the unexplored portions of her domain, and to yield up her treasures to you.—*Alfred Picard.*

THE ELECTROPOISE AND ITS PROMOTERS.

Where Does the Responsibility Rest for the Continuance of the Swindle ?

On March 14 it was reported from Chicago that Dr. W. C. Gray, editor of the *Interior*, was in trouble with his constituents because his paper, the organ of the Presbyterian Church in the West, had appeared with the partially nude picture of a prominent burlesque actress covering almost the entire first page.

Of course this was due to a mistake, which the Doctor explained satisfactorily.

But we do not know why the readers of the *Interior* should have been surprised. After so-called religious journals like this one, or the *Observer*, the *Evangelist*, the *Christian Standard*, the *Churchman* and dozens of others have violated all the laws of decency and propriety, have thrown aside the obligations which they are supposed to bear to the public, by persistently printing the advertisement of a notorious swindle such as the Electropoise, we see no reason for surprise if they go one step further down the scale of journalism and print nude pictures or nasty stories.

The publishers and editors of these papers have shown as clearly as they could that all they look for is revenue, whether obtained from legitimate sources or from the advertisements of swindlers.

They would doubtless change the character of their papers completely into anything that would pay better if they knew just what was a sure venture. Conscience does not guide them.

They cannot plead ignorance. ELECTRICITY, in its complete exposé of the fraudulent device and of the methods of its promoters, left them no ground for this excuse. Indeed, if they had the least anxiety to know the truth they could have informed themselves, as we did, by investigation and by referring the matter to authorities competent to judge of the quality of the Electropoise.

Not one medical man of standing, not one single scientist can be found to endorse it. ELECTRICITY referred it to six of the leading electrical scientists of the country and to a dozen of the leading physicians in New York City, every one of whom pronounced it an unqualified fraud.

The policy adopted by the larger number of the religious papers shows them to be conducted on infinitely lower lines than the leading daily papers of the country, or than the trade papers. It shows that the standards of morality of the organs of the church are lower than those prevailing in ordinary commercial circles, lower than those governing the conduct of gentlemen anywhere. These papers would accept pay for any advertisement, however gross the fraud intended, if that fraud were disguised so that they could escape the law governing such matters. They would print lottery advertisements if they dared.

If the publishers of the New York *Evangelist* and the New York *Observer* have any confidence in their own position in this matter let them avail themselves of the following offer :

ELECTRICITY will divide $1,000 between any two charities named by those two journals if they will secure the admission of the Electropoise advertisement into the columns of the *Youth's Companion*, for instance, or any one of a dozen other papers which we can name.

If the Electropoise is not a swindle, it will be easy for these gentlemen, assisted by the Rev. Dr. De Puy, to convince any fair-minded publisher that the advertisement should be accepted.

As to the *Churchman*, it is largely removed from criticism by the statement made by a member of its staff to a representative of ELECTRICITY, that they did not consider it their duty to exclude *any advertisement* of any concern which could pay its bills; they did not consider themselves bound to discriminate between legitimate businesses and frauds. True, he said, if anyone advertised for a governess, or something of that nature, by which young girls might be lured to their ruin, they would investigate the matter and refuse the advertisement. This is the only species of advertisement mentioned on which the *Churchman* would draw the line.

If the *Churchman* would now go one step farther and print its views on this subject every week at the top of its first advertising column, there would be no ground for criticism remaining.

ELECTRICITY again congratulates three of its religious contemporaries which have shown that they prefer sending clean and unobjectionable advertisements to their constituents over the few paltry dollars which they could make by advertising the fraud called Electropoise—

The Christian Advocate, New York,

The Sunday School Times, Philadelphia,

which would not accept the advertisement at all, and

The Outlook, New York,

which dropped it after ELECTRICITY's exposé appeared.

If any others desire to be added to this roll of honor, let them send in their names with the facts showing that they are entitled to the mention.

We print herewith a few of the hundreds of letters received by us on this subject. Some of them are amusing, and some ought to make one or two publishers stop to think :

To the Editor of ELECTRICITY.

I saw the Electropoise advertised in *Zion's Herald*, Boston, and a minister's name given as agent. A. G.

Norwood, Mass.

Either Deceptive or a Fraud.

To the Editor of ELECTRICITY.

Have received your paper, ELECTRICITY, and had previously received some extracts from your paper in the form of criticism upon Electropoise. I am in possession of one, bought in consequence of the testimonial of the publisher of the *Christian Standard*, Boston. I put it aside some time ago, convinced that either there was some defect in the instrument or it was a fraud.

Is the instrument described in the enclosed pamphlet of the same character ? Yours truly,

E. S. S., Methodist Minister.

Sandhurst, Ontario, Canada.

This Man Was in Hard Luck.

To the Editor of ELECTRICITY.

Gentlemen, in reply to your article entitled Electropoise I desire to say I have been afflicted with neuralgic rhumatism for 30 years—piles for 20 years—constipation 12 years—Kidney trouble 5 or 6 years. I have tried everything heard of and spent much money for relief: about one year ago bought an Electropoise—or "Oxydonor Victory." The results to-day are—entirely cured of constipation: entirely cured of Kidney trouble, partially cured at least greatly relieved of Piles—and much benefit received as to rhumatism—Entirely cured allso of Variocele and greatly benefited in general health which had become run down. Nothing else was used after receiving the ——.

Will you please explain how I was *humbugged* I am not interested in this apparatus one cent other than as stated above. Mr. Craig of the Shipbuilding Co. of Toledo might give you a similar recommendation.

My dear sirs, Electricity is a mystery yet and we don't understand all about it. There is much to learn yet. So is magnatism—which is but negitive electricity. I have studied this silent force just enough to know that we know nothing as yet. Very truly yours,

O. A. BUSARD.

Marion, O.

These Clergymen Were Humbugged—Perhaps.

To the Editor of ELECTRICITY.

Permit me to express my appreciation of the crusade against quacks and quackeries which you are so earnestly waging. Particularly do I rejoice over your exposure of that diabolical swindle, the "Electropoise." At least two years ago I took to task the publishers of the *Christian Witness* of Boston, expressing in a personal letter my astonishment at the fact that they would advertise such a humbug. I received in reply a letter stating that the publishers themselves—Revs. McDonald and Gill—had both been tremendously blessed by the use of the Electropoise. That cured me of the *Christian Witness*.

Then came the endorsement of Dr. De Puy, assistant editor of the *Christian Advocate*. As a regular subscriber of that paper I took this as a personal insult. Yours truly,

WM. L. CLARKE.

The Edison Electric Illuminating Company of New York.

Is This True?

To the Editor of ELECTRICITY.

Find enclosed two Electropoises opened at my own instance February 1, 1895, by J. B. O'Mera, chief engineer and electrician of the Union Club, 21st street and Fifth avenue. The *Evangelist* quite recently refused Electropoise advertisements, but after personal interview with Du Bois they sold themselves outright through large contract for advertisements, representing a very big sum of money, at *Evangelist's* own rate. This can be verified. Yours, etc.,

New York. H. K. LONG.

ELECTRICITY, the leading journal in this country devoted to that science, says that the Electropoise is a rank fraud. The editor bought an instrument and examined it and states that the claims of the owners that it possesses any virtue as a remedial agent are absolutely talse. He also puts the cost of manufacturing the Electropoise at 42 cents. It is sold at $25. The editor makes an earnest appeal to all respectable publishers to discontinue advertising the Electropoise.—*The Great South.*

A Dangerous Competitor.

Our fighting contemporary, ELECTRICITY, like the pitcher that went to the well too often, has come to grief.

Some weeks ago it began a crusade against a notorious fake cure-all, called the Electropoise. This Electropoise is a fraud that has a great run among weak-minded and credulous persons and in the columns of the religious press. It will cure anybody except a sick hen, and the only reason that the hen is proof against its wiles is that the hen is deficient in imagination.

Our contemporary pursued its devastating career unchecked, to the great discomfort of the church papers, until a man in Philadelphia came to the rescue, and in a letter of great originality in spelling, punctuation and the use of capital letters, showed the secret animus that inspired Editor Greene. He pointed out that the Electropoise was a competitor of Mr. Greene's ELECTRICITY and was making great inroads on his business.

Mr. Coleman, who thus exposes the secret designs of our contemporary, is evidently a man of careful and impartial judgment, for he writes : "I kan't say there ain't no Merit In your Electricity that would be wrong for me to do." Still he is evidently of the opinion that our contemporary could not cure a broken leg or put a man to sleep as quick as the Electropoise.

The Philadelphia man writes : "I was a compleat wreck my self from Blood Poison and I cured myself" with the Electropoise. After reading his letter one may possibly doubt whether the cure was so "compleat" as he thinks. Still Editor Greene has apparently not had much better luck in his attempt to cure a case of "Blood Poison" in a certain well-known corporation. He has come nearer killing than curing. As a business competitor of Electropoise ELECTRICITY is not a success.—*Pacific Electrician.*

He Believes In It.

To the Editor of ELECTRICITY.

I notice an "Electro Medical Fraud," an article from *Western Christian Advocate.* Why don't your great men that publish your paper the ELECTRICITY tell us what the alleged closed cylinder of two rare metals are composed of. It only shows your great electrical chemists are not so smart as your Book wants to make people believe they are. Keep on (Greene) perhaps people won't think you are so (green) after all when you display your smartness concerning the Electropoise these very smart people whom write you with very big words with no meaning or no sound logic to explain what they are talking about. sometimes Cultured minds like you selves are like stubborned asses that kick in the Harness not knowing what they are kicking about. So you go along groping in the darkness expecting some fool like your self may give you some day some light to help you along your poor Book Electricity. What poor Mortals we be. But poor (Greene) take courage poor (Greene) you will get to your haven of rest after while. Keep on publishing your rubbish concerning the Electropoise and your poor Book will place you with the great books of the world Great Head you have. Yours Respt,

New York. Electropoise.

A New Wiring Slide Rule.

We are indebted to Prof. E. P. Roberts, of the Correspondence School of Technology, Cleveland, O., for a very neat and simple little wiring calculator, which is destined, we think, to come into wide popularity among those who have to do with electric light wiring. The calculator is neatly made of celluloid, with metal trimmings, and comes in a flat leather case of convenient size for the vest pocket. The scale is based on the law of the B. & S. G., and ranges from No. 20 up to 500,000 circular mils. The directions for its use are so simple as to be readily understood, and by simply moving the slide until the pointer is in the proper position the results may be read off direct.

In every wiring problem there are three elements involved, viz., ampere feet (or lamp feet), volts loss and size of wire. If any two of these are given, the third is determined at once. For the purpose of avoiding calculation, resort is usually had to wiring tables or curves, but the slide rule is more convenient than either of these and quite as accurate.

We understand that Prof. Roberts first introduced this rule to facilitate the work of his students, but that its immediate popularity was such as to induce him to bring it into wider use by putting it on the market. It is being sold at 50 cents, at which price it may be had, postage prepaid, either of Prof. Roberts himself or of Electricity, 6 Park Place, New York.

General News.

What is Going on in the Electrical World.

Arcadia, Wis.—A stock company is to be formed here to put in an electric light and water supply system.

Waverly, N. Y.—South Waverly was to decide at an election held on the 9th, whether the village should have electric lights.

Elizabeth, N. J.—The fire committee of the city council have reported in favor of getting an electrical fire alarm apparatus for the city.

Oakland, Md.– The receivers have sold the plant of the Oakland Electric Light and Power Company at public auction to D. E. Offutt for $5,000.

Oswego, N. Y.—The directors of the Oswego Street Railway Company have decided to apply to the courts for the appointment of a receiver for the road.

Martinsburg, W. Va.—The electric light plant of this city has been sold at public auction by the creditors of the concern to W. E. Tebo for $18,500.

Chelsea, Mich.—The council, in accordance with the vote of the people at the recent election, will make a contract with the Chelsea Electric Company for lighting the village.

Ocean City, Md.—The Sinepuxent Beach Company intends making extensive improvements at this resort; an electric plant will be provided for lighting the hotels and cottages.

Brunswick, Ga.—Captain W. A. Jeter has applied to the city council for a five years' franchise to build and operate an electric car line in this city. The franchise will probably be granted.

Elberton, Ga.—At the recent election to decide the question of bonding this town for the purchase and instalment of an electric light plant, the vote in the affirmative was almost unanimous.

Troy, N. Y.—The directors and stockholders of the Cohoes City Electric Railway Company have voted to issue $50,000 worth of bonds, the money to be applied to the construction of the road.

White Plains, N. Y.—Under the terms of the charter which recently went into effect the trustees are commanded to advertise for proposals to light the streets of the village for three years from November next.

Lafayette, Ind.—The Citizens' Gas and Electric Power Company, with a capital stock of $100,000, has been organized here to compete with the present electric lighting company, a Thomson-Houston concern.

Ocean Grove, N. J.—It is reported here that plans for an electric railway system in this place are under consideration and are likely to be carried into effect so as to have the road in operation early in the summer.

Poughkeepsie, N. Y.—The Poughkeepsie Electric Railroad Company is trying to purchase the Poughkeepsie and Eastern Railroad for the purpose of equipping it with electricity and extending the track to Millbrook.

Fort Dodge, Iowa.—The Fort Dodge Electric Company has completed the rebuilding of its electric light plant and added machinery to furnish power for operating the trolley railway for which it recently got a franchise.

Port Huron, Mich.—Suits have been commenced against the Excelsior Electric Light Company of Port Huron to recover an aggregate of over $40,000 due on notes against that company to local banks and individuals.

Williamstown, Mass.—The preliminary survey for the electric railway between this town and North Adams has been made, and work on the line will begin immediately after the bill granting the right of way is passed by the Legislature.

Vicksburg, Miss.—Proposals will be received by the mayor, W. L. Trowbridge, until April 15, for the lighting of the city of Vicksburg with 81 electric arc lights of 2,000 c. p. and 84 incandescent lights of 50 c. p. for periods of three or five years.

Oneida, N. Y.—Last week parties were here consulting about an electric railroad. Their scheme is to purchase the street railway and extend it up through Oneida Castle. A line from here to Oneida Lake by way of Canastota is also talked of.

Greenbush, N. Y.—The highway commissioner of East Greenbush has granted a franchise to F. R. Barnes to construct and operate an electric railway through that town from Albany to Castleton. Mr. Barnes is backed by Boston capitalists.

Knoxville, Tenn.—A representative of the Excelsior Electric Light Company of New York has held conferences with the mayor and city engineer on the subject of a city lighting plant. He stated that a plant of sufficient capacity could be erected here for $40,000.

Attleboro, Mass.—The Interstate Street Railway has been sold by public auction for $101,000 to E. R. Price for the trustees of the syndicate which bought the Attleboro, North Attleboro and Wrentham road. The sum of $15,000 was deposited as a forfeit.

Stroudsburg, Pa.—Judge Craig has issued a decree ordering a receiver's sale on April 22 of the personal property and effects of the Delaware Valley Electric Railway Company. The sale will include the property and franchise of the East Stroudsburg and Matamoros Railroad Company.

New Brighton, S. I.—The Staten Island Electric Railroad Company (Thomas syndicate), which obtained a franchise from New Brighton, has deposited $10,000 with the Central Trust Company as a guarantee for the construction and operation of the line in accordance with the terms of the franchise.

Jacksonville, Fla.—The Jacksonville Electric Light Company, having failed in its attempt to have the city enjoined from serving the citizens with light from the new municipal plant, intends to compete with the city in furnishing light to private consumers at the same prices as the city advertises.

Jersey City, N. J.—The power-house of the New Jersey Electric Railway Company, now in course of construction on the Meadows, will be completed and fully equipped with its engines and dynamos by May 1. The power-house is 75 by 175 feet in size and of brick. The car storage house will accommodate 65 cars.

Richmond, Va.—A conduit ordinance is before the city council requiring telegraph, telephone and electric light and power wires and cables, including feed but excluding trolley wires, and all other appliances for conducting electricity, and the poles therefor, to be removed from certain named streets.

Woburn, Mass.—Judge Knowlton, of the Supreme Court, has ordered the plant of the Woburn Electric Light Company to be sold on May 15, subject to the first mortgage of $35,000 and all incumbrances and liens except the second mortgage for $100,000 and the receiver's certificates, amounting to $1,000 more.

Asbury Park, N. J.—The plant, franchise and good will of the Neptune Electric Light and Power Company of this city have been sold for $61,000, subject to a mortgage of $41,000. The purchaser was George A. Smock, on behalf of the recently organized Asbury Park Electric Light Company. The original cost of the plant was $160,000.

Norfolk, Va.—The syndicate who have been negotiating for the purchase of the street railroad have made a deposit and are expected to take charge immediately. The old tracks will be taken up and a complete electric system put in. The purchasers will expend $150,000 in improvements and extensions including West Norfolk and other suburbs.

Sharon, Pa.—A complete reorganization of the Shenango Valley Electric Company has been effected. The officials elected were: President, A. M. Jolly, Beaver Falls; secretary, A. R. Leyda, Beaver Falls; treasurer, A. F. Barker, New Brighton. Directors: J. A. Whitla, A. R. Leyda, J. P. Stone, A. W. Jolly, Beaver Falls, and F. G. Barker, New Brighton.

Savannah, Ga.—Judge Speer has issued an order directing the receivers of the electric street railway to proceed with the reorganization of the company's property. For the old bonds there will be exchanged $600,000 new bonds at 5 per cent., which take up $800,000 now outstanding. The debts of the company will be paid out of the Brush Electric Light Company's stock now in the company's treasury.

Passaic, N. J.—The gas and electric companies have consolidated under the title of the Passaic Lighting Company. The new directors are W. R. Brown, E. LeB. Gardiner, Richard Morrell, H. P. Brown, B. W. Spencer, G. A. Hobart, J. J. Slater, L. B. Gawtry and John A. Willett. The officers are W. R. Brown, president; B. W. Spencer, vice-president and treasurer; E. LeB. Gardiner, secretary.

Memphis, Tenn.—The Memphis Street Railway Company, F. G. Jones, Thomas B. Turley, Luke E. Wright, John K. Speed and W. B. Mallory, incorporators, has filed its charter of incorporation in the register's office. The charter authorizes the consolidation of all the present electric roads operated in and around Memphis under one name.

Baltimore.—A new four-masted schooner, the C. S. Glidden, just arrived here with a cargo of phosphates, is believed to be the only electrically equipped schooner on the coast. The commander of the schooner can sit in his cabin and summon the steward, or give orders about handling the sails by means of electric buttons. Is the quarter deck doomed?

Eau Claire, Wis.—The new Electric Light and Power Company will expend nearly $300,000 in improvements here. The upper dam will be improved so as to give a fall of 16 feet, the lower dam will also be improved and the horse-power greatly increased. A large dam will also be constructed at the falls near Altoona, all of which will give the new company a capacity of 600 or 700 horse-power.

Niagara Falls, N. Y.—The first test of the 5,000 h. p. dynamo recently set up in the power-house of the Niagara Falls Power Company was made on the night of the 5th inst., and was followed next day by another test in the presence of the officers of the Cataract Construction Company and a number of other gentlemen, including several English capitalists. Both tests were pronounced thoroughly satisfactory.

La Porte, Ind.—A franchise has been granted for an electric road between La Porte and Michigan City, a distance of 12 miles. This is said to be the inception of a scheme, backed by Eastern capitalists, to build an electric railway to Indianapolis and, paralleling the Lake Erie and Western Railroad, to the State capital, which is estimated to cost over $1,000,000. The Michigan City and La Porte road is to be an experimental line to determine the feasibility of the project.

Flushing, N. Y.—The Flushing and College Point Electric Street Railway has been sold by the special master to Cravath & Houston, representing the reorganized company for $25,000. The road will be operated by the new company, which promises improved service. Among those forming the reorganized company are Daniel Odem, E. Bayard Halstead, Paul D. Cravath, John W. Houston, V. K. McElhenny, Frank A. Dillingham, Philip F. Kobbe, Harvey Romer and Charles Snow Kellogg, of New York.

Cleveland, O.—The Cleveland, Painesville and Eastern Railroad Company has filed an application in the county commissioner's office for a 25-year franchise for a line to run from the Euclid Creek terminus of the Big Consolidated line out Euclid avenue to the county line. The line is to be operated by electricity, and is backed by Henry A. Everett, the president of the Consolidated Company.

Atlanta, Ga.—The Georgia Electric Light Company has petitioned the council for a renewal of its lighting contract with the city for a period of five or ten years, at a reduction of 10 and 15 per cent. respectively, and pleads for preference on the ground that it has invested $750,000 in the business, has furnished satisfactory light and has never earned or paid a dividend. The present contract expires July 1.

Chester, Pa.—The directors of the proposed Media, Middletown, Aston and Chester Electric Railway Company have voted to increase the capital stock of the road from $30,000 to $150,000. It is expected that the contract for the construction of a portion of the road will be given out in a few weeks. Samuel L. Kent, of Clifton Heights has been elected a director to fill the vacancy caused by the death of Hon. William Ward.

Buffalo, N. Y.—It is understood that at a secret session of the committee on the 2d the corporation counsel was instructed to draw up a franchise for supplying power to Buffalo, which is to be submitted to the Niagara Falls Power Company at an early day. The grant is for fifty years. The Power Company will probably arrange to use the New York Central's road for an overhead wire line for the transmission of electrical energy to this city.

Calais, Me.—The People's Electric Light and Power Company, with a capital stock of $50,000, has been organized in Calais, and two per cent. of the stock has already been paid in. The intention of the company is to provide power, light and heat to Calais patrons. Hon. John G. Murchie is president.—Gerald & Libby have sold their interest in the Calais Street Railway to the Messrs. Curran and Charles Pray, who will have the management of the plant.

Chicago.—The *Journal* states that "the largest system of electric street railway in the world under the management of an individual owner is that which will soon be put into operation on the West Side by Charles T. Yerkes. The entire system is composed of about 200 miles of road, and it cuts up that portion of the city into sections, penetrates districts which have not heretofore had locomotive privileges, and presents the most extensive plan of main and cross-town lines ever built."

West Salem, Wis.—S. D. McMillan has been granted a franchise to establish an electric light and power company in this village. Mr. McMillan controls the fine water power at Neshonoc, about a mile and a half from West Salem. It is well known that his purpose is to reach La Crosse with his power within a year. Another company is endeavoring to secure rights lower down La Crosse River solely for developing electricity to be conveyed to La Crosse. It is likely an electric railway line up La Crosse valley will be organized before the year is out.

Utica, N. Y.—A dispatch from Watertown to the *Press* states that "a big scheme is on foot to utilize the water power of the Black River for the generation of electricity. Owners of water rights in Watertown and neighboring towns that border on the Black River have been asked for options on their privileges. It is understood that the Rome, Watertown and Ogdensburg Railroad Company is the prime mover in the scheme and that electricity will be used as the power by which railroads will be operated in Northern New York."

Red Bank, N. J.—A party of New York, Brooklyn and Newark men have been looking over the route proposed for an electric railway between Red Bank and Long Branch, and subsequently decided to ask the board of commissioners for a franchise for the road in Red Bank. The road is to cost $300,000 and the indications are that it will be built at once. S. B. Dutcher and Benjamin Frick, of New York; S. S. Whitmore, P. B. Purdy, J. F. Dobson, D. S. Arnott and A. B. Eldridge, of Brooklyn; Robert Lightfoot, of Jersey City, and W. B. Williams, of Newark, are the men mentioned in connection with the project.

Lincoln, Neb.—The State Senate has passed a bill enabling cities of a population less than 5,000 to make contracts for lighting plants. It provides that these cities are authorized to make contracts with and authorize any person, company, or association to erect and maintain gas or electric light works, and give such person, company, or association the exclusive privilege of furnishing gas or electric lights to light the streets, lanes, and alleys of such cities for any length of time, not exceeding twenty-one years, and to levy a tax not exceeding five mills on the dollar in any one year, for the purpose of paying the costs of lighting the streets, lanes and alleys of said cities.

Albany, N. Y.—The Governor has signed the bill authorizing North Tonawanda to establish an electric lighting system and the bill authorizing Lockport to vote on the question of establishing an electric light plant at a cost not to exceed $25,000.—The Assembly has passed these bills: Mr. Ainsworth's, increasing the amount for which villages may contract with electric light companies; the bill requiring all motormen and electrical assistants in New York, Brooklyn and Buffalo to pass an examination by a board of electrical inspectors, who shall be appointed by the mayor.—A bill has been introduced in the Assembly empowering the Equity Gas Light Company to supply electricity in Brooklyn.

Stamford, Conn.—The Stamford street railway has been purchased by a syndicate of New York capitalists, among whom are J. Pierpont Morgan, E. C. Benedict and H. O. Havemeyer. The sale, it is understood, was completed the last week in March, ending negotiations first entered into a year ago. The plans of the buyers are as yet unknown, but it is rumored that the road will be equipped with electricity throughout; that a power plant will be erected at Glen Brook, and that power will also be supplied to the New Canaan and Stamford branch of the Consolidated. The deal is reported to be a move on the part of officers of the Consolidated road to control by investments by its large shareholders the systems of trolley lines which may run parallel to its tracks.

Los Angeles, Cal.—The Los Angeles Consolidated Electric Company has passed out of existence, giving place to the Los Angeles Railway Company, which was organized for the purpose of taking over the franchises and all the property of the Consolidated Electric Company. The men at the head of the new company are well known in business circles in San Francisco, among them being A. H. Payson, the capitalist, and George Stone, president of the People's Savings Bank. Morris Trumbull, of Chicago, was appointed temporary general manager. Mr. Trumbull says "it is intended that the service shall be improved in many ways, and at once. It is realized that a large number of cars are needed in order that a better time schedule shall be observed. The cable lines are to be electrized, and already orders have been placed for material looking to a speedy change in this direction."

Burlington, N. J.—Contracts have been awarded by the Pennsylvania Railroad Company for the electrical equipment of the Burlington branch of the Amboy division, which connects Mt. Holly and Burlington. The Westinghouse Company will furnish the engine and generators, and the combination cars, for baggage and passengers, will be equipped with Westinghouse motors and car equipments. There will be three of these cars, two of them provided with two motors of 75 horse-power each, making 150 horse-power to a car, and these motors are to drive the cars at a rate of 45 to 60 miles an hour. The third car will have four motors of 50 horse-power each, a total of 200 horse-power. Railway motors of 75 horse-power have never been used, and those for use on these cars are to be built especially for them. The use of four motors on a car is also an experiment. These cars are intended to draw one, two or three Pennsylvania Railroad coaches such as are used in the regular traffic.

Telephone and Telegraph.

A telephone exchange is being put in at Waycross, Ga.

The Phœnix Mutual Telephone Company, organized under the laws of New Jersey, has filed articles of incorporation in Jersey City. The capital stock is $20,000. Incorporators: Thomas Brady and Chester D. Ayers, of Bayonne, and George Christian, of New York.

Messrs. Clarence F. Hotchkiss, George C. Bayless, Edward L. Rose, Cyrus Strong, Jr., Judge Downs and Col. Dunn are back of the movement for a new telephone company in Binghamton, N. Y.

A movement was started at Garrison, Col, last week for the building of a telephone line between there and the Duncan mining camp with the result that in less than three hours enough money had been raised to pay almost the entire cost of the line.

Pittsburg, Pa., business men are making a move for lower telephone rates, and promise encouragement to any new company that will give them good service at reasonable rates. A Chamber of Commerce man says that "Pittsburg pays higher prices for telephone service than any other city in the world."

The National Telephone Construction Company has petitioned the village board of Waukesha, Wis., for a franchise to construct and operate an exchange in Waukesha.

When the uncertainty in regard to underground wiring is removed, St. Louis will be placed in line with the other great cities of the Union by the erection of a long distance telephone system, which has been delayed by the council's dilatory action in the matter of subways.

At a recent meeting of the stockholders of the West Shore Telephone Company at Kingston, N. Y., it was agreed to have the charter amended so as to permit an extension to Stamford, thus covering the Ulster and Delaware territory where subscriptions for stock have already been made, and also to permit an extension to Walden from Gardiner.

Subscribers of the Hudson River Company in Kingston, N. Y., have been informed that the former rate of $5 per month is cut to $25 a year. This was done to compete with the West Shore Telephone Company, which recently put up a line along the Hudson Valley and cut the old rate down to $30 a year.

The board of directors of the Home Telephone Company of Mobile, Ala., have elected the following officers: H. Piser, president; James K. Glennon, vice-president; W. H. Fitzpatrick, secretary; Adam Glass, treasurer. This completes the organization of the company and preliminary work on the plant has already begun. Nearly 500 subscribers have been secured and new names are being added to the list daily.

The Indiana Telephone and Construction Company have asked the city council of Muncie, Ind., for a franchise to put in a telephone system in that city.

The county board of Waterloo, Ill., has granted Drs. S. C. and S. S. Skeel and John A. Jakle the right to erect a telephone line from Harrisonville to Waterloo. Work on the line will begin at once.

At Shamokin, Pa., a local telephone company, to be known as the Anthracite Telephone and Supply Company, has been formed by Shamokin and Mt. Carmel capitalists.

The Harrison Telephone Company has organized a branch at Sioux City, Iowa, and will begin putting in the new system in a few weeks.

The Harrison Telephone Company is making an effort at Olean, N. Y., to get 150 subscribers at $30 for offices and $18 for residences per year. The established concern there, the Western New York and Pennsylvania Telephone and Telegraph Company, has reduced its rates.

The Anderson (S. C.) Telephone Company is putting in 'phones, doing inside wiring and completing such details as are necessary to a perfect telephone system. The company has fifty-two subscribers.

The Home Telephone Company of Wabash, organized for the purpose of furnishing telephone service to the city of Wabash, Ind., has been incorporated by residents of that city. The capital stock is $10,000.

The Menominee Range Telephone and Construction Company has been organized by local capitalists at Iron Mountain, Mich., and will operate an exchange in Iron Mountain, Norway and other range towns. It will furnish instruments for $24 a year.

At a meeting of citizens at Rockford, Ill., last week it was decided to organize the Rockford Telephone Company with a capital stock of $60,000, a large part of which was subscribed. Each subscriber for a 'phone is to take $100 worth of stock, payable in instalments. The rates fixed for the new company are $30 a year for business houses and $20 for residences. The citizens' committee, while recommending no system at present, have four under consideration for adoption. All of the leading citizens are in the fight for cheaper 'phone rates and the chances are the Bell monopoly will be driven out.

The Wizart Telephone Company's representative, C. J. Willow, has visited Omaha and Council Bluffs for the purpose of interesting telephone users in the Wizart Company's system.

The Central Pennsylvania Telephone and Supply Company has reduced its rates about 25 per cent. at all exchanges in its territory.

The local Phœnix Telephone Company of Greencastle, Ind., has been incorporated. Its capital stock is $8,000. The company was organized for the purpose of furnishing telephone service in Greencastle.

The Nebraska Telephone Company has had a representative in Tecumseh consulting with business men in regard to erecting a telephone system in that town. He met with much encouragement.

The Indianapolis Phœnix Company, organized for the purpose of operating a telephone system in Marion County and Indianapolis, has been incorporated. Its capital stock is $200,000, and among the stockholders are Alfred B. Gates, Rufus K. Syfers, Charles A. McCleary, William N. Gates, George W. Stout, Charles F. Smith, George C. Webster, Edward M. Churchman, R. H. McCrea and Benjamin L. Webb.

The Mutual Automatic Telephone Company, a branch of the Automatic Telephone and Electric Company of New York State, has issued a circular in which it is intimated that the company will open offices in New York and Brooklyn as soon as arrangements can be made. The Strowger automatic telephone will be used and the projectors state that telephone rates will be radically lowered once the new system is in working order. Officers: Smith M. Weed, chairman of the board; J. Wesley Allison, president; Silas B. Dutcher, first vice-president; John C. McGuire, second vice-president; Henry N. Whitney, treasurer; A. B. Macklin, secretary. Executive Committee: Smith M. Weed, John C. McGuire, Silas B. Dutcher, J. Wesley Allison, David A. Boody. Board of Directors: Dr. W. Seward Webb, president Wagner Palace Car Company, New York; David A. Boody, banker and ex-mayor of Brooklyn, New York, vice-president Sprague National Bank; J. Wesley Allison, president Automatic Telephone and Electric Company; Henry N. Whitney, president Schermerhorn Bank, also of Kissam & Whitney, bankers, Wall st., New York; Silas B. Dutcher, president Hamilton Trust Company, Brooklyn, N. Y.; John C. McGuire, lawyer, surveyor of the port of New York; Joseph T. Keiley, lawyer, New York; A. B. Macklin, secretary Mutual Automatic Telephone Company, New York; John Jacob Astor, New York; Smith M. Weed, president C. O. and I. Company, German-American Investment Company, etc., New York; Charles F. Cox, president American Safety Deposit Company, vice-president Canada Southern Railway, vice-president Second Avenue Railway, New York.

COMMERCIAL PARAGRAPHS.

The Royal Electric Company of Peoria, Ill., have completed arrangements with Messrs. H. B. Coho & Company, No. 203 Broadway, New York, to handle their alternating current apparatus in the East. Messrs. Coho & Company have secured the services of Mr. George C. Hoffman, formerly of the Westinghouse Company, who will have charge of the alternating current department.

The Mather Electric Company of Manchester, Conn., have just closed a contract with the Berlin Iron Bridge Company of East Berlin, Conn., for equipping their new orge shop with electric power. A 40 K. W. generator and a 50 H. P. motor will be used.

MOONLIGHT SCHEDULE FOR THE UNITED STATES.

INCORPORATIONS.

The Topeka Water and Electric Power Company, Topeka, Kan.—to develop and improve water power from Kansas River and other places; construct dams, electric works, water works, compressed air, milling establishments, etc. Capital stock, $1,000,000. Promoters: F. A. Session, Ionia, Mich.; L. H. Withey, Anton C. Hoclenpyl, T. F. McCarry, Grand Rapids, Mich.

The Saranac Lake Electric Light Company, Saranac Lake, N. Y.—to use electricity for light, heat and power. Capital stock, $30,000. Promoters: Orlando Blood, Wallace Murray, O. S. Morse, all of Saranac Lake.

The Prospect Street Railway Company, Chester, Pa.—to build a street railway operated by electricity or other power than locomotive. Capital stock, $50,000. Promoters: Geo. Rodgmen, Wm. D. Pullon, Jr., Edw. J. Nugent, all of Chester.

The Chase Electric Cyclorama Company, Chicago, Ill.—to manufacture, buy, sell and operate electrical, photographic and optical machines, instruments and apparatus, stereopticon slides, lime light and all other lighting apparatus. Capital stock, $100,000. Promoters: Chas. A. Chase, D. Wiley McCaughey, Geo. E. West.

The Kansas Telephone and Electrical Company, Parsons, Kan.—to maintain and operate a system of telephones and electrical alarms and calls. Capital stock, $40,000. Promoters: A. B. Kerlin, Freeport, Ill.; D. S. Stewart, Shelbina, Mo.; C. W. Ryan, Parsons.

The Telegraphic Page Printing Company (incorporated in W. Virginia), New York, N. Y.—to manufacture, operate and sell electric printing telegraph machines and all other electrical and mechanical devices, etc. Capital stock, $500,000. Promoters: Edw. T. Hickey, Chas. H. H. Cottrell, New York City; Chas. F. Sesinger, Philadelphia, Pa.

The Steuben County Electric Telephone Company, Angola, Ind. Capital stock, $5,000. Promoters: Lorenzo Taylor, Sol. A. Wood, J. E. Naught, N. W. Gilbert, of Angola.

The Bristol Gas and Electric Company, Bristol, Va.—to operate a gas and electric light plant. Capital stock, $100,000. Promoters: J. H. Wood, H. C. Wood, R. W. Crenshaw, Bristol, Va.; Wm. Hurt, Lynchburg, Va.

The Berwyn and Deven Passenger Railway Company, Philadelphia, Pa.—to build a street railway in Chester County, Pa. Capital stock, $18,000. Promoters: Geo. Roney, John A. Carry, Russell Hawkins, Philadelphia.

The Newtown, Langhorne and Bristol Trolley Street Railway Company, Newtown, Pa.—to build an electric street railway. Capital stock, $60,000. Promoters: Geo. C. Worstall, Newtown, Pa.; Henry Lovett and Wm. B. Parry, Langhorne.

The Rawson Light and Power Company, Leicester, Mass.—to furnish light, heat and power. Capital stock, $25,000. Promoters: Edwin L. Watson, Walter C. Watson, Wm. F. Whittemore, J. S. Whittemore, Lory S. Watson.

The Bureau County Telephone and Telegraph Company, Walnut, Ill. Capital stock, $1,500. Incorporators: Joseph W. Ross, John H. Knight and A. E. Burres.

Richwood's Street Railway Company, Peoria, Ill.—to construct a street railway through the counties of Peoria, Tazewell and Woodford. Capital stock, $50,000. Incorporators: Robert M. Cox, James M. Morse, Theodore J. Miller.

The Cascade Light and Power Company, Cascade, Iowa—to furnish electricity for lighting, heating and power. Capital stock (paid up), $7,000, with the privilege to increase to $15,000. Incorporators: James A. Hayes, D. M. Finley, L. P. Freeman, H. L. Dehner, J. W. Beatty.

The Charleston Electric Company, Charleston, Ill. Capital stock, $5,000. Incorporators: Richard Cadle, Frank A. Brooks and W. A. Highland.

The Baird Electric Conduit Company, Chicago—to build and operate street railroads. Capital stock, $5,000,000. Incorporators: F. E. Baird, G. E. Baird, W. H. Craig.

ELECTRICAL PATENT RECORD.

LETTERS PATENT ISSUED APRIL 2, 1895.

ELECTRIC RAILROADS AND APPLIANCES.

536,704. Safeguard for Cable or Electric Cars. Geo. Rischmuller, San Francisco, Cal. Filed Feb. 24, 1894.

536,764. Electric Block-Signal. Fred P. Snow, Lynn, Mass. Filed April 27, 1894.

536,795. Switch for Street-Car Controllers. Gustaf Valley, Cleveland, Ohio, assignor to the Steel Motor Company, same place. Filed Dec. 3, 1894.

536,828. Supply System for Electric Railways. Albert C. Crehore, Ithaca, N. Y. Filed July 22, 1893.

536,855. System of Electrical Propulsion for Railway-Cars. Leon Dion, Natick, Mass. Filed June 14, 1894.

536,918. Closed-Conduit System for Electric Railways. Edwin D. Chaplin and Leon Dion, Natick, Mass. Filed June 14, 1894.

536,923. Safety Device for Electric Railways Having Sectional Conductors. Leon Dion, Natick, Mass. Filed June 14, 1894.

536,952. Conduit Electric Railway. Tyre C. Hughes and Arthur W. Adams, St. Louis, Mo., assignors of one-half to Ewing Hill and E. C. Smith, same place. Filed Feb. 12, 1894.

536,967. Trolley-Support for Electric-Railway Cars. Emil B. W. Reichel, Charlottenburg, assignor to Siemens & Halske, Berlin, Germany. Filed Oct. 25, 1894.

ELECTRIC LIGHTS AND APPLIANCES.

536,792. Socket for Incandescent Lamps. Francis H. Soden, Chicago, Ill., assignor to the Thomson-Houston Electric Company, of Connecticut. Filed Feb. 12, 1890.

536,856. Shade for Incandescent-Lamp Globes. Leon Dion, Natick, Mass. Filed June 14, 1894.

DYNAMO ELECTRIC MACHINERY.

536,608. Electrical Transformer. Malcolm Dickerson, Fort Wayne, Ind., assignor of one-half to John F. Curtice, same place. Filed Nov. 26, 1894.

536,748. Dynamo Driven from Axles of Railway-Cars. William Biddle, Brooklyn, N. Y. Filed May 31, 1894.

536,794. Electric Controller. Gustaf Valley, Cleveland, Ohio, assignor to the Steel Motor Company, same place. Filed Dec. 3, 1894.

536,816. Combined Dynamo-Electric Generator and Current-Director. James F. McElroy, Albany, N. Y., assignor to the Consolidated Car Heating Company, Wheeling, W. Va. Filed Jan. 2, 1892.

536,963. Dynamo-Electric Machine. James F. McElroy, Albany, N. Y. Filed July 24, 1894.

536,973. Brush-Holder for Dynamo-Electric Machines and Motors. Gustaf Valley, Cleveland, Ohio, assignor to the Steel Motor Company. Filed Dec. 15, 1894.

TELEPHONE AND TELEGRAPH APPARATUS.

536,655. Terminal Attachment for Flexible Conductors. Wilton L. Richards, Malden, assignor to the American Bell Telephone Company, Boston, Mass. Filed Sept. 10, 1894.

536,705. Telephoning Apparatus. William B. Robeson, Philadelphia, Pa. Filed Sept. 7, 1894.

536,763. Telephone. John Serdinko, San Antonio, Tex., assignor to the National Union Telephone Company, same place. Filed Dec. 4, 1894.

539,787. Telephone-Exchange System and Apparatus. Hammond V. Hayes and Theodore Spencer, Cambridge, assignors to the American Bell Telephone Company, Boston, Mass. Filed Sept. 10, 1894.

536,914. Telephone. Fred H. Brown, Chicago, Ill., assignor by mesne assignments, to the Economy Transmission Company, same place. Filed Oct. 17, 1894.

536,920. Telephone System. Frank R. Colvin, New York, N. Y. Filed Dec. 20, 1894.

BATTERIES.

536,689. Electric Battery. Hosea W. Libbey, Boston, Mass. Filed Feb. 23, 1894.

SIGNALS AND SIGNALING APPARATUS.

536,871. Electric Double-Semaphore Block-Signal. Nathaniel O. Goldsmith, Cincinnati, Ohio. Filed March 24, 1894.

536,872. Electric Block-Signal. Nathaniel O. Goldsmith, Cincinnati, Ohio. Filed March 24, 1894.

MISCELLANEOUS.

536,684. Self-Locking Cleat for Electric Wiring. Frank O. Creager, Marseilles, Ill. Filed Jan. 14, 1895.

536,730. Electrical Controlling System for Elevators. Cyprien O. Mailloux, New York, N. Y. Filed Dec. 20, 1894.

536,808. Contact-Finger for Electric Controllers. Samuel Harris, Cleveland, Ohio., assignor to the Steel Motor Company, same place. Filed Dec. 5, 1894.

536,809. Electrical Switchboard. Francis W. Jones, New York, N. Y. Filed Jan. 22, 1895.

536,811. Electric Mercurial Switch, or Contact-Maker. Hermann Lemp, Lynn, Mass., assignor to the Thomson-Houston Electric Company, of Connecticut. Filed July 26, 1888.

536,857. Means for the Insulation of Conductors of Electricity. Leon Dion, Natick, Mass. Filed Dec 6, 1894.

536,926. Electric Clock-Winding Mechanism. Martin V. B. Ethridge, Everett, and Joseph H. Eastman, Boston, Mass., assignors to the Century Clock Company, North Berwick, Me. Filed April 28, 1894.

536,974. Electric Organ-Coupling Mechanism. Edwin S. Votey, Detroit, Mich. Filed April 7, 1894.

536,975. Electrically-Controlled Magnet and Valve for Pipe-Organs. Edwin S. Votey and William D. Wood, Detroit, Mich. Filed April 7, 1894.

536,977. Electromagnet for Pipe-Organs. Edwin S. Votey, William B. Fleming and William D. Wood, Detroit, Mich. Filed April 7, 1894.

536,978. Electropneumatic Stop-Action for Pipe-Organs. Edwin S. Votey, William B. Fleming and William D. Wood, Detroit, Mich. Filed April 16, 1894.

DESIGN.

24,175. Telephone-Support. David J. Hauss, Cincinnati, Ohio. Filed Sept. 15, 1894. Term of patent 7 years.

ELECTRICITY.

VOL. VIII. NEW YORK, APRIL 17, 1895. No. 14

ELECTRICITY

Published every Wednesday by the

ELECTRICITY NEWSPAPER CO.

B. E. GREENE, PRES'T. L. J. MONTGOMERY, SEC'Y.

PUBLICATION OFFICE:

6 Park Place - New York

EDITORS: NELSON W. PERRY. BURTON E. GREENE. R. H. WILLOUGHBY.

BUSINESS MANAGER, - - JOHN L. GANS.

SUBSCRIPTION RATES:

UNITED STATES,	$2.50
IN CLUBS OF FIVE OR MORE,	$2.00
FOREIGN COUNTRIES,	$4.50
SINGLE COPIES,	10 CENTS

ADVERTISING RATES:

As ELECTRICITY reaches all classes interested in electrical work, its value as an advertising medium can be readily appreciated. Rates will be sent on application.

Changes for advertisements should reach the office not later than the Saturday preceding the date of publication.

ENTERED AT THE N. Y. POST OFFICE AS MAIL MATTER OF THE SECOND-CLASS.

EDITORIAL NOTES.

The Destiny of Gas. Our entertaining contemporary, the *Progressive Age*, the champion of the Welsbach light, in its issue for April 15 has a leader of a column and a half entitled "The Destiny of Electric Lighting," which is a review of an editorial on "Central Station Economy" which appeared in our issue for February 20. It will be remembered that this same journal, while defending the Welsbach light, very adroitly avoided the real questions at issue, and endeavored to concentrate the attention of its readers upon minor points not pertinent to the question. It was the case of the fits doctor over again, who used but a single remedy, and that was for fits. No matter what the patient's disease, he converted that disease into fits, and then cured the fits. With our contemporary the "main holt" is the Welsbach light. It matters not what subject it *commences* to discuss, it always brings it around in some way to the Welsbach light, for like the aforesaid physician, it thinks it is immense on its particular specialty.

After quoting freely from our remarks it says:

> Now, we have no quarrel to pick with our esteemed contemporary's figures; in fact, we think they are first-rate figures. But we should like to submit the following question:
>
> Since gas light costs 37½ per cent. less than steam-driven electric light, and, since gas-driven electric lights are cheaper still than the gas light, why don't the electric light companies make their light from gas-engines?
>
> To put this in another way, and perhaps more clearly—Since the electric companies are losing money in selling for a dollar what the gas companies are getting rich in selling for 62½ cents, and, since the electric companies could manufacture their same product, with the help of a gas-engine, for 317-743, or 42.7 per cent. of the cost incurred by their competitors, why don't they do it?

The answer is that they *are* doing it. We are speaking now of the cost of generation. There is probably not a central station in the country that could not afford to sell electric light cheaper than gas is sold if it could operate its station continuously at its most economical rate. Unfortunately, the central station manager has no such means of storing up his surplus energy during the hours of light load as is at hand to the gas engineer, hence the earning capacity of his plant is reduced to about one-third what it should be. One of the chief advantages of the gas engine is that it has no standby losses, and by its use the large standby losses of the steam boiler, which add so much to the cost of current, are obviated. In an increasingly great number of cases, not only in New York City but elsewhere, the gas engine operated dynamo in isolated plants has supplanted street service, with a consequent reduction in the cost of that service of at least 40 per cent. on the cost of gas light.

Continuing, it says:

> Is this a specimen of the executive ability that keeps electric stock at two-fifths of the value of gas stock? Since the only deduction to be drawn from ELECTRICITY'S figures is that the electric companies, by adopting gas engines, could reduce their price per candle power by 73 per cent., and then stand just as good a chance of making money as they do now, either those figures are wrong or else the electric men are— well, we won't call names.

This state of affairs does not imply a lack of executive or other ability on the part of the central station man, but is attributable almost entirely to the exceedingly variable character of the service which he is now supplying. That there can be any competition between the two illuminants with this disparity in price certainly implies an intrinsic merit in the electric light that even the cheaper cost of gas light does not overcome. This cannot be very gratifying to our contemporary, we think.

Concluding, it says:

> But this isn't all. ELECTRICITY confines its comparisons in small lights to the batswing flame. It admits that the Welsbach is at least three times as economical. So, if the electric companies are losing money in selling for a dollar what the gas companies get rich in selling for 62½ cents, how can they hope to compete with the new burner which furnishes the same thing for 21 cents? Even if the electric companies adopt gas engines and get all the gain in efficiency offered by electricity, and are thereby enabled to reduce their prices by 73 per cent., their light would still be 6 cents, or 29 per cent. higher in price than the Welsbach. "Alas! Othello's occupation——"
>
> We do not really think that the above represents the true state of the case. But in so far as ELECTRICITY'S figures, even if exaggerated, are correct in general, just so far is it evident that the inevitable goal of the course electric lighting is now running is the time when all electric current not derived from water power will be derived from gas power.
>
> Whether they sell their gas direct to the consumer of light or indirectly through the electric companies makes little difference to the gas fraternity.

Here's where the fits come in. Observe the swing around to the Welsbach light. But we must correct our contemporary—we *do not* confine our comparisons to the batswing flame nor do we admit that "the Welsbach is at least three times as economical." Doubtless it was an unintentional oversight on the part of our contemporary that caused the omission of what we really did say. It was this : "Extravagant claims have been made for the Welsbach light, but assuming the highest figures claimed, viz., 55 C. P. from 4.6 cubic feet," we still have "a ratio of 4.99 to 1 in favor of electricity." We regret that our esteemed contemporary omitted to quote these remarks, but, as we said before, we feel sure that it was an *unintentional* oversight.

But the electrical industry is fast working out its own salvation and building up industries of its own which it can supply with power during its hours of small lighting load. In this way the central stations will equalize their load lines and the electric light will be sold at a profit for less than gas light can be sold for, and we will have a light that is both cheaper and better than gas. Gas should never be burned except in connection with a chimney. The inevitable goal of electricity is to do *all* the lighting. The "inevitable goal" of gas is to be used for fuel. But we can make a gas suitable for fuel purposes much cheaper than is now made for illuminating purposes. Those wanting gas for fuel—and that is what it is best fitted for—will patronize fuel-gas companies, which our gas light companies will finally become. The gas light companies will then become serviceable adjuncts to the electrical station, and as such be useful. But as far as direct illumination is concerned—"alas ! Othello's occupation——" Words fail us here.

* * *

The Tesla Two-Phase System. In this issue Mr. Perry concludes his description of the polyphase installation at the new Westinghouse shops at East Pittsburg. It will be noticed that he has not confined himself strictly to a description of the apparatus there employed, but in order that the system of transmission as well as of distribution might be given in a connected way he has assumed that these works are at the further end of a long transmission plant, and, after having described the generators, has assumed that they have been replaced by step-down transformers. In a cursory way he has touched on the various apparatus which would be involved in this long transmission, and then takes up that which is actually employed in the distribution itself.

After an operation for several weeks of the many two-phase motors already installed, engaged in the greatest variety of service, it must be gratifying to the Westinghouse Company that their performance leaves nothing to be desired and that the reports from the motor hospital show all the beds empty. It has been claimed by Dr. Bell that it was impossible to burn out a polyphase motor. It is true that there is very little likelihood of its burning out—much less, perhaps, than with the direct current motor—but any self-respecting motor will burn out if the proper conditions are supplied. One case of the kind has actually occurred with the Tesla motor under conditions where the machine would have been condemned if it hadn't burned out. It may be said, however, that the polyphase motor is practically indestructible from this cause under any conditions which it is likely to be called upon to meet, and we only mention this instance to contradict the positive statement of an enthusiast who sometimes allows his words to run away with his judgment.

IF the rules of personal conduct and business probity which guided the late George M. Phelps had a greater number of adherents the world would be the better for it.

His thirty odd years of activity in the electrical trade brought him few enemies; yet he did not lack force in controversy nor in handling his business. Always courteous, always impressing those about him with the desire to be just, it was his good fortune and his merit to escape the bitterness which too often follows the successful man through the struggles which lead to that success. He never failed to respond liberally to the many calls for charity made upon him, and always had a hearty word of encouragement for the unfortunate. He has left a creditable mark upon his time, and ELECTRICITY extends to his intimate associates sincere sympathy in their loss.

The Situation. No officer of either the G. E. or Westinghouse Company has been found ready to state that any trade of any kind has been closed between the two companies. On the other hand, more than one has stated that nothing had been definitely agreed to, and that consequently no prediction could be made.

It is futile, therefore, to add much to what has been lately said in these columns on the fallacies of combinations.

There is no doubt that a game has been played, deeper in portent than any scheme ever hatched in the brain of Mr. C. A. Coffin. This game has been in the hands of masters, who amuse themselves only behind the double-barred doors of banks, but who nevertheless are sometimes compelled to consult those who play more in the open before they can reach conclusions.

That some plan was intended by which fresh money could be raised to place the G. E. wreck in better shape to speculate with, there is little doubt. The stockholders have been robbed almost to the point where they will call on the courts to stop the thievery, and ANY TRADE of any nature, whereby new money and new men could be pulled in would be welcomed by them. This has been the nigger in the woodpile from the beginning—a desire to float new securities. And the knowledge that ELECTRICITY was prepared to kill any such scheme at its birth has been an unpleasant fact in the situation for the schemers. We have ruined their credit once, and can do it twice or three times if necessary.

There may have been more truth than nonsense in the remarks of the financial editor of the New York *Sun* on Sunday, that the whole series of consolidation rumors had been handled to work G. E. stock up and down by two Westinghouse and one G. E. directors, who knew that no such trade could be made, but who also knew that they could make money as individuals out of the reports if properly handled.

There is no trade in sight which could result in anything but benefit to the G. E. manipulators and in corresponding injury to any legitimate interests on the other side.

The best thing to do will be to let these G. E. wreckers proceed with their own game until they have robbed the stockholders of their last dollar, even to an assessment, and until one or two of the prime movers are landed where they belong —in jail.

Under the Searchlight.

Views and Opinions on Timely Topics.

SOUND PHILOSOPHY.

The Best System Will Win.

(From the New York Sun.)

It may be hard upon the steam railroads to lose business; but it is important to the community that transportation shall be as cheap as possible. The steam people have no right to complain even if they should be driven out. For, did they not drive out of business the old stage coaches by which folks traveled, and the wagons by which goods were transported, and the horseback carriers who swept over the highways with their mail bags? Indeed, they did ; and thus they threw hundreds of men out of employment in Connecticut, besides reducing the price of horses. They did not care a copper how many stage drivers were knocked out by steam, or how many country inns were ruined by the rail, or how many stables were closed because animals were superseded by engines. Not a copper, so long as they drew their dividends and rose to the top of society. If they, in their turn, are injured by the electric people, they must take the time to think that this world is but a fleeting show, and that the whirligig of time often gives compensation for losses suffered.

* * *

WE are glad to know that Sawyer-Man lamps are again on the market, and that the price has been put at a figure high enough to encourage all makers of good lamps to refuse to meet the competition of inferior lamps like the Edison. ELECTRICITY adheres to the opinion on the lamp situation expressed a few weeks ago. The best lamps will win, if they are not sold too cheap.

* * *

THE ELECTROPOISE.

An Authority Pronounces It a Fraud.

The following letter has been received by the editor of *Bee Culture* and a copy forwarded to us :

U. S. DEPARTMENT OF AGRICULTURE,
DIVISION OF CHEMISTRY,
WASHINGTON, D. C.

Mr. A. I. Root, Medina, Ohio:

DEAR SIR : I was much interested in reading your letter of the 27th ultimo, and also in looking over the enclosure which you sent. You ask my opinion of the marked part of page 5 of the circular which you enclose. From a scientific point of view it is rank charlatanry. I should want to go no further than such a sentence to form an opinion of the merits of the invention. I do not think, however, that I could properly give an opinion on the invention itself, as I do not claim to be an expert on electrical matters. I fully agree with you, however, that it is a humbug, pure and simple. I am, respectfully,

H. W. WILEY, Chemist.

April 1, 1895.

How much more proof do the religious journals and high-class magazines need before they will be forced to abandon their present dishonorable position ?

* * *

A SAMPLE of the hocus-pocus methods which have brought the storage battery methods of this country into disrepute is furnished by the Consolidated Electric Storage Company which recently paid a dividend of 1 per cent. (quarterly) although Mr. Bracken, the president, is on record as saying that he would not give over $8 per share for the stock, while at the same time he was claiming to others that it was worth $12. It is inconceivable that this concern can be paying any dividend honestly, or for any other purpose than to humbug somebody. At the time of the recent consolidation Mr. Coffin admitted over his own signature that the Consolidated Company was a bankrupt concern, owing to the G. E. and Brush companies alone over $165,000.

* * *

Electricity would like to know how many of the companies making electric light carbons and claiming to be independent concerns are really so. The public would also like to know. Only a few of them have the courage to use the advertising columns of Electricity. This is a sure test of their independence from the control of the interests arrayed on the side of monopoly, and purchasers may well look upon the others with suspicion. The plan of owning one or more so-called independent companies is not new to the Carbon Trust.

* * *

When Dr. Depew recently commented on the Pullman strike in a manner which did not please Gov. Altgeld, the latter made a severe attack on the Doctor's reputation, stating that he did not know which end of a steer the horns belong on. Evidently Gov. Altgeld and Mr. Herbert Lloyd learned the art of controversy at the same school.

* * *

We regret to add the names of *Public Opinion* and the *Chautauquan* to the black list of morally weak journals willing for a small consideration to carry the advertisement of a flagrant and exposed fraud like the Electropoise.

* * *

We recently announced that the Boston *Advertiser* had so far fallen from grace as to be engaged in booming the barefaced Pennock swindle in its advertising columns. Another former pillar of respectability in journalism, the New York *Times*, has been doing the same thing. If these journals persist in this policy, what will their advertising space be worth to reputable concerns?

* * *

AN EXPLANATION NEEDED.

We have before us a communication from Mr. J. G. Pangborn, occupying two full pages (foolscap size) of the finest linen paper to be bought in the market. In the center of the heading is an artistic crest in blue and gold. The heading reads as follows:

COMMISSION WORLD'S TRANSPORTATION
FIELD COLUMBIAN MUSEUM.
J. G. Pangborn, Honorary Director Museum World's Railway, F. C. M., *President.*
George Wood Logan, United States Navy, *Secretary.*
Hugh T. Reed, United States Army.
Wm. H. Jackson, Colorado.
Edward Everett Winchell, New York.
Clement F. Street, Illinois.
John A. Barnes, Illinois.
Edward Hill, *Messenger.*
Lahore, India, February 9th, 1895.

Mr. Pangborn is trying to induce American manufacturers to patronize an agency which he claims to be establishing for handling exhibits at the Paris Exposition in 1900.

We quote Mr. Pangborn:

"The establishing of headquarters in Paris at the termination of the travels of the Commission in *1897*, and the ultimate constituting of the staff of the associated manufacturers of, say, four of the members—Mr. Street, the mechanical engineer; Mr. Winchell, the draughtsman and artist; Mr. Stevenson, my secretary, and myself—would be very desirable."

The headquarters is, of course, to be maintained by the exhibitors. No doubt it "would be very desirable" for Mr. Pangborn, or most anyone else, to be maintained in Paris for three years with a secretary and staff on some one else's money.

But what we would like to know is this:

What connection has Mr. Pangborn with the Field Columbian Museum? What connection has the Field Columbian Museum with this scheme? Who pays for this elegant stationery?

We suppose the Field Columbian Museum management were as much surprised when they learned of the scheme as are the manufacturing companies who receive the circulars and wonder just what the "Commission World's Transportation Field Columbian Museum" means.

It is easy to see what Mr. Pangborn means.

He is no doubt having more fun than he did when he was earning his living as G. P. A. of the Baltimore and Ohio Railroad.

While the circulars are dated "Lahore, India," replies are requested to be sent to London, care B. F. Stevens, U. S. Dispatch Agent, with whom Mr. Pangborn says he is in "constant telegraphic communication."

Who pays for the telegrams?

* * *

EVOLUTION.

BY ELECTRICUS.

In the early days each winter night,
When we lived up on the farm,
Choice pitch-pine knots served us with light
And the backlog kept us warm.
Contented we to have it thus,
No sigh escaped our lips
Till a rich man moved next door to us
And *he* used tallow dips.

Unheard of such extravagance
In all the country round,
The neighbors marked the circumstance
And on such doings frowned;
But each with envy reasoned thus,
Though words ne'er 'scaped his lips,
"We'll beat that rich man next to us
With all his tallow dips."

So pa he sold a shoat one day,
And ma she went to town
And blew the money in, they say,
On candles and a gown;
And when she came back spake she thus,
With a quiver on her lips:
"We'll show that rich man next to us
What's better'n tallow dips."

And when those candles burned that night
They made it light as day,
And our neighbor when he saw the light
Threw his tallow dips away.
He got next day some whale-oil lamps,
The first that we had seen,
But pa he sold the sow for stamps
And bought some kerosene.

This knocked our nabob's whale-oil lamps
To the middle of next week
And left him naught but to decamp
And other fields to seek.
My father bore his triumph well,
But, grown ambitious, he
Resolved the farm and stock to sell
And a city swell to be.

He bought a place in Houston street,
And there we burned coal gas
Whose constant rays each night did greet
The throngs as they did pass.
But from the windows next to ours
There came a sickly sheen,
Reminding one, by all the powers,
Of a moonlight yallery green.

My father didn't think it right
To be outdone this way,
So he put in the electric light,
Which made it bright as day;
And when we turned it on that night
He softly raised a prayer:
"Heaven help the man with the Welsbach light
Who lives next door, right there."

Our neighbor's wife grew wan and thin,
His children sick and pale,
And he himself grew lank and lean,
Though once so strong and hale;
A shadow of his former might,
They bore him in the hearse,
A victim of the Welsbach light
Which also killed his nurse.

* * *

Our Style Is Appreciated.

And It Grows More Fascinating Every Week.

(From the Baltimore American.)

Electricity has always had, and will ever have, a fascination for man.

The next G. E. report will show, we are informed, no less than $8,000,000 written off from the assets for the year, and will claim a profit of $900,000 on the year's business. The latter amount is equivalent to less than one-half of 1 per cent. on the common stock after taking care of the preferred stock and the bonds. It is understood that Mr. Coolidge has insisted that the amount written off shall be as above instead of $6,500,000 as first intended.

* * *

The Brush Electric Company's business must be booming along in a manner to compel that concern to join the ranks of Schuyler Electric et al. Five of the leading men at the works, Messrs. Phipps, Bagnall, Adams, Arnold and Cox, have recently resigned to organize a competing arc lamp business.

And still those minority stockholders stick. We guess the holders of the $500,000 mortgage will be the first to kick in earnest.

* * *

The Walker Company Did Not Want It.

As recently announced in Electricity, the Walker Company of Cleveland were awarded the contract for a 1,500 K. W. generator by the Union Depot Railway Company of St. Louis. Subsequently the Walker Company refused to accept the contract, which was taken by the next higher bidder, the G. E. Company.

COMMUNICATION.

THE UNDISCOVERED FIELD.

"Quien Sabe?"

To the Editor of Electricity.

Dear Sir: Could you believe that there is such a thing as perpetual motion? Was it not supposed that Sir Isaac Newton discovered it? Is it not supposed that electricity is an undiscovered field? I am a young mechanic who hardly knew what electricity was derived from until a few months ago, and from my knowledge gained since I see how to construct in three different ways a powerful perpetual motor. When I was a youngster I remember that when I heard of magnetism I supposed that there then was some powerful magnetic motors, but it does not seem so, for I do not know of any; but magneto-electro motors are immensely superior, and I am here in this city and I see the way to construct the marvel of modern times, and owing to my financial straits I am helpless. Talk of your Count Edison, Tesla and others—why a blind man would think of what I see. It will give power to everything, will produce heat and light, will revolutionize life, make aerial navigation a reality; and I who see it is not a count or wizard, but a bright ex-newsboy and at present a painter. If you know of any investors you may recommend them to me. I will make the agreement to supply electricity if started.

Respectfully yours,
H. T. D.

P. S.—One is magnetic. One creates its own electricity, thus making itself magneto. The other is simplicity. I have an excellent idea on aerial navigation, to work by an aeroplane lifted, propelled and steered by fans—should go by

Powerful Perpetual Motion.

An Electric Scenic Theater.

Mr. John A. Seeley's scenic theater at Coney Island, which was not completed in time to open last year, is now receiving the finishing touches and the apparatus will be installed next week. The building is located just at the head of the walk leading up to Surf avenue from the Iron Pier.

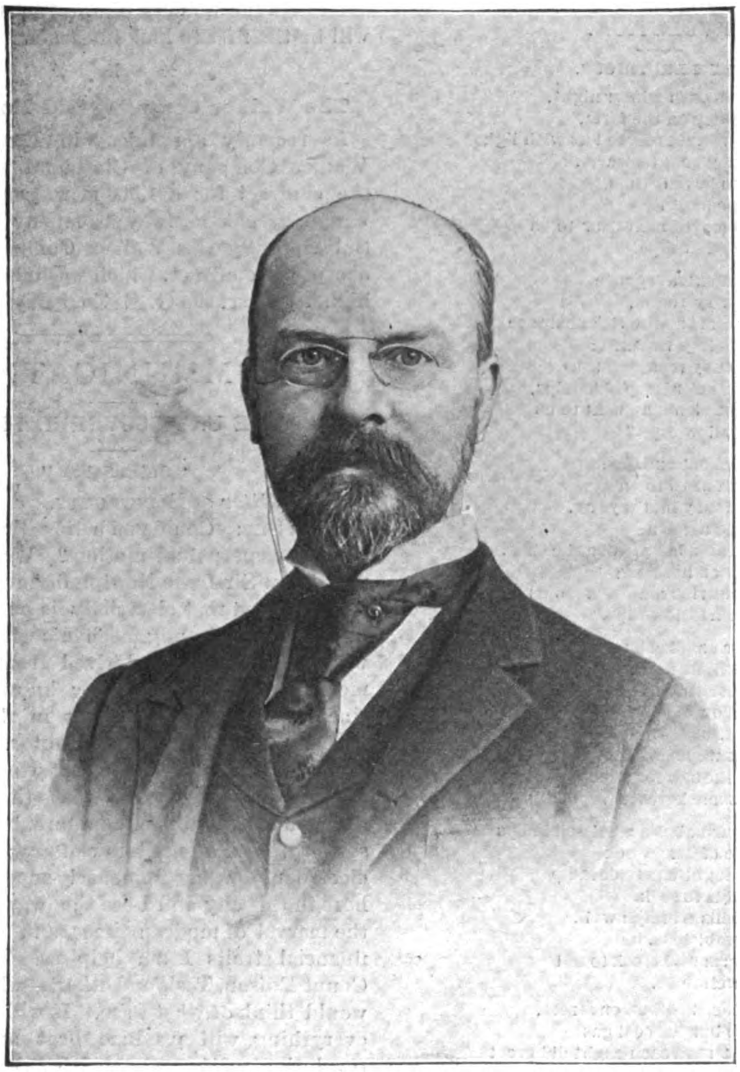
GEORGE M. PHELPS.

George M. Phelps died at the home of his sister in Division avenue, Brooklyn, E. D., on the night of April 11, after a brief illness from pneumonia, and was buried on Sunday at Troy, N. Y., his former home.

Mr. Phelps was born in 1843 at Troy, where he was educated. His first connection with the electrical business dated back to 1861, when he entered the shops of the American Telegraph Company.

Mr. Phelps's father was superintendent of this company from its organization up to the time of its absorption by the Western Union.

From 1863 to 1866 Mr. Phelps was in the auditing department of the American Telegraph Company, and from 1871 till 1879 was assistant to his father in the conduct of the Western Union Company's factory in New York. When, in April of the latter year, the telegraph company gave up its own manufacturing and disposed of its factory to the Western Electric Company, he was appointed superintendent of the factory by the latter company, which position he held till December, 1885. Early in 1886 he joined Mr. Franklin L. Pope in the conduct of *The Electrician and Electrical Engineer*, then published monthly, and acquired a proprietary interest in that journal soon after.



George May Phelps.

He was a charter member of the American Institute of Electrical Engineers, and was elected one of its managers on May 19, 1885. He served on the Council in this capacity until his election as treasurer on May 17, 1888, to which office he has been re-elected each year and which he held at the time of his decease. He had been nominated for the same office by the Council for the term beginning May 14, 1895.

When the *Electrical Engineer* was changed from a monthly to a weekly, a new company was organized and Mr. Phelps became the president, retaining the position until his death.

He had also been prominent in the affairs of the New York Electric Club. The funeral services were conducted by the Rev. John W. Chadwick, at the house where he died, on Saturday evening last, many prominent electrical men attending to pay their last respects.

Detroit's City Plant.

The municipal plant of the city of Detroit has been in operation over two weeks. There are four Western Electric 100 light arc machines running. Everything so far has given the best of satisfaction to all concerned, and Mr. Alex. Dow, the engineer who has had charge of the matter from the start, has been receiving many congratulations, in which Electricity heartily joins.

American Institute of Electrical Engineers.

The 96th meeting of the Institute will be held at 12 West 31st street, New York City, on Wednesday, April 17, at 8 P. M.

A paper will be presented by Prof. Edwin J. Houston and Mr. A. E. Kennelly, of Philadelphia, on "Resonance in Alternate Current Lines."

A paper will also be presented by Prof. W. A. Anthony, of New York City, on "Underwriters' Rules."

A meeting of Western members will be held the same evening, where the above papers *will* be read and discussed.

The Tesla Two-Phase System.

II.

EXTENSIVE USE AT THE WESTINGHOUSE WORKS, BRINTON.

The New Plant Fully Equipped with Alternating-Current Apparatus—The Most Important Installation Thus Far Attempted.

BY NELSON W. PERRY, E. M.

Returning to the power-house we find, as already stated, two 500 H. P. direct connected direct current units furnishing current at 500 volts. These are used for testing the direct current apparatus manufactured by the company and are at present operating the five electric traveling cranes, the elevators and several large direct current motors, all of which it is intended to replace as soon as possible with alternating two-phase motors. As these generators are of the standard street railway type with which all are familiar, they need not take more of our attention at this time.

Turning now to the alternating current machines on the other side of the building, we find them very different from the two-phase apparatus employed for lighting purposes at the World's Fair. In those machines, it will be remembered, there were practically two armatures revolving in a common field. The windings of these two armatures were in such relation to each other that the phases of the two currents were in quadrature with each other. In fact the World's Fair generators were really two separate machines operated on the same shaft and in a common field. The frequency of the currents was 7,200 and their voltage approximately 2,000. The present machines, which are admirably illustrated in Fig. 2 (page 170 of last issue), in many respects resemble multipolar direct current machines, except that four collecting rings replace the familiar commutator. The field magnet yoke is of massive cast-iron with inwardly projecting laminated pole-pieces, fourteen in number. The armature is single instead of double and resembles very closely in outward appearance a Gramme ring. The winding is continuous and connections are brought out at four points, 90° from each other, to collecting rings, as represented in diagram, Fig. 7, the two terminals of each diameter forming the terminals of a different circuit the phases of which differ also by 90°.

In the diagram A and B represent the collector rings of one circuit and their connections, and C and D those for the other circuit.

In three of these wires are placed automatic circuit breakers, so that in case of a short circuit between any two of the wires the circuits involved will be opened.

The windings of the armature are carried in slots in its cylindrical surface and held against centrifugal force by vulcanized fiber rods slipped into grooves in the slots just over the conductors. No binding wire is therefore employed on the cylindrical surface of the armature as is necessary when the conductors lie upon the surface.

The pole-pieces are fourteen in number and consist of laminated iron inserted into the yoke at time of casting. This insures the most perfect continuity between the two and obviates the reluctance factors due to mechanical joints. The magnetic circuit of the yoke is of high conductivity by reason of its massiveness, and the high permeability required of the pole pieces is obtained by the soft iron, and the prevention of foucault currents where they are most likely to occur is obtained by its lamination.

In the machines under discussion the fields are separately excited from a Tesla rotary transformer, illustrated in Fig. 6 (page 171).

This receives the alternating currents at the collector ring end, running as an alternating current motor and transforming them to direct currents which are taken off the commutator end for field excitation.

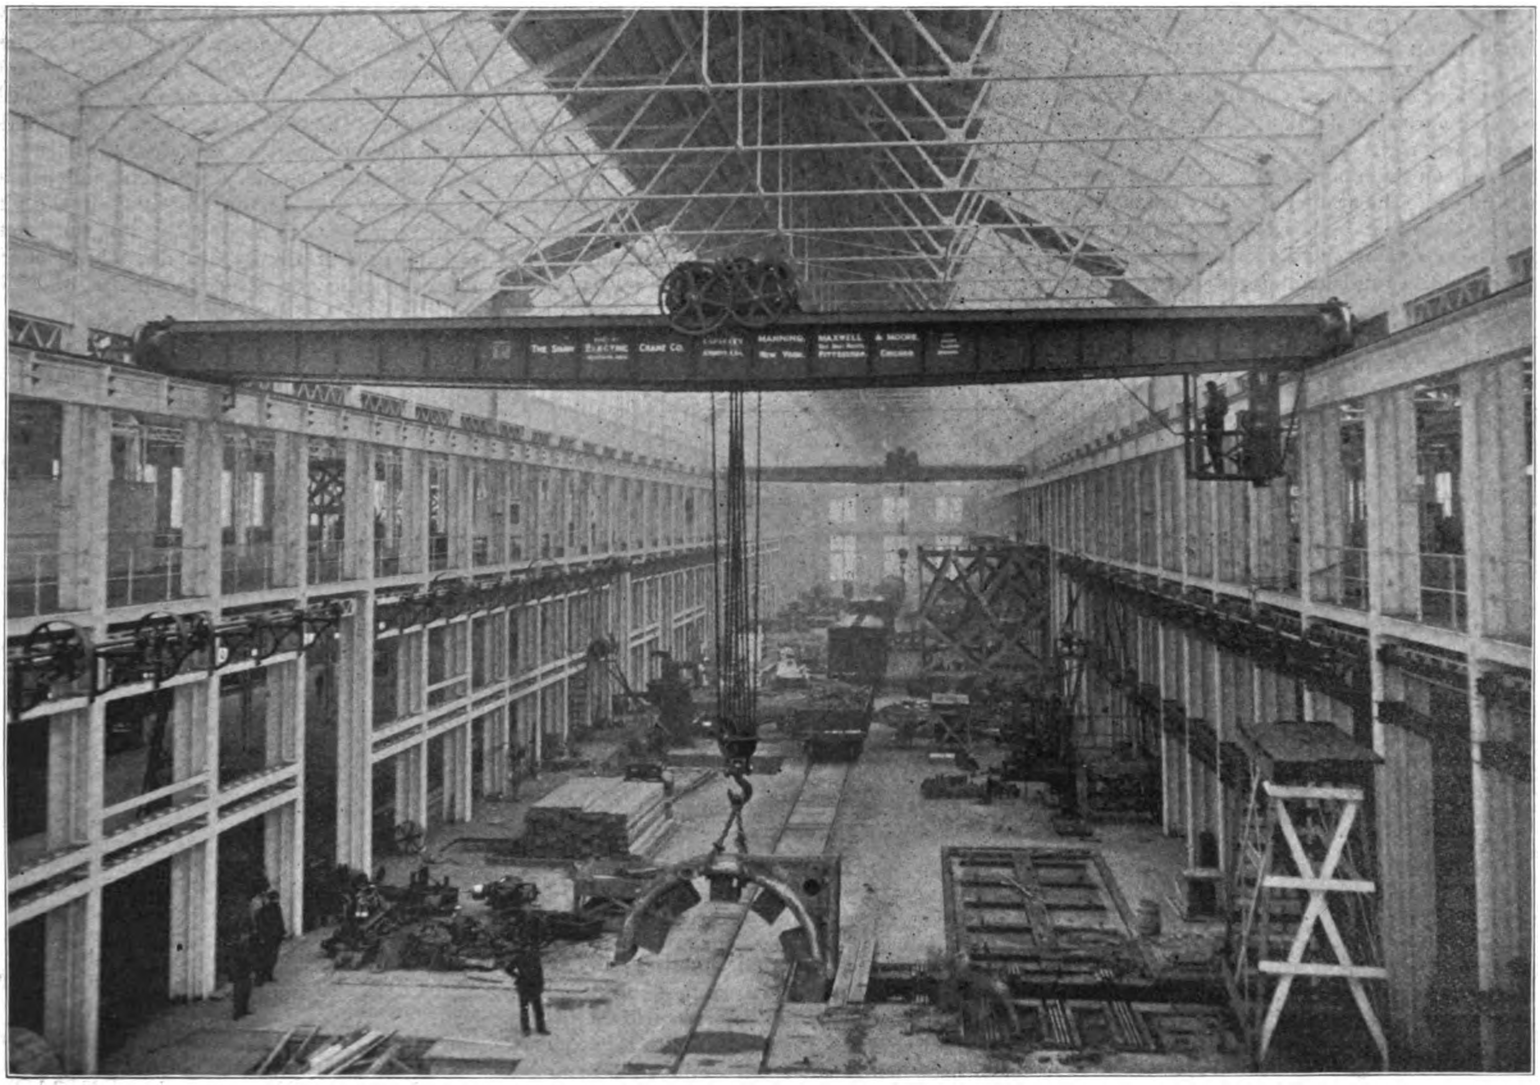
The two generators run at 220 revolutions, giving currents of 3,000 alternations—the same frequency as is to be employed at Niagara. Since in this installation the greatest distance of transmission is but about 1,100 feet, high potentials were not necessary nor desirable. The voltage employed is therefore only 230 at the generator terminals or about 220 at the motors.

Much has been written about the practicability of coupling alternators in multiple, and while it has been successfully done in a number of cases it has also failed in a sufficient number to give rise in the popular mind to a question as to its practicability. It is of the utmost importance to the central station man that he have the ability to throw units in and out of action, in multiple, as his load changes, for without this ability he must drop out in the race for supremacy. One of the points which the Westinghouse Company wished to emphasize, therefore, was that their two-phase generators could be operated in multiple, and upon their ability to operate in this way they staked the entire success of the new plant. It had not been a question with them, for it had already been demonstrated to their entire satisfaction, but the public required assurance on this point, and the object lesson which these works was intended to afford would have been incomplete had the two generators been employed on separate sets of circuits. They are therefore coupled up in multiple, and during the days when the writer saw them operating were giving a combined output of more than 400 amperes on each of the two circuits. The variation between the two machines was practically negligible, and they seemed to work in parallel in every respect as well as two direct current machines similarly connected are accustomed to do.

Where longer distances are concerned, machines giving higher potentials would be employed and step-down transformers used at the point of distribution to bring the voltage down to that suitable for motor work or lighting; or if very long distances were involved, requiring higher potentials than it would be desirable to generate directly in the armature, these same machines generating 230 volts could be used, step-up transformers employed at the power station to raise the voltage to that required for economical transmission, and step-down transformers at the point of distribution employed as before to reduce the pressure to the requirements of service.

The simplicity and efficiency of the closed magnetic circuit transformer are too well known to require remark here further than to say that they are the most efficient transformers of energy known to man. So high has this efficiency been for several years past that little improvement seemed possible or even desirable in this direction. There has been room for improvement, however, in methods of insulation against the increasingly high potentials now being used and in the dissipation of the heat energy which constitutes inevitable losses in the transformer. Theoretically a transformer working with a hot core and a cool coil would be the most efficient, but these two conditions are incompatible. They have been partially realized, however, in the Westinghouse transformer, which is illustrated in Fig. 8. This photograph shows very clearly the method of building up the laminated core around the coils adopted by this company, but the main feature to which it is desired to call attention at this time is the spreading of the ends of the coils after they come out of the iron, which affords a much better opportunity for the dissipation of the heat energy developed in the coils than any other method thus far suggested which does not at the same time dissipate the heat from the iron as well.

Still another essential to a good transformer or converter, as the Westinghouse people call it, is that it shall be proof against the breaking down of the dielectric. Where comparatively low potentials are concerned, it is not difficult to insulate against them, but when extreme pressures such as long-distance transmissions require are used, the insulation against these pressures becomes a question of the utmost importance. Tesla has shown that the air itself is a most fruitful cause of discharge across either from static or dynamic charges, and that if this be removed many of the difficulties of transformer insulation are also removed. The Westinghouse Company, therefore, exclude the air from the transformer chamber by utilizing a fluid dielectric, which has the further quality, not possessed by solid dielectrics, of repairing itself in case it does at any instant break down. The transformer shown is the latest type of the oil transformer now manufactured and used on high-potential circuits. As will be observed, no attempt is made at high insulation in the winding of the coils, they being simply wrapped in untreated cotton tape. The transformer, however, when ready for use is simply immersed in an oil



VIEW CENTRAL AISLE OF MACHINE SHOP. 30 TON ELECTRIC CRANE.

bath, the air driven out as far as possible and then connected up for service.

The Westinghouse Company was the first to appreciate the possibilities of the alternating current in long-distance transmission, and when the inventions of Gaulard and Gibbs had placed it on a commercial basis, they at once procured the exclusive right to their use. They have therefore been the pioneers in this class of apparatus, and while the system of to-day bears little resemblance to that elaborated by Gaulard and Gibbs, the system of transformation is based primarily upon the fundamental patents issued to those two gentlemen. Many other fundamental patents bearing upon this important field were also early acquired, among the most important of which are the Tesla polyphase patents, which it is claimed completely cover the whole field of polyphase transmission and distribution and which will find their highest and most extensive application in the great Niagara scheme.

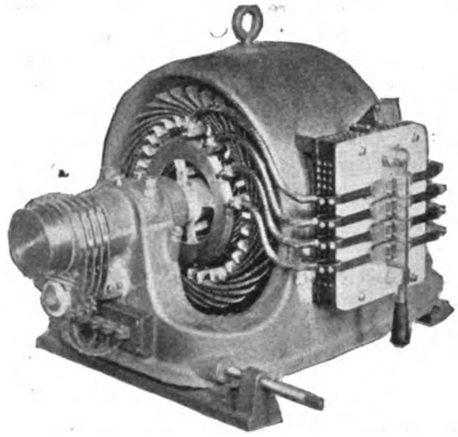


FIG. 3.—TESLA 50 H. P. TWO-PHASE MOTOR. OLD STYLE SWITCH. NEW STYLE COLLECTOR BRUSHES.

The Tesla polyphase patents upon which the Westinghouse Company base their claims of ownership in this field are the following :

May 1, 1888. Nos. 381,968—381,969—381,970—382,279—382,280—382,281, 382,282.
October 2, 1888, Nos. 390,413—390,414.
October 9, 1888, Nos. 390,721—390,820.
April 16, 1889, No. 401,520.
June 25, 1889, No. 405,858—405,859.
December 3, 1889, Nos. 416,191--416,192—416,-193—416,194—416,195.
December 31, 1889, No. 418,248.
March 25, 1890, No. 424,036.
August 5, 1890, Nos. 433,700—433,701—433,702—433,703.
January 27, 1891, No. 445,207.
June 30, 1891, No. 445,067.
September 22, 1891, No. 459,772.
December 8, 1891, No. 464,666.

Making twenty-nine patents all told, which the company believe completely cover the polyphase field so far at least as it has been developed.

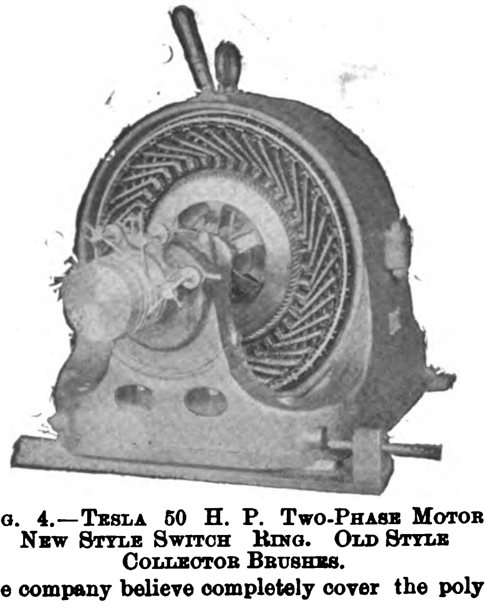

FIG. 4.—TESLA 50 H. P. TWO-PHASE MOTOR. NEW STYLE SWITCH RING. OLD STYLE COLLECTOR BRUSHES.

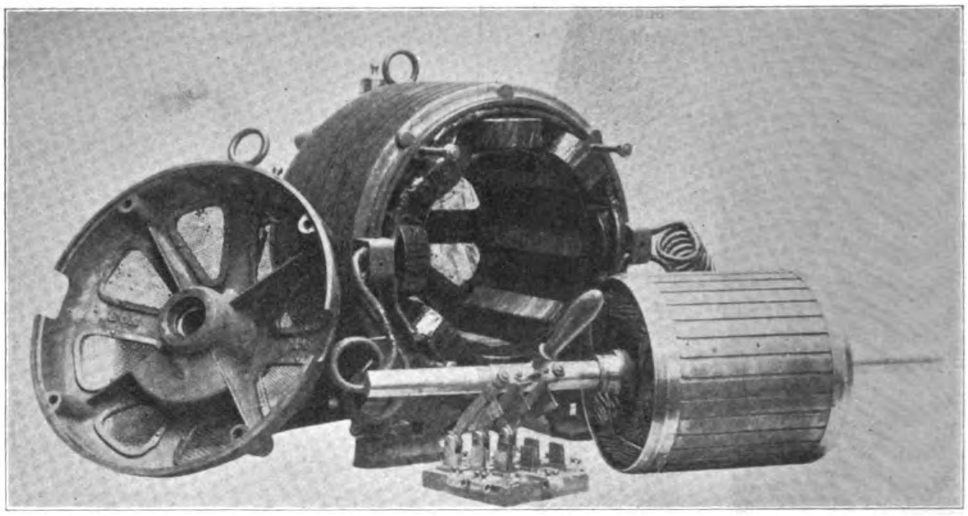
It is not to be supposed, however, that any one mind has contributed all that goes to make up the completed commercial system of to-day. Many minds indeed have contributed to the perfected system as exemplified in the plant under discussion, and while, if we were to confine ourselves strictly to this particular plant, we would necessarily pass lightly over some of these features, or not mention them at all, the description of the system as a whole would be incomplete. At the risk, therefore, of seeming a little prolix some of the more important accessories will be referred to.

Where lights are to be supplied as well as power, it is of the utmost importance to have means at hand by which the potential on the various circuits may be regulated so as to compensate for the change of losses due to variations in load. The voltmeter as usually employed in the generating station indicates only the pressure at the generator terminals and not that at the point of consumption where the variable effects of drop are encountered. In ordinary practice it has been customary to bring back small *pressure* wires from the points of distribution, by which means the pressures at those points were indicated and the proper regulation indicated to the station manager. A method of equalizing the pressures among a number of distribution points, often resorted to, has been that of connecting them all together with equalizing wires. Both of these methods are cumbersome and expensive, and have been discarded by the Westinghouse Company. In their places have been substituted the following arrangements :



TESLA 5 H. P. MOTOR, OLD TYPE.

The voltmeter is supplied by the secondary of a small converter, usually reducing in the ratio of 30 to 1 where the initial voltage is 3,300, or in a greater ratio if higher. In the voltmeter circuit there is placed a compensator. This is shown in Fig. 9, and consists of a small transformer with its primary in series with the main circuit and its secondary in series with the voltmeter circuit, and connected in such a way that the compensator pressure to the main current opposes the voltmeter pressure to an extent proportional to the loss in the conductors. The voltmeter by this arrangement, therefore, indicates the potential--not at the station, but at the point of distribution.

Now as this pressure varies it becomes necessary to have some means of correspondingly varying the station pressure. If there were but one circuit extending from each generator, this would easily be accomplished either by varying the field excitation or the speed of the armature, but in practice there are usually a number of circuits extending from each machine in each of which a different compensation is required, and the methods referred to would not be applicable. To meet such cases resort is had to the Stillwell Regulator, represented in diagram in Fig. 10.

THE STILLWELL REGULATOR.

The great value and importance of this instrument as a part of the modern complete central station equipment has been demonstrated beyond question. The principle of the instrument—as beautiful as it is simple—is that of induction. For this reason no similar device can by operated from a direct current system. It consists primarily of a converter, suitably designed, with secondary coil adjustable in length, i. e., with connections brought out from different parts of the secondary coil to a multipoint switch. By means of this switch the whole or any part of the secondary coil may be thrown in series with the main circuit, thus adding to the initial primary potential of the circuit the additional potential of the secondary coil, or a part thereof. Within the limits of the voltage thus added the potential of the supply circuit is, therefore, subject to the most delicately shaded adjustment, independent of whatever may be the potential at the alternator terminals. Consequently, it is the practice to have several supply circuits taking current from the same generator, and hence, of course, they are at absolutely the same potential. Although each circuit may be operated at a different percentage of loss, by the use of the Stillwell Regulator all lamps will be maintained at a uniform voltage and brilliancy. The attachment of a double-throw switch makes it practicable to reverse the action of the regulator and decrease instead of increase the initial potential. This may be frequently done to meet local conditions, and is an additional convenience.

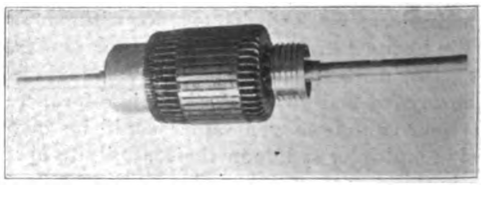


FIG. 6.—ARMATURE ROTARY TRANSFORMER.

It will be noted that this instrument simply increases the electromotive force in the circuit by a few volts. To do this it is necessary to transform but a small portion of the electrical energy passing through the regulator. The efficiency of conversion of this fraction of energy is easily 95 per cent., and it is therefore evident that the loss of energy in the regulator will be but an extremely small percentage of the total energy of the circuit. For example, at full load a 100 ampere regulator, designed to raise the initial potential 10 per cent., would receive at the terminals of its primary coil 10 amperes at 1,000 volts, and at the terminals of its secondary coil would deliver 100 amperes at 100 volts, less any losses suffered in conversion. These losses, being the same as those of a standard converter of equal capacity, aggregate not to exceed 5 per cent., i. e., 500 watts. The total energy supplied to the circuit by the generator being 110 amperes at 1,000 volts, i. e., 110,000 watts, the percentage of loss is therefore .00455, or less than ½ per cent.

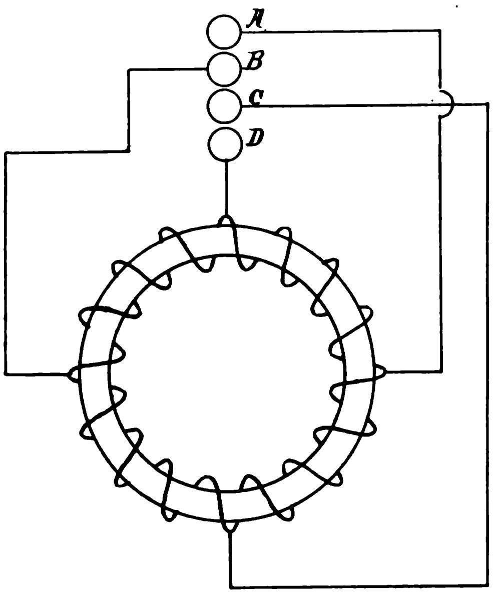

FIG. 7.—DIAGRAM OF GENERATOR ARMATURE CONNECTIONS.

The extreme flexibility supplied by the use of the regulator is illustrated by an example which occurs almost daily in practice. Let us assume a small station operating under ordinary conditions with, say, a loss of 2½ per cent. in its feeders and 1 per cent in its mains, the territory supplied being within a radius of one mile from the station. Let us further assume that there is a point two and one-half miles distant where an additional 500 lights can be secured. It would evidently not pay to erect a special alternator to supply this number of lights, and yet to supply them from the same alternator sufficient additional copper must be put into the new circuits to reduce the losses over the greater distance to those already incurred in the shorter circuits. This also would prove uneconomical and the station manager would find himself confined to a choice of three undesirable methods: 1st, to install a new alternator for the 500 lights; 2d, put in a sufficiently heavy wire to maintain the same loss at the greater distance, and 3d, abandon the idea entirely of supplying the new customers. I do not know whether dilemmas usually have three horns, but this one seems to have and they all promise to be equally uncomfortable to sit upon. The regulator, however, comes to the station manager's assistance in this way: Assuming an average of $\frac{1}{10}$ ampere in the primary line for every 16 C. P. lamp on the secondary circuits and a 10 per cent. Stillwell Regulator to be attached to the new circuit, it is immediately possible to raise the initial electromotive force 10 per cent. above the electromotive force of the other circuits supplied from the same dynamo, and to therefore allow an additional loss of the same amount on the line. The line cost for supplying these lights by this means (including the cost of the regulator) would be only about one-third what it would were the extra copper otherwise required employed. It also effects economies in operation and renders possible much better service by placing in the hands of the station manager a most perfect means of independent regulation of the various circuits extending from the same dynamo.

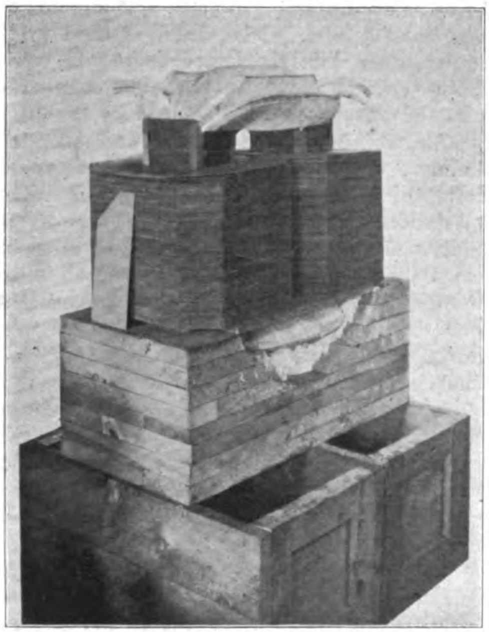

FIG. 8.—OIL TRANSFORMER PARTLY BUILT UP.

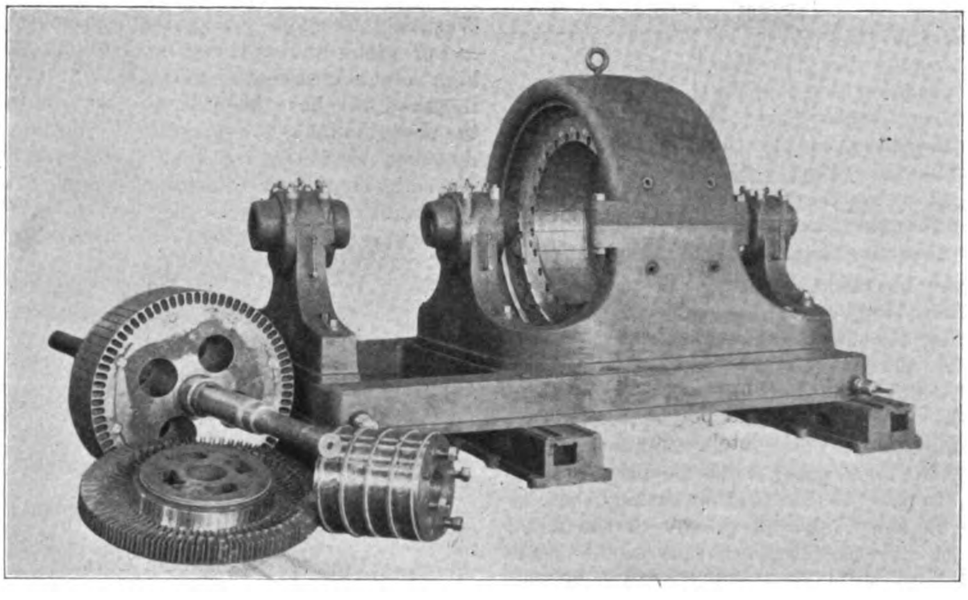

TESLA 300 K. W. MOTOR, WORLD'S FAIR TYPE.

In the regulators as now put on the market, the secondary is divided into small sections, each of which has an electromotive force equal to 1 per cent. of the primary. Any number of these sections may be placed in series with the supply circuit, and thus with standard apparatus the variations in pressure at the point of distribution may be compensated for through all variations in load within less than 1 per cent.

All long lines of overhead wire, and particularly such as traverse mountainous sections, are subject to violent atmospheric conditions which if not provided against in some efficient manner are liable to result in the destruction of the machinery at both ends of the line. The popular belief is that these destructive effects are due to lightning, but while they are apt to occur most frequently in sections of country where severe thunder-storms prevail it is doubtful if the lightning itself ever, or at least frequently, actually strikes the wires. The so-called lightning strokes on circuits are now known to be chiefly inductive effects, due to sudden changes of potential of the earth or clouds due to lightning flashes occurring not necessarily in the immediate proximity of the circuits, but which by inductive effects set up electrical surgings in the wires. These surgings if they reach the transformer or dynamos are liable to cause disruptive discharges across the insulation which may lead to its destruction. It is not the disruptive discharge, however, that does so much damage, as it is the dynamo current which, having had this path opened to it by the disruptive discharge, follows it. An effective lightning arrester, therefore, has two distinct offices to fill: 1st, to offer an easier path for the surgings than that through the coils of the machinery whereby it may be drawn off the line, and second, to prevent the passage of the dynamo current over the same path that the disruptive discharge has opened for it. The old idea was that the first of these functions was fulfilled when a grounded conductor was separated by a short air-gap from the circuits to be protected, and the second by providing some mechanism, either mechanical or magnetic, by which the arc which followed might be broken instantaneously and the normal air gap re-established for subsequent protection. Experience has taught, however, that these electrical surgings do not seek to leave the wires with equal force at all points and that they will frequently pass by a number of short air gaps and then find the ground through a much longer and apparently more difficult path. The reason for this is now well understood and is implied by the name by which I have

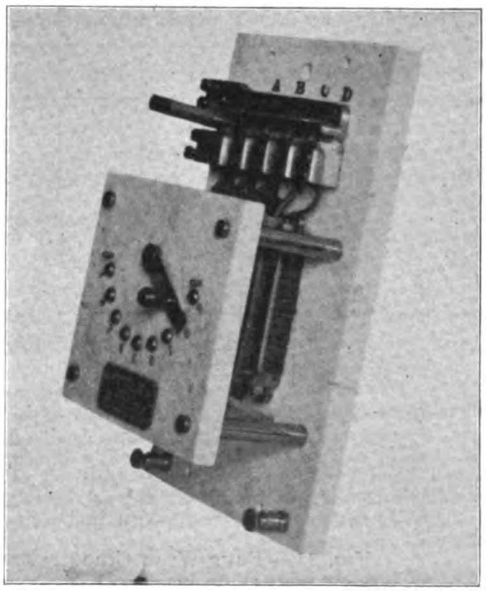

FIG. 9.—COMPENSATOR.

described them, viz., surgings. If an air gap be provided where the crest of the wave happens to be, a discharge will take place, whereas similar air-gaps, or even shorter ones, would be passed by by the same surging if they happened to be situated at any other point than where the crest happened to be found.

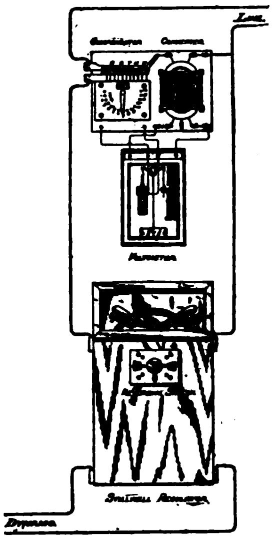

FIG. 10.—STILLWELL REGULATOR.

Mr. Alexander Jay Wurtz of the Westinghouse Company has made, under their auspices, a very exhaustive study of the phenomena of so-called lightning discharges on overhead circuits, and has discovered a method by which the lines are afforded almost absolute protection from these dangers. The basis of this discovery is that of a non-arcing metal which, when employed as the terminals of an air gap, permits the disruptive discharge to pass but immediately extinguishes, by virtue of some inherent quality of the metal itself or its vapor, the arc that would otherwise follow. In his completed arrester he employs seven cylinders of the metal—each one inch in diameter, and three inches long. These are mounted side by side, separated from one another by $\frac{1}{32}$ of an inch. The central one is connected to the ground while the two outside ones are connected to the two sides of the circuit. With these metals and this arrangement it has been found impossible to start and maintain an arc when they are separated by an air gap of this size, but strange to say, where the gap is longer—say half an inch—the arcing is said to be very vicious. In recognition of the value of this discovery of non-arcing metals and their application to the protection of circuits, the Franklin Institute of Philadelphia awarded to Mr. Wurtz the John Scott Legacy premium and medal. These lightning arresters are placed at such frequent intervals along the line that some one or more of them is sure to be in the proper position to draw off the charge at the crest of the wave. The arresters are also placed in the stations at both ends of the line. As showing the frequency of these discharges in some localities, an instance is cited in the experience of a line at Telluride, Colorado, when forty-two discharges of the lightning arresters were observed in as many minutes, any one of which might, if not thus provided for, have damaged or destroyed the machinery at one or the other end of the line.

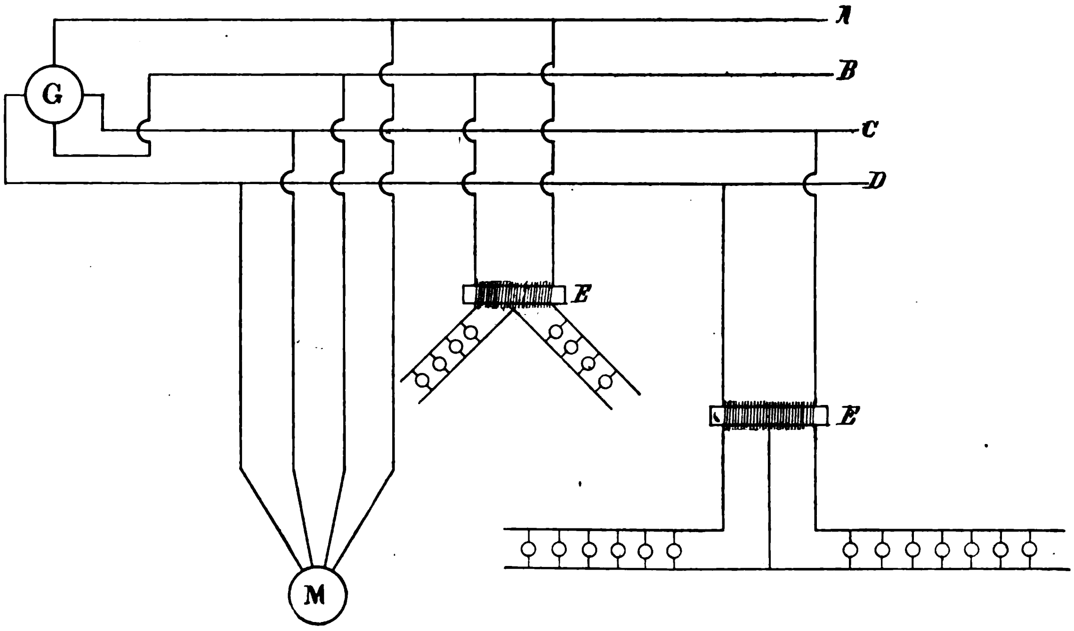

FIG. 11.—FOUR-WIRE CIRCUIT WITH MOTOR AND LIGHT CONNECTIONS.

The above digression has been indulged in to call attention to some of the accessories to a transmission plant installed on the Westinghouse system. This is scarcely pertinent to the subject in hand, but we may consider that the Westinghouse shops are located at the further end of a long line of transmission, and that the high voltage transmission currents of 5, 10 or 20 thousand volts have been transformed down in the power house to 230 volts for distribution, the dynamos previously described being simply replaced by step-down transformers, and we have the conditions exactly as they would be if the shops were actually hitched on to Niagara or any other distant source of power. The switchboard would remain as it is, and from it would run, as they do now, the four circuits—two for each of the two-phase currents.

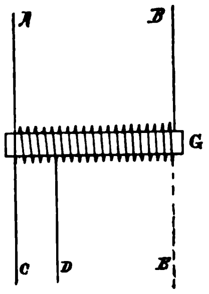

FIG. 12.—BALANCING COIL.

At Pittsburg these wires are carried overhead on insulators to the various buildings where power and light are required.

Fig. 11 shows the methods of distribution and the manner of taking current off from the circuits both for motors and light. It will be observed that the lights are taken off of both circuits indiscriminately. Usually, it would be better to divide the lights about equally between the two circuits, for the reason that where all the motors used are two-phased motors, as in this establishment, the only chance for unbalancing the circuits is by overloading one circuit with lights at the expense of the other. Some writers have held that this unbalancing of the circuit would introduce undesirable complications in the operation of the apparatus. There seems to have been no foundation for these fears, for the irregularities do not develop in practice. The Westinghouse Company have put the system to the severest test of fully loading one side with lamps and operating them with no load on the other side. The difference observed under these conditions between the two sides was only 4 per cent.

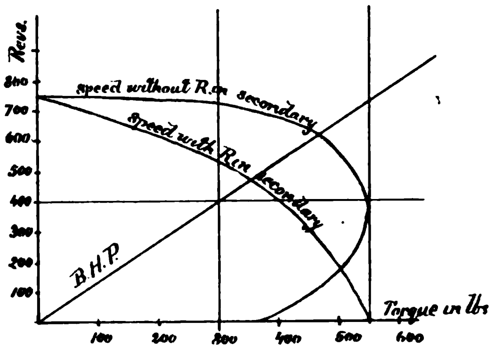

FIG. 13.—CURVE OF TORQUE.

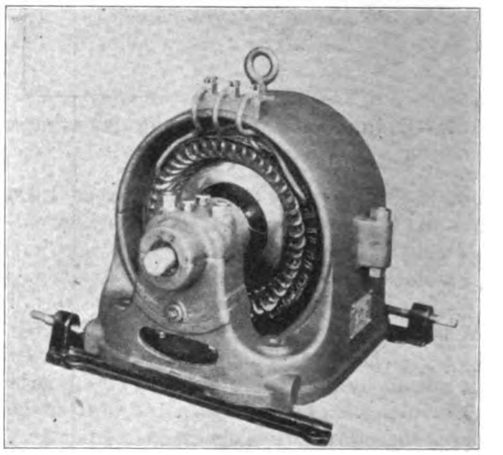

FIG. 14.—TESLA THREE-PHASE MOTOR.

THE BALANCING COILS.

It will be observed in the diagram (Fig. 11), that the lights are taken off of either circuit, between which there is a difference of potential at this point of about 220 volts. The lamps require but 110 volts. The usual method would require either that the lamps should be wired two in series or that the potential be reduced by means of a transformer. Instead of the usual transformer with separate primary and secondary windings, the balancing coil is here used. While the functions of this coil are doubtless well understood by many of the readers of this paper, it may be well for the benefit of others to describe it in detail. In Fig. 11 this coil is represented by E, and in Fig. 12 on a larger scale by G. In the latter figure, A and B are the two sides of the 220 volt circuit connected to the terminals of a coil with iron core G. If there were no secondary coil, or if the secondary coil were open, this coil would act by self-induction as a choking coil, and no current could pass from A to B. For the purposes of illustration I have represented this coil as having twenty complete turns. If to one end the wire C were attached, and another one D were attached to the fifth turn, then the twenty turns would act as a primary and the five as a secondary—the currents in the two being in opposite phase, and the reduction of potential between these two wires would be from 220 volts to 55. If now a third wire E were attached to the other end of the coil, the whole coil would again act as a primary to that portion of the coil between D and E as a secondary—in this case fifteen turns—and the potential between these two wires would be $\frac{15}{20}$ of the primary voltage, or 165 volts. By this means it is possible with a single coil to divide up the voltage into two or more parts by including between the secondary wires the proper proportions of the coils to effect the desired reduction. It is in fact a transformer, but one of exceedingly simple and economical construction, and for distributing a 220 volt current to 110 volt lamps is made use of by connecting a neutral wire into the center of the coil, and from this elementary three-wire circuit taking off the two-wire circuits at convenient points. Since the coil is equally divided between the two circuits, the electromotive force of the primary is also equally divided between the two branches, and there is obtained 110 volts in each branch. If it were desired to take off four circuits of 55 volts each, for arc lamps or other purposes, the coil would be divided into four equal portions, or any other portion of the primary voltage could be obtained in the secondary by simply including between the two wires of the secondary the proper proportion of the primary coils.

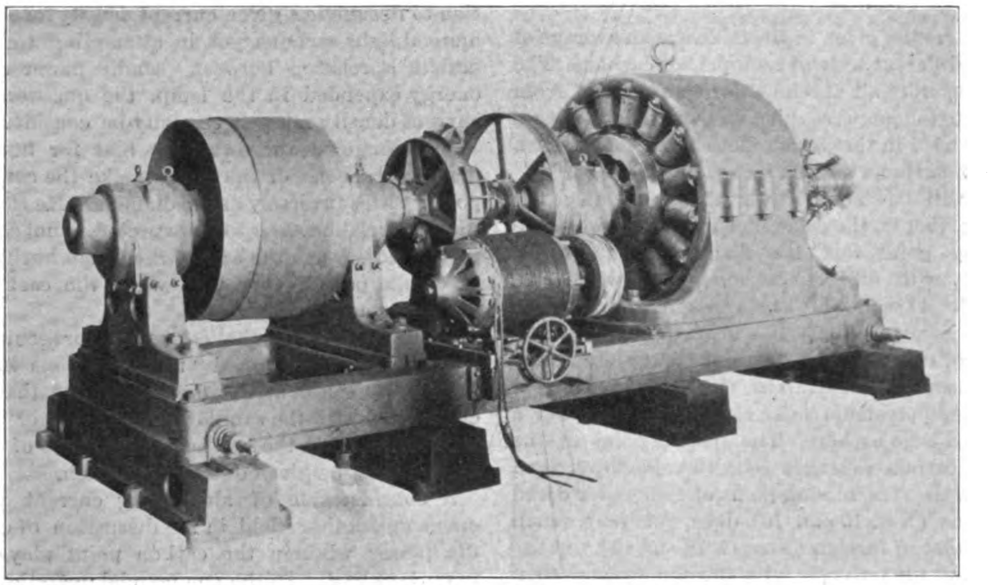

FIG. 15.—250 H. P. SYNCHRONOUS AND STARTING MOTOR.

The advantage of this arrangement over the two-coil transformer for this purpose is its simplicity and the economy both of copper and of attendant copper losses.

TWO-PHASED MOTORS.

The motors' currents are taken off the two circuits as shown in Fig. 11, the connections being made as shown at M. The alternating current motor is in reality a transformer so constructed as to permit of relative motion between the primary and secondary coils. If either one of these be fixed in position, the other becomes the rotating part, and from one point of view it is entirely immaterial which is made the stationary and which the rotating part. Carelessness in the use of language has accustomed us to refer to the rotating member of a motor as the armature, but strict scientific accuracy forbids such indiscriminate use of the term. The Westinghouse Company are therefore to be commended for introducing a more accurate nomenclature, which is bound to find general acceptance as soon as it is better known. At the Westinghouse Works the word "armature" is no longer used when speaking of the two-phased motor, but it is described as the "rotating primary" or rotating secondary" as the impressed E. M. F.'s are led into the rotating or the stationary part. There is nothing in direct current practice to indicate the advisability of introducing resistances into the armature circuit, and they are avoided as far as possible except for starting purposes, when their function is simply prevent too great a rush of current. These resistances are not only wasteful, but actually cut down the starting torque of the motor by the exact amount by which they cut down the current. The starting resistance in a direct current motor is therefore the lesser of two evils, because nothing could be worse for the motor than to have its armature burn out, as it most surely would do if started under heavy load without the resistance. It has been found, however, that in the polyphase motor the starting resistance has performed a valuable service, viz., it *increases* the starting torque of the motor.

For the purpose of illustration the diagram, Fig. 13, is given. These curves are not intended to be correct, but merely to illustrate the point which it is desired to emphasize. If a polyphase motor were started without a resistance in its secondary, the curve determined by torque and speed would be something like the upper one. The torque would be comparatively low at start, but reach a maximum in this case when the speed had reached 400 revolutions per minute.

Now the torque of that particular motor can never exceed this maximum, but the position of the maximum may be made to come anywhere on the vertical line passing through this point desired and will descend as the resistance in the secondary increases. If this resistance be just right, the point will be brought down to the intersection of this vertical line with the line of no speed, or in other words, the motor will have its maximum torque at starting. Under these conditions the curve will take the form shown in the lower of the two curves, which is an actual curve taken from a 40 H. P. 220 volt two-phase motor with old style switch.

The resistance which performed this valuable function of giving the motor its maximum torque at starting in addition to preventing a too great rush of current at that time, will, after speed has been attained, be a detriment, so that means are provided by which it can be then cut out. To facilitate the cutting in and out of the starting resistances the larger sized motors which are likely to be called upon to exert a heavy starting torque are usually made with a stationary secondary—the current from the line being led to the revolving part by means of brushes bearing upon four rings on the shaft. Fig. 3 represents a motor of this kind. In this the brushes are of an improved type, but the switch is one that, although still used, is being superseded by another to be described later. In the old style, Fig. 3, all of the windings of the secondary are in series with each other, and when the switch is open are also in series with the starting resistances. When speed is attained these resistances are simply short-circuited by closing the switch, as shown in the engraving. The new style switch shown in Fig. 4, is considered a great improvement on this and is arranged as follows: At starting each conductor of the secondary is in series with a small resistance and with every other conductor. By means of a closed copper ring and sliding contacts connected with it, by a movement of the controlling switch, not only are the starting resistances thrown out of circuit but all of the conductors of the secondary are thrown from a series arrangement into a parallel one, being short-circuited on this ring. This not only greatly reduces the internal resistance of the secondary windings over that which is possible by the previously described arrangement, where at best they are in series, but leaves each of the short conductors free to act independently irrespective of the disturbing influences which the others might have upon it were they all in series. In Fig. 4 the brushes are of the old style. No photograph has yet been taken of the improved type motor, and it cannot therefore be shown here, but if the brushes shown in Fig. 3 were substituted for those shown in Fig. 4 the latter would then accurately represent the latest development of the Tesla two-phase motor with revolving primary.

For the smaller sizes, where a starting torque is not so essential, the primary coil is made the stationary part and the secondary coil the revolving part. The primary is a continuous winding of the drum type with connections brought out to binding posts from the points 90° apart. The secondary consists of a laminated iron cylinder into whose surface are sunk copper bars of large section, forming elements of the cylindrical surface. These copper bars, which form the windings of the secondary, are simply short-circuited at both ends on heavy copper rings, as is the case in Fig. 4 when the latter has reached speed. There are no collecting rings, brushes or other means of connection between the rotating part and the outside circuit on motors of this type, and although they do not attain a maximum torque until considerable speed is reached, they still have an initial torque sufficient to start under a very considerable load.

While the two-phase motor is the only kind at present in use in these shops, the company also makes several other types, one of which, the three-phase motor, similar to those employed in the Lauffen-Frankfort experiment, is shown in Fig. 14. Another type is the single-phase synchronous motor, such as has been in successful use for about four years in the long mining transmission plant at Telluride, Col. This latter type will not start under load, but when brought up to a speed synchronous with the generator it will then take the load and maintain it without further attention. In this motor the fields are excited by a direct current derived from a second winding parallel with the main coils around the teeth of the armature. This is commutated and led to the field coils.

A motor of the synchronous type requires an auxiliary device for starting, however, which is usually a small motor—a special modification of the Tesla type. Fig. 15 is a photograph of a 250 H. P. synchronous motor, with the Tesla starting motor and friction clutch, installed at Telluride some years ago and still in successful operation.

With this somewhat hasty and necessarily incomplete description of the New Westinghouse Works this paper must be brought to a close. Much that would be of interest has been passed over lightly or omitted entirely, but enough has been said probably to verify the opinion expressed in the beginning, that this is the most interesting, and from many points of view the most important, electrical installation thus far attempted.

ARC CARBONS AND THE RATING OF ARC LAMPS.

BY L. B. MARKS.

At the last Convention of the National Electric Light Association a special committee on the rating of arc lamps submitted a report which was adopted and ordered printed in full in the Standard Rules of the Association. The report reads as follows:

> "Recognizing the difficulty, if not impossibility, of measuring with any degree of accuracy the illuminating power of the arc lamp, and the great necessity for a more precise definition and statement of the obligation of the producer of electricity for illuminating purposes to the consumer thereof; be it
>
> "*Resolved*, That in the opinion of this Convention what is ordinarily known as a 2,000 C. P. arc lamp is one requiring on the average 450 watts for its maintenance, measurements being made at the lamp terminals where no sensible resistance is included in series with the arc; in case such resistance is used it must be excluded in the measurements of the voltage."

This report naturally suggests the inquiry as to how far the candle power produced depends upon the watts consumed. In the present paper attention will be confined to the part played by the arc carbon in this important relation.

It is, of course, well known that the so-called 2,000 C.P. arc really gives a mean candle power of only 300 to 600, the candle power at the angle of maximum illumination seldom being greater than 1,200 and often as low as 700. In an elaborate series of comparative tests made by the writer* several years ago there was found to be a variation of over 80 per cent. in the candle power of commercial arc light carbons consuming the same energy. Quite recently Prof. W. M. Stine† has reported on a number of tests, the results of which show a variation of about 30 per cent.

The difference in the quality of arc carbons is well brought out in the following table, in which values are given for the hissing point and the flaming point of various American and foreign products respectively:

Number.	Structure.	Diameter (inches).	Basic Material.	Process of Manufacture.	Hissing Point (Volts).	Flaming Point (Volts).	Range (Volts).
1.	Solid	½	Petroleum Coke	Molded	43.6	71 3	27.7
2	Solid	½	Petroleum Coke	Molded	48.2	79.0	30.8
3	Solid	7/16	Petroleum Coke	Molded	45.7	79.7	34.0
4	Solid	[illegible]	Petroleum Coke	Squirted	51.3	62.7	11.4
5	Solid	½	Petroleum Coke	Squirted	47.3	75.0	27.7
6	Solid	½	Lamp Black	Squirted	47.2	70.8	23.6
7	Solid	7/16	Lamp Black	Molded	43.0	67.3	24.3
8	Solid	7/16	Lamp Black	Squirted	43.7	76.8	33.1
9	Solid	7/16	Gas Black	Squirted	46.	70.7	24.7
10	Solid	7/16	Gas Black	Molded	41.3	74.3	33.0
11	Solid	7/16	Not Ascertained	Squirted	41.7	75.3	33.6
12	Solid	7/16	Pure Coke	Molded	53.7	73.7	20.0
13	Solid	7/16	Pure Coke	Molded	52 0	71.5	19.5
14	(+), 1/16 hole (−), solid	½	Petroleum Coke	Squirted	42.8	60.7	17.9
15	(+), cored (−), solid	(+), [illegible] (−), ½	Petroleum Coke	Squirted	35 0	61 7	26.7
16	(+), cored (−), solid	½	Petroleum Coke	Squirted	31.3	58.7	27.4
17	(+), cored (−), solid	(+), ½ (−), 7/16	Not Ascertained	Squirted	31.3	70.7	39 4
18	(+), cored (−), solid	7/16	Not Ascertained	Squirted	32.3	66.3	34.0
19	(+), cored (−), solid	(+), ½ (−), 7/16	Not Ascertained	Squirted	31.7	71.3	39.6

Table showing the hissing and flaming points respectively for mean current, 9.5 amperes. Measurements by Wm. C. Hubbard.

In order to determine these values a pair of carbons was placed in a lamp and burned for twenty to thirty minutes. After the point had been well formed the carbons were gently brought together until the arc hissed. A voltmeter connected to the terminals gave the potential difference. The lamp was then adjusted for a silent arc and the mechanism so arranged that the rod was held rigidly. The carbons were then allowed to burn away until they flamed, the voltmeter being carefully watched meanwhile. Before the flaming point was reached the instrument would invariably fluctuate, due to "jumping" of the arc. At the flaming point there was a marked drop in the potential, as indicated by a voltmeter. Great care was taken to secure perfect alignment of the upper and lower carbons.

The results given in the table are an average of three different tests of each pair of carbons. The carbons were all intended for a current of from eight to ten amperes, nine and one-half amperes being used in the tests. The total length of a pair of carbons was ten inches in each case.

It will be noted from the table that the *range*, that is, the difference in volts between the hissing point and the flaming point, varies greatly with different carbons; thus, while carbon No. 4 (see table) has a range of only 11.4 volts, carbon No. 3 has a range of 34 volts. Both of these carbons are sold by representative American manufacturers, the former being a squirted petroleum coke carbon and the latter a molded coke carbon. The hissing point of the cored carbon averages over 10 volts lower than the solid. The hissing point of American cored carbons (Nos. 15 and 16) does not vary much from that of foreign (Nos. 17, 18 and 19), but the range of the latter is fully 10 volts greater than that of the former, and exceeds that of any of the American products tested, cored or solid. In the case of some makes of cored carbons not recorded here it was impossible to measure the hissing point with any degree of accuracy, because of the deposition on the negative of small portions of the core thrown out by the positive at low potential differences. Carbons Nos. 11, 17, 18 and 19 in table are of foreign manufacture, all the others being home products.

The amount and nature of foreign matter in a carbon have much to do with the commercial efficiency of the latter and determine to a large extent the range of the carbon.

It has been the desire of central station men to obtain, and the aim of the manufacturer to produce, an absolutely pure petroleum coke carbon, thinking that this would, in a large measure, solve the candle power question so far as uniformity is concerned. The writer is of the opinion, however, than an absolutely pure coke carbon, if such could be commercially manufactured for arc lamps, would not meet the requirements of central station practice to-day. Carbons 12 and 13 (see table) are taken from two batches made with special reference to purity. It will be noticed that one of them hissed at 53.7 and the other at 52.

To be operated at maximum efficiency these carbons would require more than 55 volts at normal current and under no conditions in practice would they give satisfactory service at less than 55 volts average—fully five volts higher than that of good commercial carbons. In connection with the potential difference required for maximum candle power in a given case, it is interesting to refer to a test reported by Prof. H. S. Carhart, in which a pair of commercial carbons designed for use on full arc circuits showed a maximum efficiency at about 55 volts. These carbons at 10 amperes and 45 volts gave 450 candle power.

Thus, it is of the utmost importance to the carbon manufacturer to test not only the range of his carbons, but also the voltage at which they give maximum efficiency. The importance of steadiness in arc lamps has been very well shown by the introduction of cored carbons. Here, again, we are confronted with the question of candle power in relation to the consumption of energy. If we assume that a 450 watt arc gives nominally 500 candle power with efficient solid carbon sticks, we must make an allowance of at least from 15 to 20 per cent. for reduction in candle power for the same energy substituting an efficient cored carbon stick. Yet, for indoor illumination the consumer is better satisfied with the cored carbon than with the solid.

Reference has already been made to current density. It would be entirely out of the question to designate a given current density for commercial light carbons, yet, in attempting to formulate a relation between candle power and energy expended in the lamp, the question of current density must necessarily be considered.

Schreihage* deduced the law that for homogeneous carbons of the same make the candle power varies inversely as the diameter. He states that this relation, as is to be expected, is not completely satisfied in the case of the mean horizontal candle power, especially when the carbons are very small or very large.

When we consider that as a means for securing long life, flat carbons and "twin" carbons have been more or less used, we are reminded that in connection with the available candle power per watt expended in the arc lamp the shape of the carbon must be given due consideration.

A consideration of alternating current arcs opens up another field in the discussion of candle power wherein the carbon point plays an important part. In the commercial operation of alternating current arcs, cored carbons are almost exclusively used. The constituency of the core has much to do with the efficiency of this type.

The comparison of the candle power of a commercial alternating current arc with that of a direct current arc consuming the same energy, as measured at the carbon points, shows that the former gives less illumination than the latter. So important is the relation of the carbon point to efficiency of the alternating current arc that the substitution of a solid carbon for a cored carbon in this form may reduce the candle power and decrease the efficiency to such an extent as to make the lamp unmarketable.

Thus far we have discussed arcs which burn with free access of oxygen. In the case of inclosed arcs, or those which are operated in small bulbs, to which the air has very limited access, the conditions that govern the relation of watts to candle power for the open air arc are more or less modified. With inclosed arcs, purity of the carbon is very important, and in some applications of these arcs the objections which stand in the way of commercial utilization of pure carbon electrodes in open-air arcs do not apply.

The importance of details in the manufacture of carbons cannot be overestimated in the consideration of this subject. With the carbon maker rests the task of supplying a uniform and efficient product; but even with the best carbon product, it would seem advisable to discard the term "2,000 candle power," or "1,200 candle power," as applied to arc lamps.

Measurement of the wattage, provided for in the resolution of the Committee on the Rating of Arc Lamps, appears to be the true solution of the problem. The central station manager will undoubtedly find it to his interest to furnish good carbons, and if he demands them the carbon manufacturer will supply them. To quote Capt. William Brophy: "The sooner you sell your light as power, the sooner this trouble will end; and I advise every man in the future to sell his lamp at 450 watts, or whatever is necessary, and bury out of sight the term '2,000 candle power.'"

Notes on Recent Electrical Engineering Developments in France and England*—III.

Discussion.—(*Concluded*).

As to the plant in Brighton and the question of how they do the switching, I will say that in that instance the different sections I referred to are somewhat like the spokes of a wheel, and there are only about four or five such switching points and they do, in that instance, thus far control them by hand. That is, the operator goes and throws the switch and then goes to another point. But methods have been devised by which they can be handled from the central station automatically, and if there were any sufficient reason for it at Brighton it would have been done there, as they were fully aware of the method and its feasibility.

As to the underground system at Newcastle, the conductors are not lead covered, as I remember the matter, but are covered, I think, with jute or some similar material, and the air is chemically dried by being passed, I think, over chloride of lime.

As to why the cost of small dynamos and motors is higher in European practice than here I do not know, but I am inclined to think that one of the reasons is that in this country the present popular method is for the manufacturers to bid on the machine delivered f. o. b. without any further work done in connection with it, and consequently there is very little chance for argument one over another if the machines are very good and the competition is very keen, whereas the method abroad is for the man who builds it to install it. In other words, the men who are manufacturers are generally electrical engineers, and they build and wish to install their own machines, and consequently do not care to bid so low on the dynamo alone.

One of the speakers mentioned that there was no reason why there should be any more difficulty in the ordinary locomotive in taking care of the steam and using it economically in the cylinder and delivering it rapidly and exhausting it properly than there would be with the Heilmann locomotive. But I call attention to the fact, that while it is theoretically conceivable that we should have a type of valves independently controlling the admission and exhaust in the ordinary locomotive such as we have on stationary engines, we do not have them. It has been tried and retried and they have stuck to the simpler type of Stephenson link and slide valve, because the additional economies obtained by the use of the higher class of valve motion did not compensate for the additional complications introduced, which, however, does not apply at all to a steam engine placed above on a platform in which the most refined mechanism can be used to the best advantage.

I would like to call attention to one thing that I do not think I mentioned in the paper, and that is that by actual test by the engineer of the Chemin de Fer de L'Oest, who conducted the test of the Heilmann locomotive, they did operate the Heilmann locomotive over exactly the same distance, the same roadbed, running on the same time, hauling the same weight, the conditions being identical in every particular, and the amount of coal used by the Heilmann was 24 per cent. less than the amount used by their best compound locomotive.

A point which was made by one of the speakers was that there was no reason why if we used 16 wheels we should not be able to do just as well as the Heilmann does with its 16 wheels. It seems to me that it would be difficult to conceive a steam locomotive with 16 driving wheels. It would meet with difficulties upon the curves and the rigidity of the steam locomotive is certainly going to be troublesome if we come to make a machine 50 feet long all upon the drivers, and I wish to emphasize the point that every pound of the weight of the Heilmann locomotive is resting on springs, and there is no such rigidity of the wheel base. There is the four-axle bogie at one end which has a flexible arrangement connecting it to the platform above, and a similar bogie at the other end, and there is no such difficulty as regards rigidity of construction as it seems to me would be met with in the steam locomotive under the same conditions. And, furthermore, it impressed me that there is not an exact parallel, for the reason that a part of the 16 wheels counted as belonging to the steam locomotive by the speaker are on the tender and they are not at all effective for traction.

As regards the question of wear, and the statement that one-third of the cost of maintenance, roadbed and locomotive is represented by the destructive effects of the hammer blow and side thrust, I certainly would not dare to make any such figures as that for myself. I got that figure from a discussion which was held recently before the Civil Engineers' Society, and the figure was one which seemed to be agreed upon by more than one speaker. The speaker who named that figure, I think, was Mr. Strong. At any rate it was one whose name was familiar to me as that of a man who had a very wide experience and is a pretty good judge of such matters and whose statement ought to be rather authoritative.

Another point I wish to bring out is this: they made measurements of deflection in crossing bridges in the case of the Heilmann locomotive and in the case of the compound reciprocating steam locomotive, and the deflection measurement showed the deflection in the case of the steam locomotive was 80 per cent. more for the same weight than in the case of the Heilmann, which of course is attributable to this hammer blow effect, and which one of the speakers has pointed out has been found, in the case of a little error in the counterbalancing, to be sufficient to entirely lift the weight of the locomotive from the rails at times, as evidenced by tests at Purdue.

I agree with one of the speakers who said that he thought that our progress was not in spite of but by reason of the big corporations, because I think that such progress in the engineering line as we have been lately making has necessarily been made by these corporations, because they have blocked other people who were trying to go ahead.

The same speaker mentioned the misfortune of losing the flexibility which we had all been attributing to the electric locomotive as compared to others, and that in the Heilmann that flexibility seemed to be lost. It seems to me it would be difficult to find a finer example of the flexibility of electrical transmission of power than is illustrated in the Heilmann locomotive. We can have an engine running at constant speed in one direction, and from that we can get any possible reduction or any torque we desire, and any speed in either direction, and the flexibility is as perfect as is conceivable to my mind. In fact, it seems as though the electric energy were used there as a flexible connecting rod acting through an infinite number of gears, and acting between the source of power and the work that was to be done.
